GARDENING

GARDENING

Illustrated. For Town & Country.

A Weekly Journal for Amateurs and Gardeners.

FOUNDED BY W. ROBINSON, F.L.S.,

Author of "The Parks and Gardens of Paris," "The Wild Garden," "Hardy Flowers," "Alpine Flowers," &c.

"YOU SEE, SWEET MAID, WE MARRY
A GENTLE SCION TO THE WILDEST STOCK;
AND MAKE CONCEIVE A BARK OF BASER KIND
BY BUD OF NOBLER RACE: THIS IS AN ART
WHICH DOES MEND NATURE; CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE."

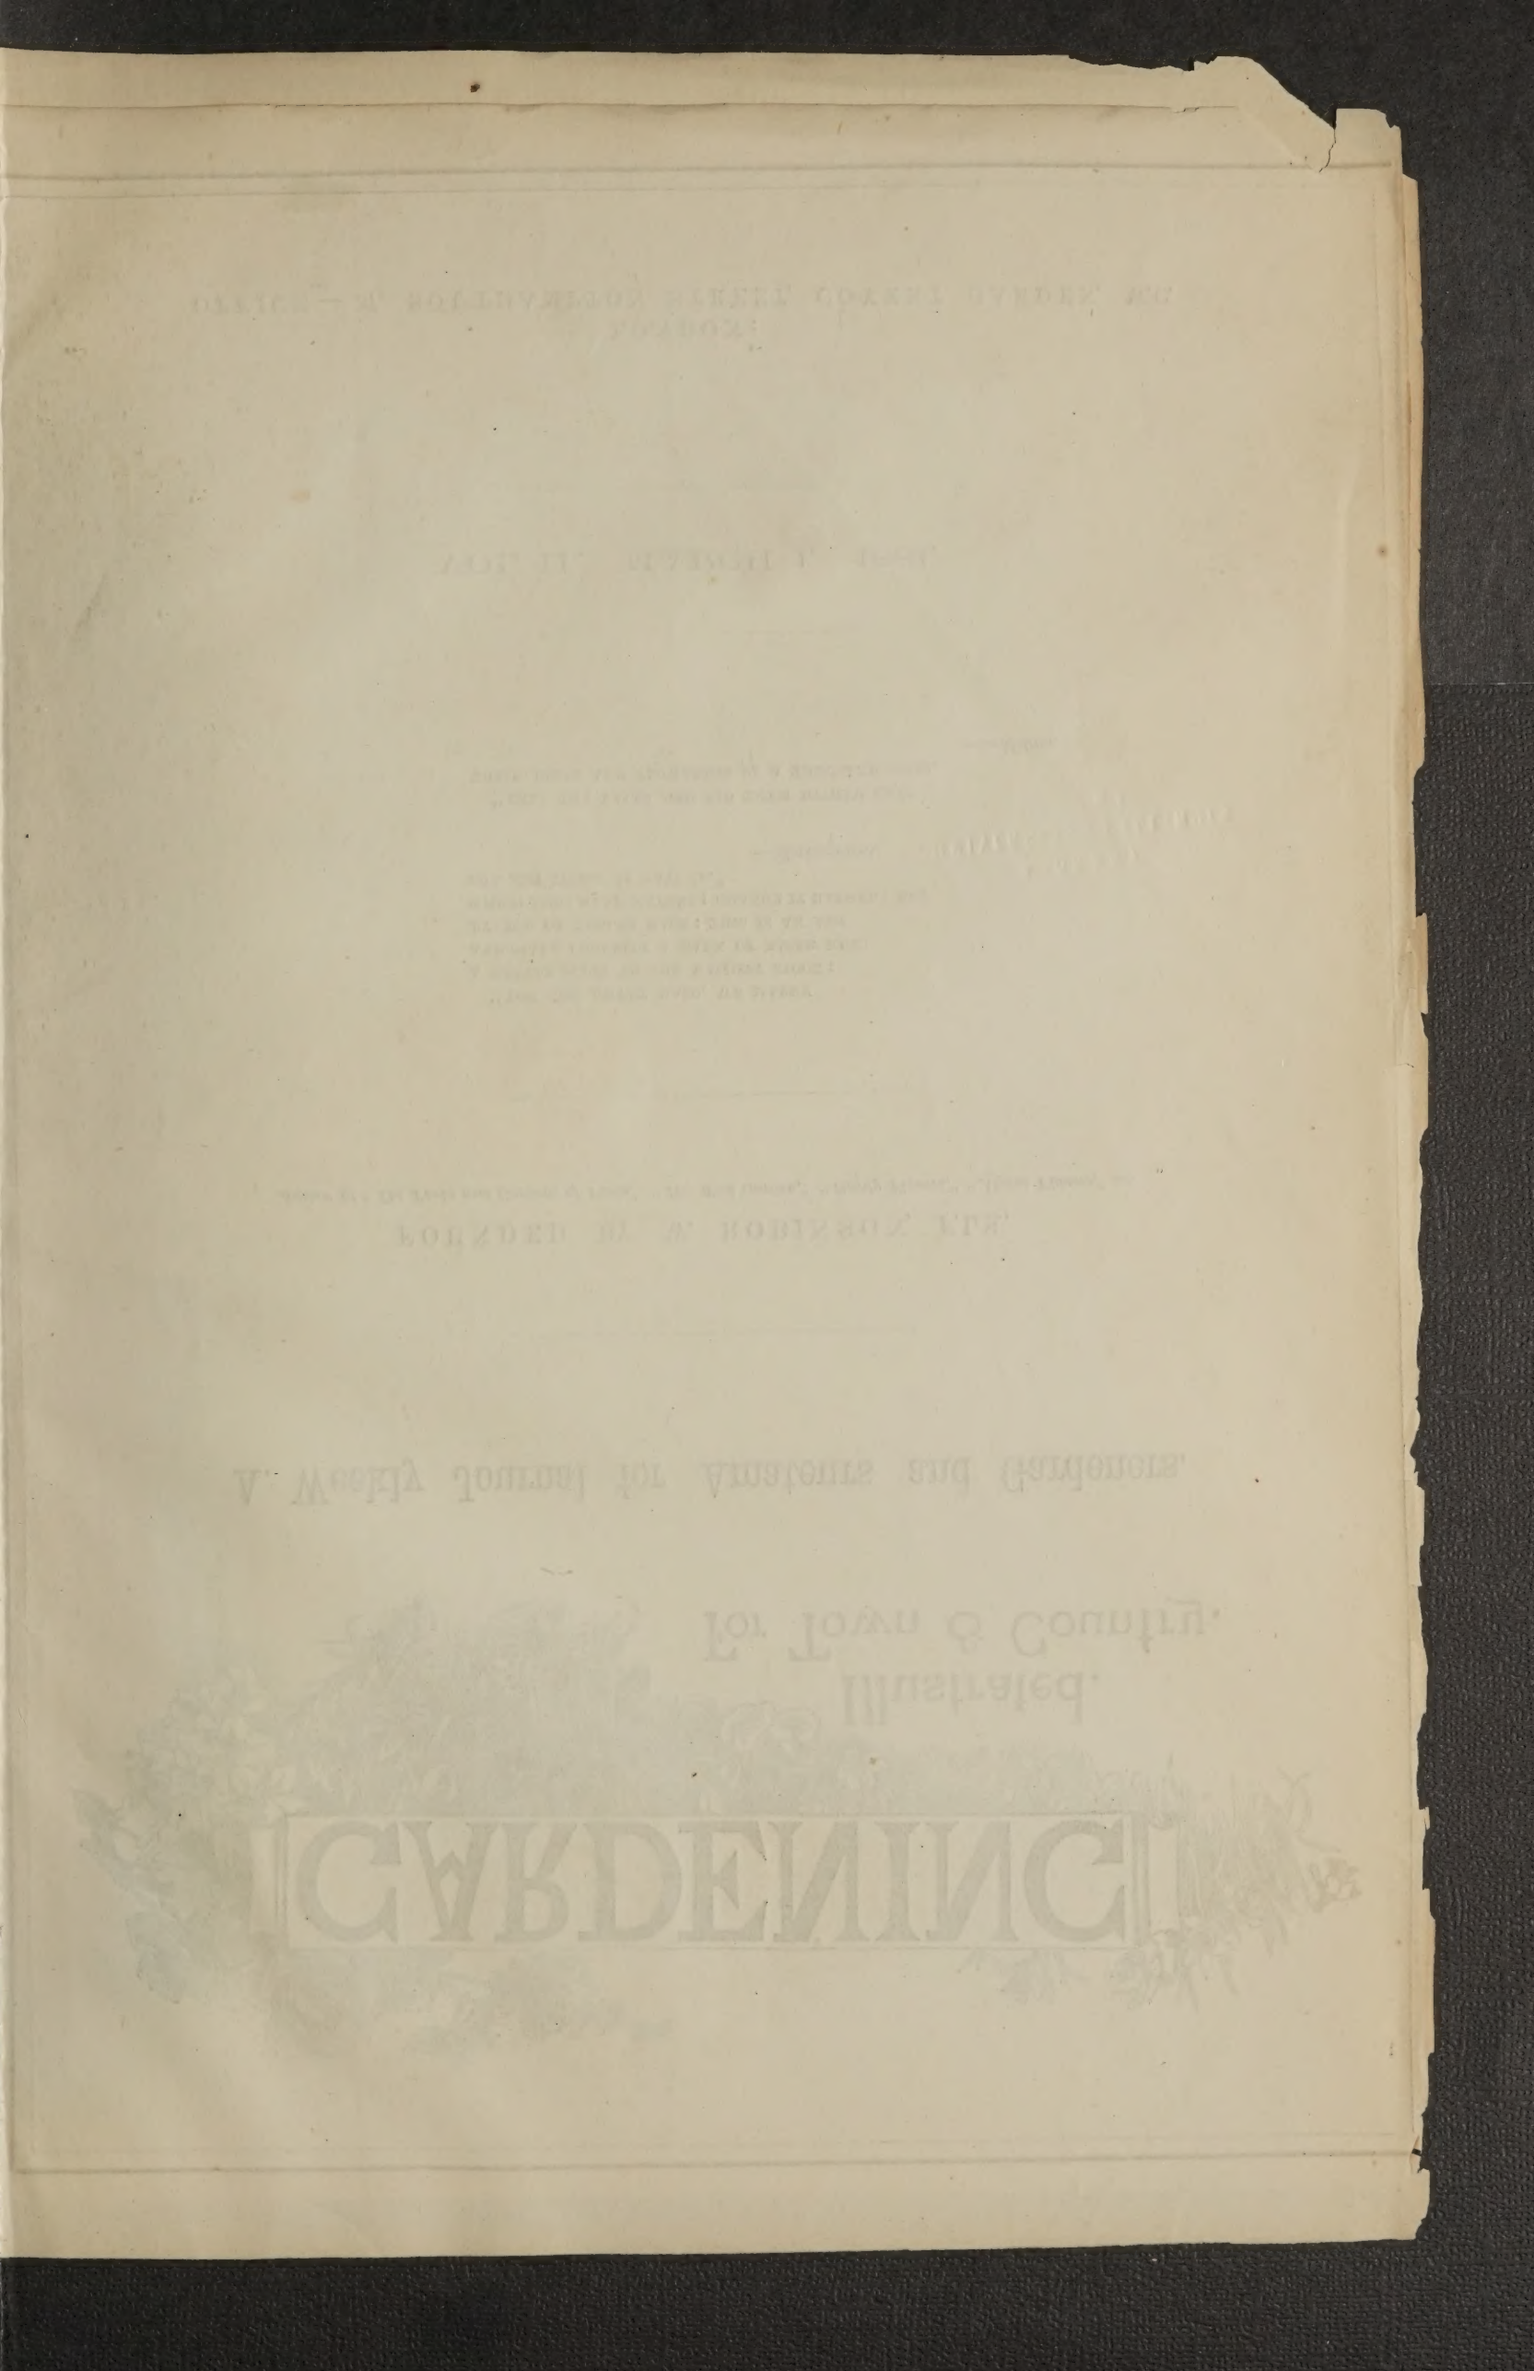
—*Shakespeare.*

"CALL THE VALES AND BID THEM HITHER CAST
THEIR BELLS AND FLOWERETS OF A THOUSAND HUES.

——*Milton.*

VOL II. MARCH 1, 1881.

LONDON:
OFFICE — 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.



GARDENING

INDEX TO VOLUME II.

Those marked with an asterisk (*) are illustrations.

A.

Abutilons, 542
in greenhouses and windows, 321
culture and varieties of, 579
heat for, 95
on pillars and roofs, 79
potting, 114
in windows, 154
*Abutilons, group of, 579
*Abutilon, winter-flowering, climbing, 450
*Abutilon igneum, 450
vexillarium, 7
Boule de Neige, 176
Abronia umbellata, 349
Abrobra viridiflora, 252
Acacias, greenhouse, 450
pollarding, 445
and Cytisus, 176
Acacia, in window, 119
lophantha, 592
insects in tree, 529
armata and Drummondi, 560
Drummondi, pulchella, armata, lophantha, 450
and Pampas Grass, 192
Indian, 325
*Acanthus spinosus, 318
*Acanthuses in bloom, 318, 319
*Acer Negundo variegatum, 37
Achillea tomentosa, 582
aurea, 178
*Achillea Clavennæ, 178
Achimenes, 30, 62
and Gloxinias, 259, 296
drying off, 344
*Achimenes, group of, 367
after blooming, 283
how to grow, 366
for windows, 457
potting, &c., 78
*Aconite, the winter, 496
Aconites, how to grow, 70
under trees, 40
*Aconitum Napellus, 343
*Aconitum variegatum, 343
Acorns for picture frames, 457
in water, how to grow, 561
Adam's Needles and Stonecrops, 453
*Adam's Needle, the Thread-leaved, 111
*Adam's Needle, variegated, 322
Adiantum Capillus-veneris, 164
for covering walls, 416
*Adiantum farleyense, 599
Adiantum farleyense, 167, 385, 457
*Adiantum rubellum, 382, 383
*Æthionema cordifolium, 178
Æschynanthuses, 440
*Agave americana variegata, 43
Agapanthus, 504
Ageratums not flowering, 359
wintering, 445
in winter, 449
for next year, 229
*Agrostis pulchella, 525
*Agrotes lineatus magnified, 292
*Agrostemma cœli rosea, 112
Air giving, 536
Allamandas, 344, 440
in pots, 78
Allspice, Japan, 331
Almond, the, 326
flowering, 457
cream, pudding, and Potato pudding, soup, 326
Almonds to candy, croquantes of, 326
*Aloe, the Pearly, 507
*Aloe, variegated American, 43
Aloes, American, 276
*Alocasia intermedia, 61
*Alocasia metallica as a vase plant, 487
Alocasias, 78
soil for, 168
Aloysia citriodora, propagating, 143
*Alpine plants in front of shrubbery, 17
*Alpine flowers, rocky bed of, 15
*Alpine garden on window-sill, 15
*Alpine plants surrounding a stone, 14
*Alpine plant on stony border, 14
Alpine plants, growing, 13
*Alpine plants, planting, 15
selections of, 16
*Alpine flowers, rock of, 14
*Alpine flowers covering rude steps, 16
*Alpine and rock plants, tuft of, 13
Alsophila excelsa, 405
australis, 405
*Alstrœmeria versicolor, 474
*Alstrœmeria, 378
aurantiaca, 474
*Alstrœmeria puligerum, 475
Alstrœmerias, 306
treatment of, 168
culture of, 474
renovating, 264
Alternantheras, propagating, 337
wintering, 361
Alum plant, the, 23
Amaryllis, culture of the, 78, 97
starting, 572
*Amaryllis Emilia, Ophelia, and Malvolio, 97
Amaryllises, 441, 504
*Amaryllises, new race of, 97
Amarantuses, 114, 570
*Amarantuses, Globe 139
Amarantus caudatus, 588
melancholicus ruber, 463
Amateurs, hints for, 63
greenhouses and what to grown in them, 125
Amazon Lily in small pots, 79
American Cowslips, 360
Aloes, 276
Ampelopsis Veitchi, 415, 578
how to grow, 475
Amygdalus communis, 326
Andropogon Schœnanthus, 563
Anemone japonica, 280
*Anemone japonica alba, 315
*Anemone Robinsoniana, 515
*Anemone, the Snowdrop, 222, 223
*Anemone sylvestris, 222, 223
*Anemones, culture of, 370, 402
planting, 94, 493, 553
in succession, 461
*Anemones, double and single French, 371
*Anemones, Japan, 315
not blooming, 217
from Pau, 337
propagating Japanese, 111
from seed, 40
Angelica beverage, candied, 362
Annual Chrysanthemums, 492
Campanulas, 606
Annuals, Antirrhinums as, 307
Annuals, hardy, 69, 210, 258, 396, 550, 617
August-sown, 258
for greenhouse in spring 271
for greenhouses, 225
tender, for greenhouses, 570
for windows, 141, 613
Annuals for exhibition, 9, 216
two useful, 318
for profit, 382
for bouquets, 10, 20, 22, 47
for Rose beds, 67, 142, 156
for spring, 318, 360
for pot culture, 163, 211
planting out, 107
potting and planting, 168
sowing, 58, 253, 294, 310, 325, 619
raising, 43
thinning, 589
as bedding plants, 66
and biennials, 45
pricking out, 120
treatment of, 445
Antirrhinums, 259, 512
in poor soils, 330
in pots, 216
planting out, 166
late blooming, 539
in winter, 373
as annuals, 307
Ants, destroying, 63
cure for, 149
in gardens, 252, 276
Ants in greenhouses, 418, 517
in frames, 130
in houses, 324
on lawns, 106, 238
in Peach house, 22
and Strawberries, 252
in Cucumber frame, 289
on Palms, 397
and fruit-trees, 143, 155
Anthuriums, temperature for, 119
Antigonon insigne, 433
Anthericum variegatum, 253, 443
*Anthericum Liliastrum, 286, 287
*Aphis, 609
Aponogeton distachyon, 21
not flowering, 143
Apple cookery—pudding, boiled, German pudding, jam balls, moulds, miroton, marmalade puffs, posset and bread and biscuit jelly, pancake, snow, sorbet, snowballs, sauce, French turnover, trifle, 350
Apple jelly, tart, and tapioca pudding, ginger, ginger sauce, beverage, and Pear marmalade, Siberian Crab jelly, Charlotte de Pommes, 362
Apple, bread, batter pudding, and bread pudding, Charlotte and Chestnuts, cake for children, cream, compôte, dumplings boiled, fritters, fool, gingerbread, jelly, pie, 338
Apple stocks, 10
balls, 326
the Ribston Pippin on walls, 365
Small's Admirable, 336
*Apple, the Api, 247
*Apple, the Lady, 247
Apple, Devil's, 408
*Apple grub, the, 501
Apple and Pear trees, pinching, 198
Apple trees, planting, 325, 337, 343
pruning, 265
training, 540
scale on, 81, 94
fly on, 81
not pruning, 445
pruning pyramidal, 373
red spider on, 229
pruning espalier, 300
blight on, 143, 229
moving, 384
bug in, 578
barked, 217
worts on, 491
as a screen, 240
trellises for, 445
liquid manure for, 445
not growing, 168
small standard, 372
from branches, 325
Apples and Pears, gathering, 356
for town gardens, 263
Apples for food, in their skins, Chartreuse of dried à l'Anglaise, 338
Apples stewed to preserve, Siberian Crab, 362
Apples, meringue of, and Rice, Normandy Pippins, preserved Pralinées, and tapioca, 350
Apples, cooking, 326, 350
Apples, keeping from shrivelling, 379
gathering, 316
storing, 326
for town gardens, 253
to keep in winter, 471
and Chrysanthemums, 414
good bearing, 485
kitchen, 384
Warner's King and Devonshire Queen, 331
Apricot cakes, fritters, 362
suckers, 409
trees, 337
Apricots, cooking, 362
and Plums, culture of, 472
laying in young shoots of, 249
grafting Plums on, 144
Apricots, to preserve whole, to preserv green, dried, and Apples, 362
Aquatic plants, 259
drying, 276
Aquaria, cement for, 65, 398
crayfish in, 72
water for, 218
sticklebacks in, 145
Aquarium, stocking an, 83, 108, 170, 278, 302, 614
stocking a bell-glass, 350
difficulties, 362, 290
plants for, 72, 336, 350, 398
how to make and stock an, 59
fish dying in, 278
management of indoor, 398
walls for, 194
white matter in, 170
water turning green in, 83
making an, 241
fountain for, 470
gravel for, 266
*Aquilegia cœrulea, 378
Aquilegias, 127
*Aquilegias, culture and varieties of, 154
in pots, 152
*Aralia Sieboldi, 462
propagating, 70
*Aralia papyrifera, 306
Veitchi, propagating, 117
spinosa, 65
*Aralia japonica, 20
Aralias, wintering, 390
*Araucaria imbricata, 219
failing, 312
losing its branches, 180
Araucarias, soil for, 22, 70
propagating, 313
pruning, 46
Arbutus Unedo, 517
pruning the, 46
Arbutuses, 252
planting, 276
Ardisia crenulata, 30, 164, 515
Ardisias, 392
cutting back, 572
Aristolochia Sipho, 280
Aristolochias, 421
*Armeria cephalotes, 5
*Arrow-head, the variable, 550
Artillery plant, the, 504
*Artichoke, the Globe, 125, 256
*Artichoke, the Jerusalem, 18, 433 521
Artichokes, 445, 469
Artichokes, Globe, 465
Artificial manure for plants, 94
*Arundo Donax, 419
Arum, the Spotted, 306
dracunculus, 11
Arum Lilies, 64, 90, 457
in water, 538, 578
after flowering, 276
treatment of, 407
and Cyclamen, 168
Ashberries, uses of, 310
preserving, 372
and their uses, 379
Ashes for paths, 578, 607
in gardens, 11, 46, 402
*Asplenium nidus-avis, 116
*Asplenium longissimum, 439
fœniculaceum, 462
Aspidium cristatum, 94
Aspidistra turning yellow, 506
lurida variegata, 309, 462
Asparagus forcing, 240, 469, 516
seed, sowing, 341
cutting, 148
near the sea, 215
moving, 217
and Lettuce, 180
prizes for, 33
planting, 52, 220, 240, 493
Kale, 95
cooking, 194
growing, 349
roots, removing, 229
removing old, 553
in borders, shrubberies, and waste spaces, 575

Asparagus plants, moving, 445
beds, 185, 192, 373
salting, 481
weeds in, 130
filling blanks in, 204, 445
making, 227, 421
renovating, 168
Asphalte walks, 364
making, 196
for walks, 215
*Aster, pyramidal, 50
Chrysanthemum-flowered, 51
*Aster, large Pæony-flowered, 49
*Aster, quilled, 50
grandiflorus, for conservatory, 502
seed, saving, 408
*Asters, 370
and Silenes, 578
and Stocks, planting, 201
thinning, 236
in vases, 462
culture of, 463
annual, 49
exhibition, 287
German, sown in open ground, 111
sowing, 22, 68
blight on, 253, 324
*Athous haemorrhoidalis, 292
*Aubretia purpurea, 222
Aubretias, culture of, 222
notes on, 116
Aucubas, for windows, 534
Auricula seed, sowing, 309
Auricula, properties of the, 288
*Auriculas, 19, 126, 251, 417, 440, 456, 465, 469, 528, 584, 608
Auriculas, after blooming, 188
out-of-doors, 74
in bloom, 78
notes on, 547
for exhibition, 66, 91
watering, &c., 68, 476
potting, 181, 368
dividing, 217
sowing, 152
soil for, 488
offsets in, 421
woolly aphis on, 456
fly on, 163
surface dressing, 596
in winter, 573
in towns, 464
propagating, 130
hardy Alpine, 392
Australian Cress for bedding, 144
Auticlea glauca, 481
Aviary, birds for, 72
*Azalea mollis, 593
Azalea mollis and sinensis, 587
Azalea procumbens, 156
cuttings, 130
Azaleas, 31, 429
dying, 577
growing too soon, 130
not blooming, 228
turning brown, 276
losing their leaves, 457, 469
*Azaleas, hardy, 503
Azaleas and their culture, 203
watering, 417
trailing, 156
white, out-of-doors, 222
tying, 344
housing, 361
propagating, 346
after flowering, 102
fresh soil for, 325
hardiness of Indian, 72
for greenhouse, 107
manure for, 612, 623

B.

Babianas, potting, 477
*Balsam, Carnation-flaked, 44
*Balsam, Carnation-striped, 44
*Balsam, Camellia-flowered, 587
Balsams, 114, 296, 570

VOL. II.—No. 52. *SATURDAY, MARCH* 6, 1880. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

EVENING PRIMROSES.

THESE are amongst the most showy and healthy of late summer blooming plants, and surely about the easiest grown. From June onwards they are in their glory, but many species and varieties in late summer, from increased growth, of necessity become more glorious. Amongst them we have tall-growing sorts like Œnothera Lamarckiana and fragrans, and decumbent carpets, as in trichocalyx and cæspitosa; white flowers, as in the last named two, coronopifolia and speciosa, often changing with age to pink or rose; and few plants have more brilliant yellow blooms than those of missouriensis and Lamarckiana, besides, they are so big—4 in. to 6 in. across. Nearly all are more or less fragrant, fragrans, cæspitosa, marginata, and eximia being particularly odoriferous. As a truly hardy and neat perennial, fruticosa var. linearis is one of the best, its little bright yellow flowers being profusely borne all summer, but most lavishly in June and July. All are not equally fond of the night, as their name might suggest, for many species are open by day, as, for instance, Œ. linearis, speciosa, taraxacifolia, and trichocalyx. Many of our finest evening Primroses are natives of west of the Mississippi States, as California, Utah, Missouri, and Texas, and, consequently, several are not quite hardy here. It is advisable to winter the more tender sorts—biennials or perennials—in frames, and where practicable save seeds and raise seedlings annually. They all bloom the first season from early seedlings. Some of the true perennials, and particularly the prostrate-growing ones, are shy seeding, but the tall growers seed freely. Evening Primroses will grow in any good soil, the richer and deeper the better. Even in window boxes some of the dwarf varieties might be grown with excellent results. The annexed illustration, which is one prepared for the new edition of the "Wild Garden," is an attempt to show the right effect of a colony of the large evening Primrose naturalised on the margin of a wood. These noble and delicately-scented flowers are very easily grown and very beautiful in any position. They, however, from their height and boldness, and the freedom with which they grow in almost any soil, are peculiarly suited for the wild garden, for shrubberies, copses, and the like, sowing themselves freely. In this case they are apt to become eventually somewhat too numerous and somewhat "starved," so that where confined to large groups in good ground they are best. In any flower garden not confined to flat beds only, a small isolated bed of these Œnotheras looks well. Such may be seen in the Emperor of Austria's garden at Laxenburg—this being a favourite flower there. It tells very well in the evenings in these beds—4 ft. wide—on the turf, near the margin of a shrubbery, or near groups of specimens on the Grass.

The large Evening Primrose (Œnothera Lamarckiana), in flower at night.

DECIDUOUS WALL PLANTS.

THE deciduous section of hardy climbers furnishes us with a better and more varied list of suitable subjects than the evergreen section. The Clematis almost deserves to be named first. All the varieties mostly, and they are now numerous, thrive in almost any soil and in the most exposed situations, both in England and Scotland. For covering high or low walls or fences, or for draping trees and similar purposes, they are unequalled; they grow rapidly, and flower early and profusely. C. Jackmanni, one of the first raised of the new race of hybrids, is still one of the best for general planting. It flowers most profusely, as most of the varieties do, good plants being generally covered with masses of rich purple flowers of large size. The size of the flowers is, however, much influenced by culture, frequently measuring 5 in. or 6 in. across when the plants are grown in a good soil. When the Clematis is grown against a wall it may soon be made to reach the top, and spread out laterally as well, so as to cover a large amount of space if the quick-growing and rambling shoots be carefully trained, for they soon run into an inextricable bundle if not watched and nailed as they grow. After the plants have covered the space allotted to them they need less training, but should be pruned in closely every winter. Young plants should also be cut well down for the first year or two, in order to induce strong growths and good flowers. An ordinarily good garden soil, well manured, suits admirably, but fresh manures must not be placed close to the roots. When planted to cover rooteries, trees, or fences, the great point is to give the plants a good start by planting them in rich soil; but after they get up they are almost better left to themselves to grow as they please. In such situations slugs are sometimes very troublesome, as they eat the young buds as fast as they grow; and we are not sure that field

mice do not also eat them. The only preventive is watching and trapping till the young shoots get woody and strong, and they should not be cut down too near the ground when pruned. The list of varieties is a long one, and new ones are being added to it; but among the best may be named: C. Jackmanni, purple; lanuginosa, light blue; rubella, claret; Fortunei, white; Lawsoniana, reddish purple; Mrs. James Bateman, lavender; rubro-violacea, maroon; Lord Londesborough, rich mauve with dark stripes; Otto Frœbel, blue and white; Miss Bateman, white; Lady Caroline Nevill, bluish-white; Henryi, cream colour; Star of India, violet-purple; Vesta, an early-blooming white variety, with fine large flowers.

The Virginian Creeper (Ampelopsis Veitchi or A. tricuspidata), is a beautiful wall climber, which, though introduced a dozen years ago, is still but imperfectly known. It is one of the neatest and most attractive of wall plants, is perfectly hardy, and grows fast. A plant of put out against a wall two or three years ago is now some 20 ft. high, and is the admiration of everyone who sees it. A few others, planted only two years ago out of 3-in. pots, are now near the top of a 12-ft. wall. It is the neat habit of the plant, and the fresh green foliage which changes to dark chocolate in autumn, and later to bright crimson, that render it so attractive. In habit we can only compare it to the neatest growing of the Ivies. The shoots adhere to the wall so closely, by means of their little tendrils with holdfast-like appendages, that a pin-point can hardly be inserted between the wall and the leaves, which are placed alternately, and so closely as almost to overlap each other. The warmer and sunnier the exposure, the better coloured will the foliage be; but the plant itself thrives famously in open situations against trees, and soon clothes their stems with a verdure of changing hue. It succeeds best in a good rich light soil; and after it has once laid hold of the wall it wants no further attention in the way of training or nailing.

The common Virginian Creeper (Ampelopsis hederacea) is well known as one of our best climbers, and is particularly valuable for covering arbours and fences, owing to its rapid growth and abundance of fine foliage, which also changes to crimson in autumn, though it does not approach A. Veitchi in that respect. It is, however, so accommodating in its habit, that it can be trained in almost any fashion, the long supple shoots bending and twisting easily in any direction. It succeeds in any common soil. Aristolochia sipho is a quick-growing plant, and its ample leaves render it particularly useful for covering arbours, summer-houses, and similar structures. It is a native of North America, and is very hardy, growing fast in exposed situations even in the north, where we have seen it employed for covering trellised work in the open grounds. It prefers a light, well-drained soil, and the shoots should be tied in as they grow, to prevent them getting into confusion. With the Wistaria we are all familiar, and as a handsome flowering wall plant it is unequalled. There are two or three varieties of it, but the blue and white are the best; and of these two the blue is the most vigorous grower and freest flowerer. One plant, if placed in a tolerably warm situation against a wall, may be trained so as to cover an enormous amount of space in a short time. There is a plant at Archerfield, in East Lothian, which, if we remember rightly, runs nearly the length of the garden wall, some 150 ft. or 200 ft., if not more. It needs a well-drained site, a good soil, and plenty of root-room, and it will grow freely on any aspect except the north. It is not a confused grower like the Clematis, but requires to be trained carefully as it grows, in order to cover the wall quickly and uniformly. The shoots may be bent in any direction.

There are in gardens about ten or a dozen varieties of Honeysuckle in cultivation, but the best are what are called the common white and the red, viz., Lonicera Shepherdi, fragrantissima, scarlet Trumpet, and the now well-known L. aureo-reticulata, or variegated-leaved variety. For general planting, the common native Honeysuckle is the best. In the shade the flowers are more delicately coloured and pretty, but in exposed situations they are more fragrant. The Honeysuckle needs little attention; indeed, it flowers best when left quite undisturbed, and as for training, the less it is meddled with the better, after it has covered the objects it was planted to hide. It is an excellent subject for archways and bowers, and it may be trained so as to drape the branches of trees in a very ornamental manner. Indeed, it usually makes itself at home amongst the branches without any assistance in the way of training, and it seems particularly partial to the Hazel, which it coils itself round in the most regular manner, embracing it so tightly that it checks the circulation of the sap, and the bark consequently swells out and over the stem of the Honeysuckle, as it does over a ligature, the result being a spirally-fluted rod, much sought after by the woodman for making walking-sticks. Among other miscellaneous subjects suitable for our purposes may be named different varieties of the Rose, notably Gloire de Dijon, the Ayrshire, Banksian, and Boursault Roses; the hardier Grape Vines; and Bignonia radicans. Among herbaceous and annual climbers the following will be found exceedingly ornamental and of easy culture: Calystegia pubescens, Convolvulus, Tropæolum speciosum and canariense, Nasturtiums of the Tom Thumb and Lobbianum class, and the usual seedling varieties, Scarlet Runners, and Sweet Peas—all of which may be employed with success and good effect to cover rustic fences or rooteries.

Unsightly Hedges.—Gardens are oftentimes bounded by hedges which, owing to neglect at some period of their existence, have become unsightly and naked at the base. In such a case the best plan would undoubtedly be to grub them up and plant afresh. Owners or tenants are, however, often loth to do this, owing to the expense and the time which must elapse before the plants attain the height necessary to insure shelter and protection against intruders. If the following instructions are carried out, there will be no need to disturb any portion of the existing fence, and in the course of two or three seasons a beautiful ever-verdant, impenetrable screen will be formed. Take out the soil on one side of the hedge about 2 ft. in depth, and then, having procured a quantity of long Ivy shoots, lay them in to the depth of the trench, with the points turned in towards the hedge. Fill in with good soil, or mix some manure with the old. Tread firmly, and if the weather should be dry, give a good soaking of water. September is the best time for planting, but it may be carried out now. The first year but little growth will be made, but the second season, having fairly laid hold of the good soil, long strong shoots will be made, which will have to be trained in the desired direction. Eventually the Ivy will quite fill up all thin places and unsightly gaps and become an evergreen wall. If the top shoots of the Quick are allowed to grow freely every year, the latter will not perish, but will sustain the Ivy for any length of time.—J. C., *Byfleet.*

Hardy Passion-flowers.—In the garden of the late W. Wilson Saunders, at Worthing, the three following Passion-flowers grew and flowered freely: Passiflora cœrulea, glaucophylla, and incarnata. They all grew facing south, and had no protection during the winter. The first-mentioned was trained against a trellis-work screen, and flowered as freely on the north side of it as on the south. In sheltered spots in Worthing the P. cœrulea is profusely covered with both flowers and fruit. These three species are decidedly perennial.—S. S.

WALL ROSES.

There are not many positions in which Roses are grown where they are more effective than against walls when they are well managed. The protection also thus afforded to the Tea-scented varieties is likewise very favourable to their being so grown. Nevertheless, judging from the condition in which they are often seen, Roses are frequently the least inviting of all wall plants. This arises from several causes, which may be enumerated as follows:—First, the selection of unsuitable kinds; second, after a few years the soil in which they are first planted becomes exhausted, and sufficient means are not taken to enrich it; another is unskilful training, which in the case of strong-growing sorts permits the lower portion of the wall, if a high one, to become bare of young flower-producing shoots. The prevalent reason, however, of such an unsatisfactory condition of wall-trained Roses is the difficulty of keeping insects in check. Roses more than the majority of plants are very susceptible to the attacks of insects when trained to a wall—pests to which they are more particularly subject, viz., aphides, red spider, and the rose-maggot. The difficulty in having the plants free from the worst of these pests is greater under these circumstances on account of the walls offering an obstacle to the application of any kind of liquid for their destruction excepting clean water, as most of the insecticides used in a liquid state, including Tobacco-water, leave an objectionable appearance on the walls unless washed off with clean water before it is allowed to become dry, in which case whatever is employed to destroy the insects is also washed off the plants before it has effected the desired object. Since, however, paraffin in a very diluted state is proved to be such an effectual insecticide without injuring the plants, and at the same time is cheap, and also does not leave traces on the wall, it answers the purpose well, and thereby the worst drawback connected with the culture of wall-trained Roses is overcome. Within the last year or two I have regularly applied it against a light-coloured wall, where anything that left a mark could not have been used. Prevention is always better than cure, and as soon as the Roses are pruned and nailed or tied to the trellises, they should have a good washing by either syringe or garden engine with paraffin-water, for, although it may be supposed that severe frosts destroy the eggs of aphides, yet that is not the case. One recommendation which Roses against walls possess is that, except in the most unfavourable parts of the country, they thrive better on east, or even northern aspects, than they do on the southern, which is no small advantage, for on a northern aspect there are few other plants that will flower successfully. As to the sorts suitable for walls, much depends upon the height and space to be covered. Any of the strongest and free-growing Hybrid Perpetual varieties may be grown, as well as the more commonly planted Tea-scented kinds; but there is much to be said in favour of the latter, such as their more continuous habit of flowering and their handsomer, better foliage, besides the fact that

when well managed they succeed better against a wall than in the open, which is just the reverse in respect to the Hybrid Perpetual kinds. Many a gloomy-looking and unsightly north wall, instead of being an eyesore, might be made attractive if clothed with well-selected Roses and carefully attended to. But for this purpose, more than in any other position, it is requisite that the plants be either on their own roots or grafted very low, for unless young shoots are produced annually from the base, the essential point to a well-furnished wall is absent. Whatever yet remains to be done with regard to planting Roses should be completed with as little delay as possible. T. Baines.

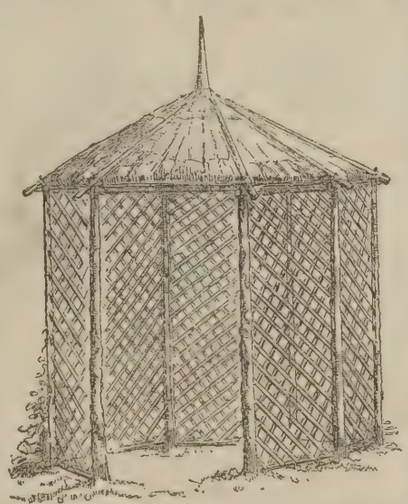
The Best Method of Catching Snails, Slugs, &c.—Having a large, old-fashioned garden, with Ivy-covered walls, sad havoc was for several years made by these pests. I tried Cabbage and Lettuce leaves, pieces of Carrots, Turnips, Potatoes, Apples, Pears, Cucumber, and Bran, but without real success. One day I found a piece of Orange-peel with nine slugs comfortably inside it. This was a discovery. Afterwards I set my trap with it as follows: making a small hole in the ground a little larger than the Orange-peel, putting the pith side downward, then laid over lightly a piece of old wood, if damp all the better, and going my round before the sun was on frequently finding sixty or seventy in one trap, thus getting rid of thousands.—Robin Hood.

Impressions of Leaves.—These may be obtained in the following manner:—Get a small quantity of printers' ink (coloured if possible); make a little ball or pad of cotton, and cover it with a piece of waste silk; dip this into the ink and daub it for a while on a flat surface, such as a piece of slate, till the ink is level all over it; now pat it gently over the entire leaf-surface, next place the leaf on the page of your scrap-book; over it lay a sheet of paper, and rub gently with the point of the fingers, taking care not to shift the leaf in the process, and a very fair impression will be the result. Another plan to obtain an effective picture with Ferns and leaves, and one more suitable for a scrap-album, is to arrange the Fern fronds and leaves on the desired page as tastefully as possible, leaving ample space between. All around the page place waste sheets of paper, and get some permanent-coloured ink—say violet or brown—a tooth-brush, and a knife. Dip the tooth-brush in the ink, and hold it above the page you have arranged, draw the edge of the knife-blade smartly from point to hilt of the brush along the top of the hairs. The result will be a whole shower of minute ink dots. This process is called sparkling. You continue moving your brush, so that the dots may fall just where you want them till your page is quite darkened at the base of your bouquet, taking care, however, to lighten your sparkling outward towards the tips, and causing it gradually to disappear a little beyond them. Some practice is necessary to thorough success, but the result is well worth the trouble.—R. F.

—— I submit the following as a very good way to take impressions of leaves, Fern fronds, &c., always bearing in mind that open leaves are the best to produce a good effect:—Get some cream-laid paper, well oil it, and lay it aside for a few hours, then hold over the flame of a benzoline spirit lamp or common tallow candle until it receives a tolerably thick coating of soot; lay the leaf upon this, and cover over with a piece of paper, and rub the fingers over it. This done, take the leaf and lay it carefully on your album paper; cover over as before, and rub rather more firmly over every part; but do not use too much pressure, or you will damage the leaf. Take care while rubbing that you do not shift the leaf, or you will not get a good impression. Paper with a glossy surface is better than any other kind. I have taken some excellent specimens in the above manner.—Printer.

Guano is an excellent manure for Raspberries applied to the surface with a little vegetable soil, or as an assistant to a light dressing of stable manure, and if there is a deficiency of the latter a little good guano will be an excellent substitute; but in the purchasing of this it is necessary to be careful, remembering that there is no such thing as a cheap article under the name. When it is offered below the current price, either wholesale or retail, the chances are that it is not worth as many pence as you are charged shillings. There is one thing to be observed respecting this manure. If, after trying a sample, it is found good, there need be no hesitation in purchasing a supply that will last for years, for, if kept in a moderately dry shed, it will be just as good in every way at the end of a dozen years as on the day it was imported. We have had it much longer than this, and could not detect the slightest diminution in its strength.

Building a Summer-house.—I have built a very pretty rustic summer-house in this way: Mark out an octagon, each side 4 ft. long; plant at each corner a rough straight pole 4 in. thick and 9 ft. long. Char or double tar 3 ft. of the thickest end and put 2 ft. in the ground. Level the tops, and connect them all round with crosspieces of similar timber, a few inches of each end sticking out. Take another piece 3 ft. long and saw one end to a point; from it, as a centre, nail all round it, like spokes in a wheel, eight straight clothes-props slanting down at an angle of 40.° Put this on the top of the upright poles, and nail each loose prop end to the top of a pole, letting 6 in. or 12 in. extend beyond. This makes the roof. Now fill up with rustic lattice-work (1 in. or 2 in. thick) eight of the sides, leaving one for the entrance: then lattice the roof, or, better still, thatch it. Use strong French nails and the gimlet when



A Home-made Summer-house.

necessary. Fix the crosspieces into the tops of the poles by boring with a centre-bit through the whole, and hammer in an iron peg, 6 in. long. Leave the bark on the wood, which may be sized and varnished. Use throughout the hardest wood possible; Oak or Beech for the poles, and Beech or Hazel for the lattice. Plant a good climber, for instance, scented Clematis, C. Jackmanni, Wistaria, Ampelopsis, Veitchi, scented Jasmine, Honeysuckle, climbing Rose, against each pole; well fill the outside borders with hardy Ferns. In two years you have a floral paradise. My house cost me under £1 without the thatch, but I did all the work myself.—W. L.

Some Good Hardy Plants and Fruits.—At p. 755 of Gardening Illustrated, a mistake has evidently crept in with regard to Apples which may tend to mislead some of your readers. It says, "I am now referring to standards worked on the Quince stock," which should have been the Paradise stock, which is the proper stock to work Apples on, more particularly when they are intended to be grown as pyramids or cordons. But for standards, the Crab stock, or some good free stocks raised from Apple-pips, are far more preferable than the Paradise for this purpose. One or two most excellent kinds might be added to those named in the article above referred to, such as Ecklinville Seedling (or Prizetaker), Grenadier, New Hawthornden, London Pippin, Magnum Bonum, Nelson's Glory, Rymer, Tom Putt, and Warner's King. These are all first-class Apples, good-keeping kinds, constant bearers, and very prolific.—H. R. I.

Cleaning and Colouring Garden Walls.—An important item as regards successful wall tree culture is keeping the walls in good condition by timely attention to stopping and pointing, or filling up the joints both in the brickwork and coping, so that the walls may be kept quite dry, as, in addition to the preservation of the wall, a dry surface will be many degrees warmer than a wet one. For this reason the coping-stones or tiles should have all the joints or openings made good annually with cement. The face of the wall should also be made smooth and even, for holes and fissures offer secure winter quarters for vermin of all kinds, from fly that prey on the tender juices of the leaves, to the earwigs, slugs, and snails that devour the fruit. The winter season is that most suitable for improving walls. The trees should be entirely freed from them, and tied in bundles for safety from breakage or rubbing off of the buds, after which the bricklayer may stop the joints, and then coat the whole surface with thick lime-wash; or if the white appearance is objectionable, a portion of cement or soot may be added. If this be repeated a second time the very worst old nail-battered wall will present a smooth clean even surface and the trees may be re-fastened in whatever way the cultivator may prefer with every prospect of being benefited by the operation; for Moss-grown walls, in addition to looking unsightly and hastening decay, are cold and damp compared with walls treated in the manner just described. The operation is simple and inexpensive, and is one of those minor matters that make all the difference between good and bad wall tree culture. There are many fruits that can be grown better on open walls than under glass; therefore we must not dispense with walls; indeed, for the production of early vegetables and salads we must always have walled gardens, and in order to make the most of the walls we must keep them clean, dry, and free from holes.—J. G. L.

Gooseberry Caterpillars.—In Gardening for Feb. 7 "H. S. C." says that there is no remedy for Gooseberry caterpillar but laborious hand-picking. I beg to differ from this statement. Let him try the following plan:—When the leaves begin to appear take a garden-syringe, go round each tree, syringe the fork and the stems of the branches. Into the whole of the wetted parts immediately throw soot so thickly as to cover the stems and branches so wetted. In ordinary seasons on trees thus treated not a caterpillar could be found. If heavy rain washes the soot off, repeat the process. If the trees do not stand on one leg, every part touching the ground must be so treated. I learned the soot treatment a good many years ago, and have never once partially failed until last year, when the incessant rains proved too much for me in a few bushy trees.—W. B. Thomas.

Celery a Cure for Rheumatism.—The Celery should be cut into bits, boiled in water until soft, and the water drank by the patient. Put new milk with a little flour and nutmeg into the saucepan with the boiled Celery, serve it with bread toasted, and eat it with Potatoes, and the painful ailment will soon yield. It will not suffice to try it a time or two, but it must be continued. Having proved this receipt, I can confidently recommend it to others.—J. J.

Extra fine Varieties of Flowers.—I entirely endorse the opinion given under this head by "F. C." in Gardening, February 7. I and many of my friends have often been deterred from growing a few pots of choicest flowers owing to the fact that the lowest priced packet of seed say of really good Primulas is 2s. 6d. To persons requiring a very small show of these and other most desirable flowers, of which one dozen would be sufficient, the price seems too high. A packet of seed at that price would probably produce—the seed being good and the cultivation correct—several dozen plants, the majority of which would have to be wasted for lack of accommodation. I am quite of the same opinion as "F. C.," viz., that if the best seedsmen would sell quite small packets of the best seeds, equal in every respect to those in the large and higher priced packets, the number of their customers would be very much augmented, and a much wider field of interest opened out to small amateur gardeners, who know how to appreciate

"little and good," and have generally much more real love for the flowers which they have themselves raised and tended than the professional gardener, who, as a rule, merely produces these things to give satisfaction to his employer. —E. G. [We have mentioned this subject to some of the leading seed growers and the following is the substance of their reply: "We find from experience that the choicer the strain of flowers the more difficult it is to save seed, and if a smaller quantity than a half-crown packet is sown, amateur gardeners especially would not be able to raise plants, and would be complaining to the seedsman that the seeds were bad."—EDITOR.]

A Good Winter Vegetable.—After the last two severe winters, which killed many vegetables, one that can be found to withstand all weathers, and at the same time be wholesome, should be largely grown and frequently used in winter. Such a one is the Leek, which, when grown in good rich soil, produces a stem from 9 in. to 1 ft. of clear white and proportionately thick. These when well cooked, and served as whole as possible with melted butter, are delicious. I have used them regularly in winter for several years. To have them good they require to be sown early and afforded liberal culture, in order to induce quick growth before autumn sets in. During severe weather a little dry fern or litter may be shaken over them, not only for protection, but to facilitate the operation of lifting.—A. H.

Continental Vegetables.—Messrs. Jas. Carter & Co., of Holborn, have carried out a good idea as regards good Continental vegetables in offering a select collection of them, which may be had by post. We all know too little of some excellent vegetables grown in France and Germany; this, therefore, is a step in the right direction. We should advise that, apart from this small selection at a fixed price, some of our seedsmen would publish a really trustworthy and complete list of good Continental vegetables, stating their English synonyms when they have any. Many who have travelled wish to get vegetables which they have seen abroad, and though some of these have been sent out of England under new names, we should, for our own part, prefer them under their true names by which they have been known for many years in the places where they are grown.

FRUIT TREES IN PLEASURE GROUNDS.

I CONSIDER that fruit trees have undoubtedly some claim to be considered ornamental. In Germany, where flowering trees and shrubs are held in higher estimation and are more extensively planted than in this country, the line between the fruit garden and pleasure ground is not as a rule so closely drawn as it is the custom to do in England. There one often sees fruit trees intermixed with ordinary trees and shrubs, and I consider that this form of arrangement has much to recommend it. In the first place, the rather cheerless aspect which shrubberies so often present during the early months of the year is much relieved thereby; and then, again, trees thus placed often yield a portion of fruit when those in more exposed situations have been chilled by cutting winds or sharp frosts. I have frequently remarked that an Apple or Pear tree, which by chance has found a place in the shrubbery, has produced fruit when those plantations most relied on have, owing to the inclemency of the season, completely failed. There are probably few more beautiful floral objects than an orchard in full bloom, and few flowering trees or shrubs can rival the Apple or the Pear when loaded with their snowy flowers. When so planted that they are in the near proximity of evergreens, especially such as are distinguished by the sombre hue of their foliage, the effect is very beautiful. I have had the good fortune to reside in some of the finest fruit-producing districts in Europe, and have often thought that nothing could exceed in peaceful beauty the aspect of the Rhein-Thal and Neckar valley during the flowering season of the fruit trees. I have a vivid recollection of once standing upon an eminence in the vicinity of the Vosges Mountains, from whence seventeen villages could be counted, each one embowered in fruit trees, and lying snugly in valleys surrounded by hills, clothed with lines of sombre hue, the whole forming a scene worthy of the most gifted painter's brush. The valley of the Neckar is also extremely beautiful during the month of May, studded with little hamlets, nestling in the shelter of the hills and surrounded with fruit trees of fine proportions, thus forming a series of delightful floral pictures, of which the eye never seems to weary. In the palace gardens of Ludwigsburg there are whole avenues of fruit trees, which, so far from appearing misplaced, rather seemed to add to the attraction of the place. It is certain that there are many situations in gardens in this country, such as in the wild garden, the shrubbery, or the half-annexed portion of the pleasure ground, where a few fruit trees might be introduced with pleasure and profit to the owner. There are, of course, some varieties which by their vigour and manner of growth are better fitted than others for the purpose, and only such should be planted.—J.

Pæonies.—These are plants of easy culture, accommodating themselves to every description of soil; they are very hardy, abundant flowerers, and very varied in colour. The best time to plant Pæonies, both tree and herbaceous, is September, and if vigorous plants be selected they will readily produce a few blooms the following season, thereby gaining a year over those planted in spring. They succeed better in a heavy soil than in one which is dry and light. Before planting the ground should be deeply dug, as they have long tap-roots, and if well manured all the better; but the manure should be well decayed, as if fresh it has a tendency to generate root fungi. A shady, airy situation is best for plants of a pale pink or yellowish hue, as bright sunshine injures their colours. The Moutan or Tree Pæonies are excellent plants for indoor decoration when got into flower early in spring. To accomplish this the plant should be lifted from the open ground in September or October and potted, after which place them in a shady position under a wall till the weather becomes cold and wet, then place them in a moist frame or house, and when they have formed plump bloom-buds, put them in a moist temperature of about 50°. They must not be forced till the bloom-buds are formed or they will not flower at all.

Flower of the Moutan or Tree Pæony.

Lily of the Valley in Norfolk.—It is truly a lovely sight to see this growing as it does in a copse near here by the acre, and well would anyone be repaid for the trouble if they could cover bare spots under trees as Nature covers them; and with care and forethought, without doubt, a great deal might be done in this way. When in bloom, immense bunches of these Lilies may be seen in almost any cottage window, just as they are gathered, leaves and flowers together. I also remember seeing this Lily growing in masses in a garden in Hampshire, pushing itself up through the gravel paths; so that it seems it will almost grow anywhere.—J. O.

Chrysanthemum Societies.—We are pleased to see these are extending in London and its suburbs. We find a new society has just started at Finsbury Park; it bears the title of "The Finsbury Park, Hornsey, and Wood Green Chrysanthemum Society." The schedule is as good as can be expected at the beginning; and as the Chrysanthemum is the best of London flowers, and can be grown as well in a backyard almost as well as in a country park, we hope the society will meet with encouragement and success.

THE HERBACEOUS PHLOX AND ITS CULTURE.

AMONGST hardy flowers adapted for the decoration of small gardens, and where means are limited, the Phlox holds a very high place. It is quite hardy, easily propagated, and very easily grown. As a tall-growing plant for the back row of the herbaceous borders, the Phlox is admirably adapted. A place ought also to be found for it in the schedules of flower shows in August and September. What a contrast the symmetrical spikes and beautiful sweet-scented flowers form to the rather formal and lumpish Dahlia. The cut spikes do not last long unless they are gathered on the morning of the show and kept as cool as possible, and the severed ends should not be long out of the water. I have seen a very neat arrangement made by cutting three spikes of one variety and inserting the ends in a potful of very wet sand, but the flowers were considerably faded before the day was out under a close tent. This would have been avoided if three tubes had been inserted in the sand; and it would have added to the effect if the surface of the sand had been covered with green Moss. In the case I allude to there were, I think, twenty-four varieties of Phloxes, three spikes of each variety.

Culture in Pots.—The Phlox is an excellent subject to cultivate in pots. For pot culture take the cuttings as soon in spring as they can be obtained, and if the plants were potted in autumn and wintered in cold frames this will be about the middle of February. The young shoots will then be about 2 in. long, and if the plant is weak three shoots only ought to be left; if strong five may remain. The superfluous growths must be cut out with the point of a sharp knife close to the stem, and each of them may be inserted singly in a small pot, using fine soil. Let the pots be plunged in a gentle hotbed, and roots will very speedily be formed. With a little care each of the cuttings will produce a very fine spike of flowers the same season. The plants must have no check to their growths, but, indeed, there is little danger of this unless the cultivator is careless. Our present subject is a gross feeder, and does not brook restraint to its roots, and as soon as the young plants have made some growth they ought to be potted into 3-in. pots, and when these are sufficiently filled with roots repot again into 5-in. and 6-in. pots.

Soil.—The soil in which the Phlox luxuriates is one of good fibrous loam about four-parts, one part rich decayed manure, and one of leaf-mould. The plants must be kept under glass in cold frames until May, when they may be turned out in a sheltered place out-of-doors. They should be exposed to light and air, but the force of gales must be moderated by a screen such as may be afforded by a close hedge. Each stem must be provided with a neat but stoutish stake, 18 in. long. All through the growing period water freely and syringe overhead when the weather is hot. Manure water is necessary in the latter stage of the plant's growth, but care must be taken not to apply it too strongly. When the flowers begin to open the plants may be taken into the greenhouse.

Planting Out.—When the plants have finished flowering in pots, cut the stems over and place the plants out-of-doors. They must have the protection of a cold frame during winter if it is intended to flower them in larger pots next year; if not, they may be planted out

at once in beds or borders of rich soil. The second year, to do the plants justice, they ought to be potted into 9-in. or 10-in. pots. The ground must be well manured and deeply trenched if the best results are to be obtained. It is not easy to do the plants justice in a mixed border amongst other plants, and if the best possible spikes are wanted for exhibition it is infinitely better to prepare a special bed for the plants. Here they can be watered and receive the special attention they need at the right time. The plants may be put out 2 ft. apart, and allow the same number of stems as already recommended for pot plants. Each stem must have a separate stick, and that must be placed to them early, as they readily snap over close to the surface of the ground in a gale of wind. Mulch the surface of the beds with rotten manure, and apply water freely whenever the dry, hot weather sets in. The best spikes are produced from two-year-old plants, after that they degenerate. A fresh stock of plants should be propagated from cuttings, which method is preferable to dividing the roots. It is not essential to provide a glass shelter for the cuttings, they will strike roots in the open ground, and from this they may be at once transferred to beds. The varieties of Phlox pyramidalis do much better in the north than they do in the hotter districts of the south; indeed, I have nearly discontinued growing these early flowering varieties, although some of them are very pretty, but they are also very delicate. The late flowering section, Phlox decussata, is the best adapted to grow in the south of England, and it has been much improved during the last decade. Mr. Laing, of Stanstead Park, Forest Hill, has probably done more than any one in this country to improve this section. There are also many highly-coloured varieties introduced at intervals from France.

J. Douglas.

Spiræa japonica.—Some say buy imported clumps of this useful plant; but that is not always convenient. Last April I cut each of my plants in four, planted them out in a good border, and the growth which they made astonished me. In September I lifted them, and they worthily occupied 9½-in. pots. Just now I have them arranged round the curb of our two pot Vine houses 80 ft. long; they are one mass of flower, and, putting aside their actual worth, they add quite a finish to the houses.—R. G.

Summer Snowflake (Leucojum æstivum) in Winter.—This can be had in bloom in January. But I would not recommend it to be forced so early, except when white flowers are required. By forcing so early, the spikes of bloom are smaller than those that open in February, when one can have them quite as good as those on plants grown out-of-doors. My plan is to lift the bulbs carefully in autumn without disturbing them much, and to pot them in such a way that the clumps just allow a little new soil to be put in the pots; after potting, I put them into a cold frame or pit until they begin to start, when they are placed in a little warmer place as occasion may require. After blooming I harden them off, and then plant them out-of-doors; but, if need be, they can be divided before planting; they will then be ready for next autumn. If the bulbs be divided at potting time there will be no bloom; indeed, bulbs should not be pulled to pieces, except one wants to get up a stock.—J. C.

Great Thrift (Armeria cephalotes).—This, compared to our British Thrift, is somewhat as the full-blown life-guardsman to his humble congener in the militia. From a dense mass of crowded leaves 4 in. to 6 in. long spring numerous stems 15 in. to 20 in. high, each bearing a large, roundish, closely-packed head of handsome satiny, deep rose-coloured flowers. It is one of the finest and most distinct perennials in cultivation, and should be in every select mixed border, and on every rockwork among the taller and stronger plants. It comes from North Africa and Southern Europe, and, though hardy on free and well-drained soils, occasionally perishes during a very severe winter, especially on cold soils; it should therefore be placed in a warm position on rockwork, and in very well-drained, deep, and good sandy loam. It is known under various names—Armeria formosa, A. latifolia, A. mauritanica A. pseudo-armeria, Statice lusitanica, and S. pseudo-armeria. It is, fortunately, easily raised from seed; and, as it is not easily increased by division, it is a good plan to sow a little of it every year. Varies a little when raised from seed, but all the forms I have seen are worthy of cultivation.—W.

The Great Thrift (Armeria cephalotes).

BEDDING PLANTS FROM SEEDS.

The present and the last winters have proved very disastrous to those who, without much convenience for wintering plants, have succeeded in ordinary winters in carrying some safely through the severe weather. This can be done in an ordinary winter; but where it is of an unusual character, with biting winds, intense frost, long-sustained and raw fogs, that are worse than the frost, it is very trying indeed, and the plants nursed with so much care soon perish utterly. There are many amateur gardeners who find themselves in such an unfortunate position. It is disheartening work, but the loss is not altogether irreparable, for there are seeds of many useful plants which, if sown in early spring in a little warmth, will be found of great service during the coming summer. In this way foliage and flowering plants alike can be obtained.

A list of useful flowering subjects will, no doubt, prove acceptable, and it will come as a seasonable reminder, as this is the time of year when the seeds should be secured ready for sowing. The dwarf Ageratums come first, and of these there are Imperial Dwarf, Countess of Stair, and Lady Jane, the last for choice, because it is a newer variety, and a superior, distinct, and compact form, with dense green foliage and a robust constitution, growing from 12 in. to 14 in. in height; the flowers are of a bright blue colour, and are produced in abundance throughout the season. The double white and the double golden forms of the annual Chrysanthemums—C. Dunnetti—are very useful subjects in the garden, and if the plants are kept pinched back in the early part of the season, they will grow into close, compact bushes and yield an abundance of flowers, which, in addition to their decorative value, are very useful for cutting from. The pretty Collinsia violacea is a charming plant in the garden, though its duration of bloom is not very great; but for a time, at least, it is very pretty and effective. There are several forms of the Indian Pink that are most useful in a garden; indeed, they are so thoroughly good, that to properly enforce their claims they should have a chapter to themselves. The double Indian Pink, with its great variety of colours, and the rich dark blood-purple selection known as atropurpureus, are delightful things, blooming with remarkable freedom and of a lasting character. No one unacquainted with this race of hardy annual Pinks should continue in ignorance of their great value for cutting from. Then there are Dianthus Heddewigi, D. laciniatus, and D. diadematus, all very fine and improved forms of D. chinensis, each of which has its double counterpart. A pinch of mixed seed will give a great variety of colours, but it is found that selected types come true from seeds. Two of the latest and finest of these are Eastern Belle and Crimson Queen, the last a very fine crimson-flowered laciniated variety. Many cultivators would find beds of these very acceptable during the coming summer, and the plants should have good soil and be afforded plenty of room in which to grow. It is a mistake to crowd them too much. Godetia Lady Albemarle makes a very attractive bed; the flowers are large, finely produced, and richly marked, displaying themselves to the best advantage. There are some very fine selections from this of a peculiarly handsome character. The dwarf varieties of Helichrysum, though not so showy as some of the subjects named, are yet worthy of a place in the garden, being dwarf and branching, and very free. They also are very useful for cutting from, and if a nice bunch or two of flowers of the brightest colours be cut when the blooms are about three parts developed, and hung up in a dry cool place with the flowers downwards, the stems will stiffen, and the dried flowers come in very useful for winter decoration within doors. The dwarf Larkspurs also are singularly beautiful as well as pleasingly varied in colour. There is a danger of this fine annual flower being too much neglected, and a bed of them is a delightful change from the ordinary subjects which find a place in the summer garden. Parson's white Mignonette makes a sweet bed, but it is

of no use to put the plants in poor soil. Cultivators often do the Mignonette an injustice by putting it into poor soil, where it drags on a half-starved existence, and produces only inferior and shabby spikes of flower. Only let the plants be put out thinly into well-manured soil, and the result will be eminently satisfactory. The pretty coppery-scarlet Mimulus cupreus makes a very acceptable bedding plant, and in good soil forms a dense growth and furnishes an abundance of blossoms, and, unlike the large-flowered selections of M. maculosus, is much more continuous in bloom. Then there are the dwarf Nasturtiums, which, though best adapted for bedding purposes where raised from cuttings, are yet very serviceable when obtained from seeds. There are first of all the ordinary Tom Thumb types, which are of coarse growth and with a tendency to hide their flowers in their foliage. The improved varieties, such as Luteum Improved, Beauty of Malvern, Lustrous, Bedfont Rival, &c., make fine beds with handsome and richly-coloured flowers, and as they seed sparingly are more continuous in bloom. When a gardener gets a good type of any of the latter, he should be careful to put in a few cuttings in August, so as to secure some stock plants to propagate from in early spring. Rhodanthe maculata makes a very pretty bed indeed, and Everlastings are always useful. To do the Rhodanthes justice they should be in a light, warm, rich soil. Silene pendula and its dwarf variety compacta are well worthy of justice, and furnish very pretty and durable summer beds. Marigold (Tagetes) aurea floribunda is an invaluable summer-bedding subject, and quite takes the place of the yellow Calceolaria. Unfortunately, there are very poor and spurious stocks of it in cultivation. Only let a good strain be once secured and the gardener can raise his own plants from seed annually. The last subject is Verbena venosa, a valuable bedding plant, which can be raised from seed, and, being a perennial, preserved from year to year. It makes a very fine and durable summer bed.

Of foliage plants adapted for bedding which can be raised from seed, there are the useful Amarantus melancholicus ruber and the distinct drooping A. salicifolius; Celosia Huttoni, with its fine habit and effective colouring; Centaurea ragusina and its variety compacta, the seeds of which should be sown at once in a gentle heat, and the plants grown on into size as fast as possible; Cineraria maritima, a very useful silvery-foliaged bedding plant; Humea elegans; Oxalis corniculata rubra, Perilla nankinensis, Pyrethrum Golden Feather and the handsome cut-leaved variety laciniata. To these can be added Dell's crimson-leaved Beet and the variegated broad-leaved Cress. There are other fine and useful foliage plants, such as Cannas, Chamæpeuce, Nicotiana, Ricinus, Solanum, and Wigandia, but they are better adapted for subtropical gardens, and require special treatment.

Of the flowering plants enumerated, a few of them might be objected to on the ground that in regard to the period of blooming it is not of a very prolonged character. But it is not difficult to raise successional batches of plants from seed, and so have in hand relays of plants to put out as required. Some of them could be grown on in pots to a size when they would begin to develop their flowers, and by so doing the breaks in the floral succession would be of the briefest character. R. D.

Grevilleas from Seed.—Where these elegant plants are raised from seed I have not found it very material at what time they are sown; it is, however, well to get them up early, and if the seeds are now put in it gives an opportunity for their attaining a useful size during the season. Seedlings are in some respects preferable to struck plants, and by raising them from seed there need be no stint in the numbers; their graceful Fern-like habit is such as to make them deserving of being grown in quantity, not only for the purpose of table decoration, for which few more plants are more appropriate, but also for mixing with greenhouse plants either in flower or possessing massive foliage. Seed sown in a pot or pan of well prepared fine peaty soil, to which has been added sufficient sand pressed smooth on the surface, soon vegetates. The seeds should be distributed evenly, and a little fine sandy material should be put on them. They should then be covered with a bell-glass, or a piece of glass should be laid on the top of the pot, which should be placed in a moderate heat. It is not absolutely necessary to cover the seeds of these or similar plants with glass, but there is an advantage in thus being able to keep the soil in a moist condition without often applying water, and the less that has to be given before they vegetate the better.—A. Z.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 11.—Sowing the main crop of the following sorts of Onions, viz., Early White Naples, Improved White Spanish, Bedfordshire Champion, Danvers' Yellow, and James's Keeping. Putting in cuttings of Tomatoes. Planting out Potatoes in frames previously brought forward in pots. Planting Selected White Spanish Onions for seed; also a few Beet and Early Nantes Carrot.

March 12.—Sowing Mustard and Cress; also Parsley and Early Frame Radish. Putting in cuttings of Alternantheras, Coleus, Mesembryanthemums, and Salvias. Potting off Melons, Heliotropes, Petunias, and Verbenas. Transplanting autumn-sown Onions and Red Cabbage plants. Lifting some large crowns of Victoria Rhubarb for making a new plantation. Renovating the linings round manure frames. Looking over the Strawberries in bloom. Removing all weak plants and cutting out all the weak flowers.

March 13.—Putting in cuttings of scented Verbenas, Pelargoniums, Gardenias, and Fuchsias. Potting off Iresine and Ageratum. Planting out Brown Cos Lettuce plants from the autumn-sown bed; also a few Cauliflower plants. Giving Cucumbers a little earthing. Looking over the Grapes in bottles, cutting out bad berries and filling up the bottles where required.

March 14.—Sowing the following sorts of Peas, viz., William I, James' Prolific Marrow, G. F. Wilson, Forty-fold, Carter's Commander-in-Chief, and Sutton's Giant Emerald Marrow. Potting off Alternantheras, Coleus, and Lobelias. Taking up Camomile roots, dividing them, and making a new plantation. Finish the pruning and nailing of Peach trees on open walls. Getting the wire guards put over the Peas and Broad Beans to protect them from jackdaws and sparrows.

March 15.—Sowing Mignonette in pots. Pricking off Celery in boxes and putting them back into warm frames so as to keep it growing. Cleaning out an old worn-out forced Asparagus bed, and put in another. Earthing up Potatoes in frames. Thinning out Carrots and Radishes in frames. Trimming out Pea sticks. Getting soil into manure frames ready for Melons. Getting netting and other covering over Apricot trees for protection.

March 16.—Thinning Grapes, and tying down the shoots were required. Manuring and digging Rose borders. Earthing up Beans in pots. Cutting back and thinning out dwarf Laurel clumps. Tying in some of most forward shoots in early Peach house. Tying up Cos Lettuce, and covering up Endive to blanch. Manuring and digging the ground previously occupied by Brussels Sprouts. Covering up Seakale, and planting Potatoes.—Fruit in use for dessert:—Pines, Grapes, Apples, and Pears.—W. G., *Dorset*:

Roses.

Pruning Roses.—For ordinary purposes Roses should not be pruned too severely, as numbers of flowers are generally more acceptable than a few exceptionally large ones. It is difficult to convey in writing the exact method advisable to follow, as even many individual varieties require to be somewhat differently treated from others; but it may be taken as a safe rule that the stronger the natural growth of the variety, and the more vigorous the state of the individual plant, the less pruning needed, for the obvious reason that a plant in this condition is calculated to support a greater number of shoots with a proportionately larger crop of bloom than one that is weaker, either by accident or the less vigorous habit of the sort. In all cases it is advisable to remove completely out from their base the whole of the weak, thin wood, the produce of last or previous seasons, and which has not sufficient substance to push shoots strong enough to flower; for the presence of these uselessly taxes the energies of the plants, drawing support which is better concentrated in the stout, blooming wood. These weak growths also tend to crowd the plants, keeping out both sun and air. With Roses that are naturally weak growers it is necessary to prune to fewer eyes than in the case of the strong ones, otherwise, if left too full, the flow of sap is directed to the formation and support of a much greater number of shoots than are ever strong enough to bear flowers, to the manifest detriment of those which are. All the Tea varieties must be pruned very cautiously, leaving their strong growths without further interference than being somewhat shortened; but with these, likewise, it is advisable to thin out all the weak shoots. With the weakest growers of the Teas also leave the strongest shoots a considerable length, but reduce the number proportionate to the natural strength of the variety and the more or less vigorous condition the plant happens to be in.

Greenhouse Plants.

Pots containing three or four Tulips, bordered with Club Moss, and set off in the centre with such Ferns as Pteris serrulata, have a beautiful effect, and the same arrangement may with advantage be carried out in the case of Hyacinths. Forced shrubs are now particularly attractive, and should be mixed harmoniously with such plants as are not in flower; amongst them are Lilacs, white and purple; Weigelas, Roses, Prunuses, Thorns, white and scarlet; Spiræas, Deutzias, Acacias, &c. Cinerarias, Cyclamens, zonal Pelargoniums, Chinese Primulas, Epacrises, Heaths, and Fuchsias are also now in great beauty. Plants in general are making fresh growth, and consequently require more water. Prune and tie all that require such attention. Any that are in a backward condition in borders should be moved and have others put in their places. In planting from pots, loosen the ball of soil and spread out the roots, for, although this may occasion a little check for a time, the plants thrive better afterwards. Hard-wooded plants requiring repotting should be attended to at once, and afterwards kept for a time in the closest part of the conservatory. They should not be watered for some days after being potted, but the atmosphere should, if possible, be somewhat damp. Climbers of various sorts should be thinned and tied, taking care in thinning to provide for a free display of flowers rather than a gross production of wood. Large Camellias, which have got leggy from want of judicious pruning when young or through overcrowding, may be improved in the following manner:—Take, at once, a couple of healthy young plants in 6-in. pots of any approved kind, place these on the surface of the ball of the plant to be operated upon; then inarch the heads of each of the young plants as low down as they can be got on the opposite sides of the large plant. These will become firmly united during the summer, when they may be severed from their original stems, and in the following season, before growth commences, the head of the stock may be cut away just above where the young plants have been inarched, when they will commence to grow apace, and in a little time make handsome plants. Moveable shading of thin material should be got ready, as bright sunshine on a March day makes short work of many things in flower. Pinch out the points of a portion of the stock of Pelargoniums. These will be useful in July after the early ones are over. Start another batch of Achimenes, Gloxinias, and Tydæas for summer decoration. See that Lilies breaking through the soil are not left where they have an insufficiency of light, otherwise they make weak growth, which no care afterwards will put right.

Ferns.—The general potting of Ferns should have been done last month, but if the operation has been delayed until now it ought to be at once accomplished. If the plants have begun to grow they will be more liable to suffer from shifting than they otherwise would be, but with careful attention in the way of shading, maintaining an equable but gradually increasing temperature, and supplying a moderate amount of moisture both to root and top, little danger need be apprehended. Ferns whose fronds spring directly from the soil require a richer compost than such sorts as Davallia canariensis, whose rhizomes grow above ground. To the former give a mixture of equal parts of good fibrous peat and loam, with the addition of some leaf-mould, plenty of silver sand, and some small chips of fine sandstone. If the plants be required, however, for furnishing purposes, a little more loam and a little less peat will induce a hardier growth, and one better adapted for hard work than the luxuriant growth promoted by the first-named soil. Those with rhizomes above ground may be potted in fibrous peat and a little leaf-mould, pegging the rhizomes down on the soil. Some of the Davallias, Polypodiums, Pellæas, Pleopeltis, and others grow well on pieces of stumps of Tree Ferns, affixing themselves there-to like Orchids. If the stumps are in the vicinity of other Ferns, spores of different species are sure to vegetate in their crevices, more particularly those of Adiantums, Gymnogrammas, Aspleniums, and Pterises. Syringing Ferns is an operation requiring skill and care;

although some genera are partial to such treatment, others are particularly averse to it, more especially the Adiantams, Gymnogrammos, Cheilanthes, and other delicate and farinose kinds. Filmy Ferns are best grown in glass cases or under hand-lights or bell-glasses, or a division of the Fernery may be specially set apart for their culture. Most of the small delicate species thrive well on blocks of decaying wood, pieces of the Tree Fern stumps, or in pots; whilst for strong-growing kinds, like the Todeas, pot culture is the best and most convenient. For pot culture fibrous peat, chopped Sphagnum, and some fine sandstone chips make a good compost, and for Todeas the surface may be mulched with live Sphagnum. The smaller kinds of Ferns thrive well on little mounds composed of fibrous peat and sandstone chips, or on a block of wood embedded in turfy peat from which they can emerge and scramble over the wood. These Ferns like a steady moist atmosphere, but too much artificial heat is detrimental to them; in fact, a greenhouse temperature is almost sufficient for the whole of them. In watering let the water fall lightly upon the fronds, but in addition to these slight sprinklings water must also be given to the roots, more especially during the growing season. Hanging baskets should now be replenished with Ferns and Selaginellas, and Wardian cases should be examined and re-filled if necessary.

Flower Garden.

Spring flowers are now daily becoming so plentiful that herbaceous and shrubbery borders are getting quite attractive; on lawns, too, are tufts of Crocuses, Snowdrops, Dog's-tooth Violets, and other favourite bulbous plants that annually spring up and unfold their beauties when once planted in such positions. Under the wide-spreading canopy of large deciduous trees a spring carpet of white, yellow, and blue, furnished by early-blooming bulbs, is most desirable and pleasing, and in such a situation they thrive where not a vestige of Grass will grow. Only the commoner kinds, however, should be used in that manner, for the finer ones, if so treated, are apt to degenerate; hence the necessity of a good position for them, where they can retain their foliage until the bulbs are properly matured, when the foliage may be cut over and the surface of the ground carpeted with annuals or other shallow-rooting plants. Lawns should be swept, rolled, and, if necessary, mowed. Where they are covered with Moss it should be raked off, a top-dressing of finely-sifted soil applied, and some Grass and White Clover seeds sown at the same time. The top-dressing should be equally spread, raked smoothly and level, and then well rolled. Should the lawn be thinly covered with Grass, although free from Moss, a top-dressing of good soil, with some guano mixed with it, and also a sprinkling of Grass and Clover seed, will greatly renovate the turf. Before applying it, however, go over the surface with an iron-toothed rake, so that the old and new soils may the more readily unite; soot, salt, or guano applied alone in rainy weather is also productive of excellent results. If the edges of lawns or Grass walks be well rolled before trimming them, that operation can be more neatly and accurately done. Turfing of lawns may still be performed, but the sooner such work is finished now the better will the Grass stand the summer's drought. In the absence of turf seeds may be used, but in that case a long time elapses before a thick, close carpet can be formed, and continuous attention in the way of mowing is requisite. Alterations in the flower garden or pleasure grounds may still be proceeded with. The planting of deciduous trees cannot, however, be too speedily finished now for a season; evergreens may be transplanted later. Coniferous trees, as a rule, transplant very well in the spring time. In planting, preserve the roots as entire as possible, and do not bury them more deeply than is necessary; stake such as require support. Instead of roughly filling in the soil, it should be well and carefully worked in amongst the roots with the hand, and a good soaking of water at planting time has also an excellent effect in settling the soil about the roots.

Vegetables.

Make another sowing of Peas. Where suitable sticks are plentiful, tall kinds are the best to sow at this period of the year, as they bear longer than dwarf sorts, or such as are of medium height. Where tall varieties are grown, always give plenty of room; there should be not less than 5 ft. between the rows, as to crowd them is the reverse of any gain, for without sufficient air and light the pods never fill as they ought. Directly the earliest sowings are staked, a line of Spinach should be sown between the rows. This will be ready for use and the ground cleared before the Peas are fit to gather, and it will in no way interfere with their growth. The main crop, Onions, should be sown as soon as the land is sufficiently dry, but on no account if it be so wet as to adhere to either the tools or the feet, as should the seed be sown when the soil is at all sticky, subsequent dry weather will be sure to bake it so hard as to prevent its working well through the ensuing season. In pointing in the surface-dressing of manure spread over the ground do not let it be too deep, or the young plants will be too long in getting their roots into it. Many of the north country Onion growers put the greater portion of the manure they use on the surface, allowing it to remain until it is well sweetened by the action of the air, sowing the seeds in it, and covering the whole with ½ in. of soil from the alleys. With this, as with almost all other vegetables, the system of growing in rows should be recommended. It must be admitted that it takes a considerable time longer in sowing than the broadcast plan, but it affords such great facilities for thinning the crops, for the use of the hoe is destroying weeds, and for keeping the surface stirred (by which the ground is aërated and made open for the descent of rains, and the loss of moisture by evaporation in dry weather is prevented), that the first trouble is amply compensated for by the succeeding results. The use of soot should not be omitted, especially in old gardens where the land is at all light, for in these the ravages of the Onion grub are most feft; the soot not only acts as a powerful manure, but the ground retains the smell through the season in a way that is so objectionable to the fly as to have a considerable influence in preventing it depositing its eggs on a crop where the land has been dressed with it. After the ground has been levelled, tread the whole quite solid. The lighter the land is naturally, the more solid it ought to be made. Then mark out the rows 1 ft. apart and ½ in. deep. After sowing, draw the soil over the seeds with the back of the rake. Tread the ground thoroughly, and finish by rolling. In dry districts, where Broad Beans were sown about the beginning of the year, they will be now above the ground, and a second sowing should be made; this crop also likes heavy soil. Sow more Radishes, raking in the seed, it not being necessary now to cover it with litter. See that the litter is removed altogether from the second sowings as soon as up, for after this time the frost is not likely to be sufficiently severe to injure them. Sow a little Mustard and Cress every fortnight in well-manured ground. To have this young and tender it is necessary to sow often. Lettuce should also be sown on the richest piece of ground available—a little of the Cabbage variety (Tom Thumb) as well as Cos; the former will be sooner fit for use and precede the erect-growing kinds. Rows for the latter should be 15 in. apart; the others will do a third less. In sowing, the best method is to drop the seeds, half-a-dozen together, in patches as required to be grown; afterward thin them out to a single plant. If the weather be mild, a portion of those that have been wintered in frames should be planted out in a sunny, sheltered position; but do not risk the whole, as I have known the weather after this time to be so severe as to seriously affect them, especially after a winter like the present, when every kind of vegetation has been kept continuously soft and growing. Take them up carefully with a trowel, so as to preserve the roots as far as possible from injury. Give some water as soon as planted, and if the days be sunny or the nights cold, place a small flower-pot over each plant for a few days, but not pressed down so closely as to exclude the light.

Little Rock Gardens.—In small gardens or elsewhere, where there is no scope for the creation of picturesque scenery without offending correct taste in such matters, a little rockery of alpine or other plants similar to the one shown in our illustration, will always prove a source of pleasure if properly tended. A rockery on a small scale may be created, in every way suited for the cultivation of what are termed alpine plants, by raising mounds of good soil and partly covering the surface with stones, vitrified bricks, or clinkers. The largest pieces may be partially bedded in the soil. When the stones, or whatever materials used, are satisfactorily arranged, the cavities between them should be filled up with good soil to suit the different plants. Equal parts of loam and peat will suit most of them, but for some species a larger proportion of peat should be used, and fragments of stone or gritty matter should be mixed with it to keep the soil open and to secure efficient drainage. When the mound or bed has had time to settle, the planting may be commenced, and it is now that some knowledge of the antecedents and habits of the different species is desirable, in order to select proper and suitable sites, to give the small, delicate species a sheltered nook on the lee side of some large stone, and to plant the strong grower near the base of the work, where it cannot overhang and smother up its weaker neighbour. There are some kinds that delight to grow on a rocky ledge and overhang its outward face. Some love shade, and may be planted where some shelter from the sun's hottest rays can be had; others, again, love sunshine, and will revel in its fiercest beams. After all that may or can

A little Rockery.

be written or said on this subject, there is no royal road to the acquisition of this or any other kind of special knowledge, and there is no better way of becoming actually acquainted with alpine plants and the best mode of cultivating them than by commencing with a small collection, and as one's knowledge and interest increases to keep adding to it; and as beds or mounds of alpine plants need not assume any geometrical plan, we can add a bed or two any time we may think proper to do so. In this way we shall have time to become acquainted with all our favourites, to keep a close eye upon each, and if one looks unhappy to ascertain the cause and supply the remedy; indeed, the plant itself, if the symptoms are intelligently studied, will supply all the information we require to form a correct estimate of its condition. Planting alpines on raised beds or mounds is a much more interesting way of cultivating them than in the level border, even in the case of such kinds as succeed under ordinary border culture. In the first place they are brought nearer the eye; study is made more easy and interesting; and in the periodical digging and hoeing of borders many choice plants are often seriously injured from want of care. Then, again, in winter, it is the constant damp rather than the cold that injures the natives of the snow-clad regions, and on a well-drained mound of rockwork this source of danger would be mitigated or altogether removed.

Abutilon vexillarium.—I recently observed a remarkably fine specimen of this handsome greenhouse plant growing in a conservatory near Dorking. It was trained on the roof, from which hung down festoons of medium-sized bell-shaped flowers of a bright red and orange colour, and very effective at this season of the year. In the same conservatory, and also trained on the roof, was a beautiful plant of the seldom-seen Solanum jasminoides, furnished with beautiful white Jasmine-like flowers, that are very useful in winter in a cut state. They are produced in trusses in great profusion, and continue long in perfection. The back wall of this conservatory was covered with fine plants of some of the old varieties of Pelargoniums, noticeable amongst which was a fine specimen abundantly in flower of the very old kind called quercifolium floribundum; it bears blossoms of a lively shade of rosy-purple. This Pelargonium, though rarely

seen now, is a capital plant for covering walls or pillars in a conservatory.—B.

GLASSHOUSES AND FRAMES.

HOW TO STOCK A SMALL GREENHOUSE.

In the first place avoid the two great snares of the anxious "Amateur," namely: *over*-potting and *over*-crowding. As to pots, it may be accepted as a standard rule that no plants require anything beyond a 10-in. pot. Of course, here we are speaking of ordinary sized flowers, not the giant specimens of the florist or stovehouse. Nothing to our mind is more ugly than the rows of huge 12-in. and even larger pots to be seen in the greenhouses of so many amateurs, the specimens grown leggy or shrivelled up as the case may be. The great secret of a *pretty* greenhouse stage is to have your stage not higher than 3 ft. 6 in., so that one looks down *on the flowers*, in place of the pots, as so often happens by the stages being made awkwardly high. Take care not to exceed *more* than two specimens of a kind—of course, by this we mean identical in colour—arrange the taller specimens in the background, bringing the shorter plants to the front, with due regard to their habit. Carefully go over your plants quite every other day, picking off drying leaves and blooms, and have all swept up, so as to be trim and neat. Nothing spoils the effect of a greenhouse more than untidiness. After watering, put the can and other implements used carefully out of sight; these are never picturesque. With regard to over-potting, this is a folly which spoils many a house of really choice flowers. The great art in growing flowers in pots is to have them dwarf, full-foliaged, and finely bloomed. For this purpose a 6-in. pot is useful for all Geraniums and Fuchsias, and an 8-in., the largest at most that should be given to the greenhouse annuals, such as Primula, Cineraria, Calceolaria—all of which are very gross feeders and require extra pot-room to form roots for quick flowering. Of course, where flowers are grown in 6-in. pots they must be potted freshly every year, and then a strong, rich compost must be composed of loam, manure, and silver sand, and plenty of drainage given by a generous use of broken crocks. When watering, give your plants a strong solution of manure at least once a week. What, again, can be more ugly than the spindled-looking Geraniums and Fuchsias as grown too often by amateurs—a long brown stem, and perhaps crowned with a really fine bunch of blossom, which seems to mock the ugly stem from which it sprang with its drooping loveliness. To anyone reading this with such plants disfiguring his greenhouse we would say, cut the plant down with what you may feel is a ruthless hand and plant the cuttings. We will venture to promise nine out of every ten will strike; also that in all likelihood the old plant repotted and put in gentle heat will delight you by bursting out in fresh beauty In order to keep Fuchsias bushy the extreme points of the young shoots must be kept pinched out; for every such pinch you will have four or five more shoots. Another mistake the amateur is liable to make is that of stocking his home with plants which are unsuitable and difficult of culture, and thereby crowding is ensured and green fly engendered.

The following is a list of the best flowers for a small unheated greenhouse, all of which may be attempted without the assistance of a gardener, and with no other appliances except that of an ordinary frame and hotbed. The list of flowers given are selected for three reasons—first, almost perpetual blooming; second, freedom from green fly; third, hardiness of growth. Geraniums in variety, Fuchsias in variety, Petunias, Daphne indica rubra, very sweet-scented; Heliotropes, tuberous Begonias, Achimenes, Musk, Cyclamen, Mesembryanthemum, Lantanas, Tree Carnations, Azaleas, Camellias, Balsams, Lilium lancifolium, Cactus, Mimmulus, Hyacinths, Christmas Roses, Tulips, Primulas, Calceolarias, and Cineraria.

For hanging baskets nothing can be prettier than the glossy Ivy-leaf Geraniums, variegated Mesembryanthemums, or the fresh, lovely Nemophila insignis and the Tradescantia; and where fragrance is sought after, nothing can equal a pot or two of Mignonette—this is so easily managed, it is a wonder more is not grown; and the little bright Lobelia can be had in blossom all the year round. Loadstone.

Solanums or Winter Cherries.—These are the best of winter berry-bearing plants; they are easy of culture and are highly ornamental in windows or greenhouses when well furnished with bright scarlet fruit. About Christmas-time there is a ready sale for these in the London markets, and, indeed, throughout the whole of the winter there is a large demand for them. Market growers possess several varieties of them, but none are greater favourites than Weatherill's Hybrid, which is dwarf in habit, and produces masses of large bright scarlet berries. Some plant out their young plants in the open ground and pot them in autumn, but the most successful way is that of striking them in spring from cuttings which are obtained from old plants introduced into heat early in the year. The cuttings are inserted ten or twelve together in 5-in. or 6-in. pots, and are plunged in bottom-heat, in which they soon form roots; they are then potted singly in 3-in. pots, and, after having become well established, their shoots are stopped, which induces them to break and form bushy little plants. They are next shifted into 5-in. and 6-in. pots into good holding loam and sand. They are then arranged on wide, airy stages, on which they are allowed

The Solanum or Winter Cherry.

plenty of room, in order to induce them to grow short-jointed—a condition in which they yield more berries than they otherwise would. Thus circumstanced, they remain until their fruit is set, a free circulation of air being afforded them whilst they are in blossom. When the berries are fairly formed manure water is given them, which imparts to the leaves a healthy, deep green appearance, and helps the berries to swell. At this stage the plants are placed out-of-doors in the sunniest position that can be found for them; here the berries soon colour, and when that occurs the plants are taken to market. Late batches are finished off in houses in a moderately warm temperature.

AN UGLY BANK MADE BEAUTIFUL.

I know a bank than which nothing could be uglier when first I saw it. The aspect is good towards the south and west, and it is sheltered on the north by trees and a wall; but the soil was a horrid yellow gritty stuff, banked up against the wall and supported in front by a couple of rows of large stones. It did not look as if anything could grow in it, However, we were looking about for a suitable place where we could make a rockery, and decided to try it here. We concluded that we had only to get some good stones, to be roughly laid on, and cover the yellow bricky stuff with good vegetable mould, and then plant Alpines. We set to work accordingly. I shall not try to remember how many pretty Alpines perished on that bank. In vain we made holes in the clay and crammed in leaf mould; our Auriculas alternately damped off and burnt up. The slugs ate our choice Sedums, and anything else that had vegetation enough to be good eating. Our Cyclamens gave an occasional leaf, but never a flower. London Pride certainly did flower, and very pretty it was, but the green rosettes soon frizzled up and looked ugly. We encouraged one another, however, and persevered, and now the bank is really pretty. One thing which succeeded on it was the Muhlenbeckia complexa. I am sorry that I know no English name for it, and I have never seen it in flower. It has numerous small round dark green leaves, set on long wiry dark brown stems. It has often attracted attention, but whenever I have been asked for a root I have always warned the receiver that it bears a bad character. One of the gardeners at the Dublin College Botanic Gardens told me that it was a bad weed and would spoil any rockery that it got into. I cannot say that it showed any very overbearing disposition on the front of our bank; and I am almost afraid the last two winters have been too much for it. Last summer it hardly recovered the effects of the previous winter, and now it looks dead. But it ought to be evergreen. I am sorry if we have lost it, for it looked very pretty hanging over the stones which held up our bank. Its sprays are not unlike the fronds of the common Spleenwort. We had it from Cornwall. A common Sedum (Sedum spurium) has taken a liking to the place, and allows no more ugly yellow soil to be visible where it can come. It has run over the spot where we had planted a fine clump of Apennine Anemone, which, just contrives to send up a flower or two through it, and it would quite swallow up the little Campanula pusilla if I did not interfere and push it aside. But I like it. It looks green and vigorous with a pretty tipping of russet. I believe it would hide any ugliness in any spot where the sun shines, and it would keep weeds down. But another good thing on our bank is the vigorous growing Japan Anemone, the red sort. The foliage of this plant is good, and comes up early, though the flowers are late; and there is something particularly picturesque and good in the style of the flower-stems, buds, and blossoms. It is a plant which gains much by being allowed a good deal of space, and as it will really grow anywhere it is most valuable for filling and hiding ugly corners and banks. Slugs do not eat it; not even a bit of ground need, therefore, be entirely ugly and bare. Something can always be found which will cover any corner, and cover it with beauty, too, for those who have eyes to see the beauty which is neither new nor rare. We soon found that it would be impossible to grow anything very choice or tender on our bank without entirely remaking it, and that was not worth while so near the gate, and subject to the depredations of idle boys. But the bank is no longer an eyesore. Common hardy plants have made it interesting and pretty.—H.

ORNAMENTAL GOURDS.

The cultivation of the Gourd family in our flower gardens has hitherto been strangely neglected, and our object now is, by a description of a few of the most remarkable species, to direct more general attention to it. On the Continent Gourds have been long esteemed, either for their singularity or the handsome colouring of their fruits. Being climbing plants, they are employed for covering arbours, trellises, &c., and although most of them are annuals, the peculiar effect which they produce will repay the small trouble of an annual sowing. The subject of our illustration, the Gooseberry Gourd (C. grossularioides) is one of the handsomest of the family. It forms creeping stems about 8 ft. long, and of the thickness of a goose-quill. The fruit, which are produced in great abundance, are as large as a good-sized Gooseberry, and are finely marked with alternate longitudinal bands of very dark and very light green. They are so bitter in taste as to be inedible, and so numerous that a single plant will often bear from 500 to 800 fruit. Although the plant is a native of North Africa and Arabia, it can be advantageously grown in the open air in this country during the summer, and may either be sown, in the place where it is intended to remain, about the middle of May, or, in a hot-bed under a frame, in March or April, and afterwards transplanted, with a good

ball, into a bed of spent hot-bed material, or into a hole filled with stable manure, covered with some inches of soil. Although not absolutely necessary, frequent waterings during the heats of summer will be found useful in encouraging a vigorous growth. Another very singular species is C. metuliferous, which grows about 4 ft. or 5 ft. high, and bears largish egg-shaped irregularly-nibbed fruit, 4 in. to 6 in. long, studded with huge prominent spikes, and of a fine scarlet colour when ripe.

Enough, perhaps, has been stated to show the wonderful variety which exists amongst the fruits of this family of plants, and we shall conclude with the following enumeration of some species now in cultivation which present a most extraordinary diversity in the shape and colouring of their fruit, and seeds of which are easily procurable through any of our leading nurserymen. Amongst the finest of the larger fruited sorts are the Turk's Cap varieties, such as Grand Mogul, Pasha of Egypt, Viceroy, Empress, Bishop's Hat, &c., the Serpent Gourd, Gorilla, St. Aignan, Mons. Fould, Siphon, Half-moon, Giant's Punch-bowl, and the Mammoth, which weighs from 170 pounds to upwards of 200 pounds; while, among the miniature varieties, the Fig, Cricket-ball, Thumb, Cherry, Striped Custard, Hen's-egg, Pear, Bottle, Orange, Plover's-egg, &c., are most interesting kinds, and particularly useful for filling vases, &c. All these, as well as many others, grow well in our climate in summer, and do not require the protection of glass or any other shelter. The directions given for the culture of the Gooseberry Gourd will be found applicable to all the rest; those that are sown in frames early in the season being gradually hardened off by a judicious admission of air before they are finally planted out. This course, however, need only be pursued when an early growth is desired. The plants, as a rule, are tenacious of life, and will exist with a scanty supply of water and in indifferent soil; but if it is desired to grow them to their highest degree of perfection, they will, like their congeners the Melons and the Cucumbers, be found not insensible to the advantages of a rich and mellow compost and a liberal allowance of water at all times. These conditions are, in fact, essential to the abundant production of well-developed, finely shaped, and richly-coloured fruit.

POULTRY.

Light Brahmas.—The light Brahmas are now one of the most popular varieties of poultry. It is astounding what immense strides these birds have made within the last few years. We remember the time when they had to find a place in the variety class, as so few of them were bred. Now they are often the largest classes in a show, and we have seen as many as eighty pens in a single class at the Crystal Palace. This great popularity, exceeding, as it does, that of our old English game fowl and the Dorking, with all their years of careful breeding and selection, will be to those unacquainted with the properties of the Brahma somewhat surprising. It may, therefore, be useful to those who know little about the different varieties of poultry if I briefly describe the characteristics and properties of the Brahma. First, there is hardly any variety, except the Cochin, which are able to withstand the variations of our climate so well as the Brahma. For winter laying, at the time of the year when fresh eggs are very scarce, no matter how severe the winter may be, Brahmas lay very freely. We have had eggs in abundance since just before Christmas, and our pullets were not hatched until the middle of last May, and they are now laying capitally. Many times we have had to sweep the snow away before throwing the food to the birds, and often they could be seen walking through the snow hock-deep to seek a little shelter from the cold winds, under a shrub, perhaps only to return to their house as the time approached for them to lay an egg. Nature—or shall we say man, by his careful selection in breeding?—has provided them with such an abundance of feathers, that, however cold the weather may be, it does not seem to affect them much. The Cochin is an idle bird, seldom caring to seek for its food. The Brahma is quite different, and will roam over a field or through a garden as diligently hunting after grubs and insects as a game bird; or they will rest quite as well contented and happy confined in small space or a backyard as if they had the run of a large meadow or a freshly-ploughed field. It is owing to their hardiness, their good laying properties, their contented disposition, and their handsome appearance which has within a few years raised them to their present position as the favourites amongst all the many varieties of our domestic poultry.—CHANTICLEER.

1532.—**Houdan Eggs.**—In reply to "Foots Cray," I can testify to the excellent qualities possessed by Houdan hens, having kept them for three years. The chickens feather and grow quickly, are hardy and easily reared. They are splendid layers of larged sized eggs, and, excepting Brahmas and Cochins, are not surpassed for strength of constitution and general stamina by any other breed.—SKERNE, *Wansford, Hull.*

Eggs for Hatching.—Will some one kindly inform me how long eggs may be safely kept for hatching?—C. E. S.

The Gooseberry Gourd.

Gapes in Chickens.—Can any one kindly tell me a cure for this disease, which attacks them when about six weeks old? I have tried everything I know, but without success.—J. R.

Ducks.—Will any one kindly tell me what is the best breed to keep where there is no water, for laying and for table use; what food should they have, and how often? I prefer the Aylesbury or any large sort. Any other information will be acceptable.—W. G.

White Brahma Fowls.—Will any reader kindly tell me where and at what price I can obtain a few eggs of thorough-bred white Brahmas for sitting, and also the best time to hatch them for laying in winter?—NOVICE.

Eggs Without Shells.—Your correspondent E. J. C. (page 794) complains of eggs having very thin shells, and dropping from the hens at night. I have effectually cured all that, and in a very simple way too. I merely keep all my broken crockery-ware instead of letting the servants pitch it into dustbins, &c. I then smash it up every other day into small pieces about the size of Peas; it is easily done with an axe or hammer; and the hens eat the broken crockery with avidity and the silica contained therein makes my eggs very hard indeed.—C. W. MILNE, *Secly Park.*

Fowls not Laying.—"W. H. S." complains that his pullets do not lay. I should think their time is fully employed in discussing their four or five meals a day without troubling themselves about laying. I should recommend him to try feeding them twice a day; in the morning give them Barley-meal or ground Oats made very stiff; and about one or two o'clock give them whole Barley or Maize, or some other kind of corn. Always give them as much green food and garden refuse as possible, and never give them more food than they can eat, as it only gets wasted by being trodden into the ground. A small tea-spoonfull of cayenne one or twice a week in their meal will perhaps have the desired effect.—W. T. D.

ANSWERS TO QUERIES.

1369.—**Annuals for Exhibition.**—The criticism of my selection of annuals for exhibition in reply to the query as above made by "Weston-super-Mare" necessitates some notice on my part. Antirrhinums are just as much hardy annuals in this locality as dozens of other recognised annuals. We sow in February under glass, get a crop of flowers and seed in the autumn, and the winters kill nearly all of the plants. Grown under such conditions, it is entirely annual in habit. The introduction of Mimulus applied only to the comparatively annual Mimulus maculosus or spotted kinds, so well represented by Clapham's strain. Raised from seed, also sown in February, and flowering through the summer, they too are killed in the winter. To convert such things, that seed so freely and are so easily propapated by seed, into perennials would be absurd. The calling this Mimulus moschatus was a mistake. Ageratums, Petunias, and Lobelias, although if kept in heat through the winter and propagated by cuttings practically become soft-wooded perennials, are in the open air but annuals; and all can be and are freely raised from seed. Here both the latter, raised from seed each spring, are grown as tender annuals for seed production, and are in every sense just as much annuals as are Stocks or

Asters. In recommending annuals for exhibition much depends upon the nature of the question. In this case there was no indication whether the plants were for pot culture or to be exhibited as cut flowers; but it was accepted that the plants were to be sown in pots; hence the selection. The time of year should also be named at which the things are needed to be in bloom, as selections might be given of plants that are naturally flowering in early summer and late autumn. Some of the plants mentioned by my critic are late and difficult of culture, especially to amateurs—Celosias, for instance, needing considerable heat to produce them in good condition. Our desire is to answer all queries as nearly as possible in accordance with the requirements of the questioner.—A., *Middlesex*.

1532.—**Annuals and Perennials for Bouquets.**—*Hardy annuals*—Chrysanthemum Dunnetl pleno, white; Lathyrus azureus, sky blue; Mignonette, white; Nicotiana suaveolens, white; Sweet Pea, various; and Scabiosa candidissima pleno, white. *Half-hardy annuals*—Acroclinum roseum, rose; Aster Pæony and Chrysanthemum-flowered, various; Dianthus imperialis fl.-pl., Heddewigi fl.-pl., and laciniata fl.-pl., various; Helichrysum compositum, various; Phlox Drummondi, various; Rhodanthe atrosanguinea, magenta; Statice sinuata atrocœrulea, blue; Sultan (Sweet), white; Zinnia elegans and elegans fl.-pl., various. *Hardy perennials*—Achillea Ptarmica fl.-pl., white; Agapanthus umbellatus, blue; Alstrœmeria aurea, orange; Amaryllis Belladonna, rose; Ammobium alatum, white; Anthericum Liliastrum, white; Anemone japonica Honorine Jobert, white; Campanula persicifolia pleno (blue) and alba, white; Catananche alba fl.-pl. (white) and cœrulea, blue; Chrysanthemum chinensis, varieties; Colchicum autumnale alba fl.-pl., white; Convallaria majalis, white; Dianthus hybridus Marie Paré (white) and multiflorus, red; Dianthus caryophyllus fl.-pl. (Carnation) varieties; Dielytra eximea, red; Francoa appendiculata alba, white; Galanthus plicatus (Giant Snowdrop), white; Geum coccineum, scarlet; Helleborus niger (Christmas Rose), white; Iris persica, blue and white; Iris reticulata, violet and yellow; Lathyrus grandiflorus (red) and albus, white; Leucojum vernum, white; Myosotis dissitiflora, blue; Narcissus poeticus fl.-pl., white; Omphalodes verna (blue) and verna alba, white; Phlox decussata, varieties; Pyrethrum, double varieties; Ranunculus aconitifolius fl.-pl., white; Saxifraga granulata fl.-pl., white; Schizostylis coccinea, scarlet; Scilla nivalis, blue; Sisyrinchum grandiflorum, purple; Spiræa japonica, white; Statice latifolia, blue; Viola odorata Victoria Regina, violet; and Thalictrum adiantifolium, a good substitute for Maiden-hair Fern.—WESTON-SUPER-MARE.

1518.—**Hotbed Frames.**—I constructed a small hotbed as follows:—I bought a champagne case from the wine merchant's, cost 4d.; a Yorkshire pudding pan from the ironmonger's, 19 in. by 12½ in., cost 1s. 9d.; a sheet of tin 20 in. by 14 in., cost 6d. I had the tin soldered on to the top of the pan at a cost of 6d., with a small pipe attached for filling. This made me a shallow boiler, with a large heating surface. I knocked the top and bottom off the case, and fixed the pan to the bottom; I then elevated the box on two flower-pots on the floor of the greenhouse, and put underneath a benzoline lamp, which cost 1s., and covered the top with a sheet of glass, which cost only 5½d. I then filled the pan with hot water, corked the filling pipe, half filled the box with Cocoa-nut fibre, and lit the lamp. In twenty-four hours I filled the frame with cuttings in pots, and they appear to be doing well. I get a continuous bottom-heat of from 70° to 80°. The cost of the whole was 4s. 6½d., and I find that a pint of benzoline will last ninety-six hours. The lamp requires filling every twenty-four hours. The inside measure of the box is 21½ in. by 13½ in.—G. A.

1518.—**How to Make a Hotbed Frame.**—The most useful frames are those with two or three lights. The best size for them is as follows:—4 ft. wide, 8 ft. to 10 ft. long, and 15 in. to 20 in. in depth at the back, and 7 in. to 10 in. in the front. The wood should consist of well-planed deal, and the frame should be dovetailed together at the joints; the top should be tied together by two crosspieces 3 in. wide, which should be dovetailed one end into the back and the other into the front, and so placed that they will come exactly under where the lights meet each other. These crosspieces should have a kind of trench on the upper side, so as to draw off all the water from between the lights. At each end of the frames there should be a piece of wood ¾ in. thick and about 4 in. broad nailed on so as the upper edge will be level with the upper surface of light. The use of this is to exclude the cold winds which are apt to blow under the lights. The lights should be 4 ft. and 3 ft. 4 in. wide, and glazed with a strong 16 oz. sheet glass, which costs at the rate of twopence or threepence per square foot. The laps should not be puttied, but left open so as to admit the condensed moisture to escape. When complete the frame should be painted white inside and dark lead outside. Do not adopt the use of glue, as the damp and wet is sure to part it.—IGNORANT.

1536.—**Birds and Seeds.**—This appears a seasonable question, as the time for general sowing in the open ground draws near. Instead of dressing the seeds with any preparation, I would recommend sprinkling freshly-slaked lime over the seed-bed immediately after sowing—not a thick coating, but just enough to give the bed a white appearance. This the birds seem to dislike, and they will not alight on the white surface. The cost of such lime is trifling, and it only needs renewal in case of heavy rains washing all the lime into the soil; moreover, no soil will be injured by such an application, and all old garden soil will be improved thereby. Another plan is to drive several short pegs into the ground, around the sides of the bed, and to run white cotton across the bed from peg to peg at a few inches from the surface. This is rather more troublesome than the former plan, but it has the advantage of not requiring any renewal, and it generally keeps birds off the seed-bed, probably because they think it is some kind of trap. The first method I have never known to fail, and the second has failed with me only very seldom. For those not familiar with the article, it may be mentioned that fresh lime for gardening purposes should be kept, in some vessel as nearly air-tight as possible, in some cool place under cover.—C. L. J.

1590.—**Heating Small Greenhouses.**—I am about to erect a small greenhouse (10 ft. long), and should be glad to know the best and cheapest way of heating it by gas. Also has any reader tried Bateman's metal fires for this purpose?—J. C.

1503.—**Treatment of Dracænas.**—"H. M." may find the following useful for treating his plants. Take a thumb-pot, and roll the leaves up so as to put them through the hole at the bottom of the pot; or a pot may be broken in halves, and tied together after putting round the stem. The pot should be placed close under the remaining leaves on the stem; then fill the pot with Moss, and in a short time the stem will root. When the stem has a good root cut it off close to the bottom of the pot; in a short time a good table plant will be the result. The old stump will break again and make as good a plant as before. The Moss in the pot must not be kept too wet. The spring is the best time for the operation.—H. B.

1501.—**Steam in Forcing Frame.**—I beg to inform your correspondent that the excess of moisture of which he complains is caused by his burning the lamp with too large a flame. Ventilating the frame by tilting upwards the sash at the back, or by sliding it sideways, will enable him to remedy his difficulty should he again use too much heat. Should he be unable to regulate the temperature of the house in which is situated the frame, the lamp may with advantage be extinguished for five or six hours in the middle of a warm day.—A. WOODROFFE.

1473.—**Solanum or Winter Cherry.**—I successfully grew a large quantity of plants of S. capsicastrum last year, and have wintered between five and six dozen plants. I have cut back some to form bushy plants, and others I have trained for standards. I have a few with berries upon them of a large size. Those plants which I cut back about three weeks ago are breaking again very nicely, and all are and have been for all throughout the winter in very healthy condition. I keep them in a greenhouse and liberally supply them with water, the want of which, I have little doubt, has caused "H. B.'s" plants to drop their leaves. I would advise him to cut back his plants at once and plant them out-of-doors in a sunny situation when all danger of frosts are past, when if he sees they do not lack water, they will flower and berry there, and he can take them up again in September handsome plants for next winter's decoration.—J. L.

1524.—**Flower Seeds for Unheated House.**—Almost all kind of tender annuals may be raised without heat under glass, if sown in the months of March or April, as the sun is then powerful enough to germinate seeds freely. Such things as Cockscombs, Celosias, and Balsams make capital greenhouse pot plants; so also do Petunias, Mignonette, Stocks, and even Asters, if the latter are planted out into the open ground in May and lifted into pots just when coming into bloom. The dwarf double Larkspurs, Portulaccas, Godetia Lady Albemarle, Tagetes signata pumila, Phlox Drummondi, with a few ornamental Grasses, such as Brisa maxima, Agrostis nebulosa, Isolepsis gracilis, &c—these, if well grown, will serve to make a cool greenhouse very gay all through the summer and autumn.—A.

1567.—**Worms in Gardens.**—As a rule, worms do a beneficial work in gardens; they thoroughly aerate the soil, and considerably decompose it by passing much of it through their bodies. All worm-casts seen on lawns have been so digested and then exuded. Where so very abundant, however, they become a nuisance, and free dressings of fresh-slaked lime will destroy them wholesale, as also will dry, clean soot. The lime should, not be dressed too thickly; it is the minute particles of dust, so full of irritation, that, falling upon the worms, causes them to retire. Such dressings need to be frequently applied, and in the end will soon get rid of them. These dressing will do no harm to plants or Grass; even coarse salt may be used with great advantage on footpaths and amongst vegetables—of course sparingly.—A. D.

1563.—**Manure for Potatoes.**—Potatoes need a manure that is quick of action, and calculated to supply the special need of phosphates, as without these the quality of the tubers will be poor. Good guano or superphosphate guano are good artificial manures; wood ashes supply phosphates, but lack ammonia and other important compounds. With really good stable manure scarcely any other kind of dressing is needed, as it is not possible for the plants to take up more than a certain amount of nutriment. Artificial manures are most valuable when employed with Potatoes that succeed some other crop which has been previously manured. Dissolved bones make a good permanent manure, but it is hardly active enough for Potatoes. It would be invidious to name any special manure where so many are good; but last year we found one manufactured at Deptford to be the best for Potatoes we have ever employed.—A. D.

1504.—**Double Pyrethrums and Potentillas.**—Both double Pyrethrums and Potentillas would mix admirably with Pentstemons and Delphiniums, the latter being kept into the centre and the Pyrethrums next. Such perennials as those stated would help to make a striking bed for a long time, and might be added to with some of the best perennial Phloxes, as these present some of the grandest of border plants. A few Liliums of various kinds would intermix well. The soil of such bed should be trenched 30 in. deep, and be well manured before planting.—A. D.

1505.—**Tritelia uniflora.**—Bulbs of this plant that are mouldy are, no doubt, practically dead. Perhaps they have been too long exposed to air and have lost generative power. The best place for them is in the ground, as they will come up in the open ground from year to year as freely as will Snowdrops and Crocuses.—D.

1506.—**Apple Stocks.**—Apple stocks raised from the seed or pips of the best fruits are, as a rule, little better than Crab Apples, although just a few may in time produce fruit, but these will show fruit much sooner if grafted on to other stocks, as all Apples are. The stocks would make the foundation for good trees if they were cut back to within 6 in. of the ground about the end of March, and all grafted with scions from good sorts of Apple trees. In three years they would probably begin to produce fruit, and would fast grow into value. Without being grafted the stocks are little better than weeds.—D.

1567.—**Worms in Gardens.**—Hot lime will have the effect of getting the worms out of the ground. It should be used at the rate of 1 lb. to the gallon of water. Give the ground or Grass a good soaking with the liquid, when the worms will come out in numbers. They must be gathered and destroyed.—J. S.

1562.—**Flowers for Bouquets in June.**—Few flowers make up better for coat flowers than those of Phlox Drummondi. Obtain a good packet of seed, sow at once in a greenhouse. Bottom-heat is not requisite. When large enough to handle fill a quantity of 6-in. pots with a mixture of loam, leaf-mould, rotten manure in equal proportions, adding a good sprinkle of sand; then put five of the seedlings into each pot. A slight fumigating will be required, they being a little subject to green fly. By so doing you will not fail to produce a brilliant display of bloom by June next. A few plants of the Maiden-hair Fern would supply you with a background to make your button-holes upon.—J. S.

1569.—**Cropping a River Bank.**—Parsnips would do well upon such soil. Sow at once the Hollow-crowned variety. You may try the Long Surrey Carrot at the top of the bank. I should recommend Champion Potatoes for such a situation.—J. S.

1569.—**Cropping a River Bank.**—The best kind of Potatoes to grow on a river bank where the soil is heavy are Champion and Magnum Bonum—to plant others may result in disease and failure. Parsnips would do very well, but Carrots need a light, deep soil. Onions, Broad-Beans, and Runner Beans may do very well in such soil, as they prefer it rich and holding. Winter Greens, such as Savoy Cabbages, Scotch and Cottagers' Kale, and Sprouting Broccoli, may be planted to succeed any early crops.—A. D.

1579.—**Variegated Mesembryanthemum from Cuttings.**—Cuttings of the variegated Mesembryanthemum should be permitted to lie for a few hours after being taken off before being inserted in the cutting pots. A free warmth promotes quick rooting, and damp does no harm; the chief danger lies in heat that is too moderate, and does not induce rapid rooting and growth. The soil in which the cuttings are put should be composed largely of sharp silver sand. Shallow pans should be used, and the cuttings not too thickly inserted.—A.

1588.—**The Chimney Campanula** (C. pyramidalis).—Campanula pyramidalis is a fine plant for pot culture, but ofttimes in the open air it does only indifferently well. The side shoots should be taken off if possible with a small portion of root attached, potted out singly in small pots, and when large enough re-potted into 9-in. pots in which to bloom. These plants should have the protection of a cold frame through the winter to keep the leading crown from injury by frost. Grown liberally in good sized pots such plants should flower finely.—D.

1573.—**Pelargoniums Failing.**—Your Pelargoniums have been wrongly treated. They should have been cut down after blooming and allowed to break well before being rmoved to smaller pots. I cannot understand your shifting them again at Christmas into larger pots, they not having broken into growth. The temperature has been quite sufficient. I would advise you to cut them down entirely and remove them into smaller pots, and try plunging in heat if convenient.—J. S.

1576.—**Camellias Failing.**—I am not surprised at your Camellias falling; the temperature submitted to them, as you say 50° to 55°, is too high for them at least by 10°. Take off all the shrivelled buds, and keep the plants in the temperature they are now in, and syringe them freely every day until they have made new growth. When finished growing, gradually harden them in a lower temperature, placing them out-of-doors in June, returning them to a cool house early in October.—J. S.

1525.—**Creepers for Low Walls.**—The spring blooming kinds of Clematis are most valuable decorative climbers for a north wall, as they practically bloom in summer in such a position, and for a longer period. The summer kinds really then bloom in autumn. Everlasting Peas are useful; and for blooming just now one of the best is Jasminium nudiflorum. For foliage the broad-leaved Aristolochia, Virginian Creeper, and variegated Ivies are good, but these latter prefer to climb the brickwork.—D.

1526.—**French Perennial Phlox.**—Although perennial Phloxes will seed at times freely, the seed does not germinate readily, and it is necessary to exercise considerable patience. Seed might be sown now in pots or pans in a frame or greenhouse, and be allowed to stand, only kept just moist, until the seed germinates. Seedlings should bloom next year if grown on in good rich garden soil, the plants needing only common garden culture.—A.

1527.—**Gladiolus Brenchleyensis.**—Single bulbs of Gladiolus Brenchleyensis will bloom well if grown in 7-in. pots; in a less size the spikes will be poor. The soil should be composed of good yellow loam, with one-third of well-rotted manure, and a sprinkling of silver sand in it. Bury the bulbs about 2 in. They may be potted at once, and kept under glass until all danger from frost is past. Weak manure water will be of use during the summer.—A. D.

1528.—**Hybridised Pelargoniums.**—Pelargonium seed of all kinds may be sown at once in a shallow pan. It is a good rule to dibble in the seeds with regularity all over the pan, leaving the long tail exposed. Fix the seed firmly, and water gently, keeping the pans shaded during strong sunshine. The seed should germinate within three weeks, but it is uncertain whether the plants will bloom the same season. Some may, others may not; probably the majority will bloom late in the autumn.—D.

QUERIES.

1605.—**Vitality of Seeds.**—I am informed that seeds kept over from last spring will not germinate. To what extent, if at all, is this true of flower and vegetable seeds?—H.

1606.—**Propagating Hyacinths.**—Is it possible to propagate Hyacinths and other Dutch bulbs in this country? If so, how is it done? and how long do they take to reach perfection?—H.

1607.—**Treatment of Rhododendrons.**—I have planted a number of Rhododendrons on the bank of a pond sloping to the north-west. The soil is heavy, and, not having any peat available, I put some coal ashes in with each plant. Was this right? and is there anything more that I can do? Is it well to dig the ground round the plants, or to lay it down in Grass? What about pruning? My shrubs are only about 4 ft. high, but are very scraggy, the only foliage being on the ends of the stems.—H.

1608.—**Potatoes.**—What weight of Potatoes am I to reckon (for seed) to the square yard? or how much ground will 1 lb. sow?—A. L. S.

1609.—**Camellia Losing its Leaves.**—I have a Camellia which stood close to a wall all the autumn, and appeared to be very healthy and growing well, and had several buds upon it. After it was taken into a sitting-room, just as the buds were breaking and the colour of the flower could be seen, they turned quite brown, and eventually fall off. The leaves all this time looked green and well until about a fortnight ago, when one by one they began to turn brown at the edges and dropped off: the plant is now almost bare. What can I do to prevent it dying off entirely?—J. W. G.

1610.—**Salting Vegetable Ground.**—Will some one give me a list of vegatables to which salt is beneficial and prejudicial? How much salt can I put on ground where Beet, Turnips, Cabbage, Broccoli, Onions, Carrots, Lettuces, &c., are to be grown? I am planting my Potatoes between my Cabbage plants, as I planted my Cabbage plants between my Potatoes. If I sow 2 tons of salt to the acre for the Potatoes will it kill the Cabbage plants as well as the slugs? For the other crops (not Potatoes) would it better to sow with the seed, or to dig the salt under and then sow the seed? How much for each vegetable?—T. C. V. B.

1611.—**Manuring Potatoes.**—In your issue of Feb. 21, "A. L.," in writing of seed Potatoes, and manuring the same, says that "for home consumption" good soil with a liberal dressing of manure may answer, but for all main crops manure should be avoided." May not this statement be qualified somewhat, as it puzzles an amateur who has never seen Potatoes planted without manure?—TUBER.

1612.—**Propagating Virginian Creepers.**—When is the best time to put in cuttings of Virginian Creepers? I want to cover by means of wirework an unsightly view. I also want the names of a few fine-foliaged plants, about 8 in. high, for border with south-east aspect.—DARCOM.

1613.—**Climbing Annuals for Summer.**—I wish to have a show of climbing annuals for next summer in a south aspect. Could any one name best varieties—stating time and mode of raising, treatment, &c.?—PARASITE.

1614.—**Floury Potatoes.**—The soil of my garden is a cold clay loam; can any one inform me what kind of Potato I ought to plant to get a good crop of floury and sound tubers?—SUBSCRIBER.

1615.—**Plants in Vineries.**—Many thanks to "H." for his answer in reference to this subject. Will he or someone else please to tell me what temperature by day, also by night, will be best for the Vines? Likewise air and ventilation, as the buds are beginning to break. They are Black Hamburgh and White Sweetwater planted outside in a border 3 ft. wide, which has not been covered up. The temperature inside has ranged from 35° to 40° by night, and from 45° to 50. by day, giving air top or side according to the weather.—W. L.

1616.—**Winter and Spring Flowering Plants.**—What plants flower best in winter and early spring in a greenhouse where the temperature is never much below 45° at night?—S. G. W.

1617.—**Manure for Pot Roses.**—What quantity of guano must I put to a gallon of water for watering pot Roses? also how often must it be given them? Will bones burned and then crushed answer the same as bone dust?—CONSTANT READER.

1618.—**Cropping Poor Land.**—I have a piece of land on which Wheat was grown last season; it was pretty well manured last autumn, but I find on digging it that one part is better than the other, the poorer part being badly infested with Coltsfoot. I wish to grow Potatoes, Cabbage, Peas, Beans, Onions, Carrots, Turnips, Parsnips, &c., and would like information as to which of the above would be best suited to the part in which the Coltsfoot abounds; and also how to get rid of the latter. I am told that manure will kill it. Is this so? Also what kinds of Potatoes can be recommended for such soil; it is a stiff clayey bottom. Situation high and open.—NOVICE.

1619.—**Making Hard Water Soft.**—Can any of your correspondents kindly advise as to the best method of rendering hard water soft, so that it may not be so injurious to plants, &c.?—T. F.

1620.—**Impressions of Fern Fronds.**—Can any one tell me how to take impressions of fronds on paper?—NEPTUNE.

1621.—**Sparrows Eating Lawn Seeds.**—Could any reader tell me of some plan for preventing sparrows, &c., from eating lawn seed? I have tried a scarecrow of string, paper, &c., but have not succeeded in frightening them away. The only other method I can think of is to raise a large net on poles over the ground, but this is costly and troublesome business. Last year the seeds were devoured wholesale as fast as I sowed them. I should like to know of a simpler and thoroughly efficacious preventive.—A LAWN LOVER.

1622.—**Renovating Holly Hedges.**—The Holly hedge surrounding my garden, although it was impossible to see through it in the summer of 1878, is now almost bare of leaves, especially under the forest trees which shade it here and there, owing in a great measure to the last two severe winters. Can I renovate it by any means?—HOLLY BANK.

1623.—**Roses for North Yorkshire.**—I have a square bed, one side of which is against a wall where there is some climbing Roses. I propose making a border of Grass, 2 ft. wide all round, and planting it with Hybrid Perpetual Roses, surrounded with a row of dwarf Bourbons, and edged with a row of dwarf China Roses. What kind would suit the north-west Riding of Yorkshire? and would they need protection in winter?—NOVICE.

1624.—**Plants for Window Decoration.**—Will any reader oblige by giving a list of some of the best plants to grow for the above purpose? I have a small greenhouse to forward the plants before they come into bloom. Also a list of the most suitable for carpet bedding and edging.—J. S.

1625.—**Moles in Garden.**—Can any reader kindly give advice on getting rid of these tyrants? I have tried spring and wood traps without success.—C. C. G.

1626.—**Small Gardens near Town.**—Will any reader kindly suggest the most effective way to plant a small garden near town with a south aspect laid out in beds about 9 ft. by 4 ft.? and state what kinds of plants to be used, and how to arrange them?—AMATEUR.

1627.—**Treatment of Gladioli.**—How should I treat a quantity of Gladioli bulbs I have just bought? They are no larger than a small Crocus.—F. H. B. [Prepare a bed of deep, rich, light soil in a sunny position and plant the bulbs. Should they show flower-spikes it would be well to pinch them out. Lift the bulbs in autumn, when the tops lie down, and plant again next spring, and they should flower well in summer.]

1628.—**Cropping Wet Land.**—I have five acres of land, which during winter is usually flooded, also in summers such as the last. It is at present in Grass, but I am never sure of a crop of hay. What would you advise to crop it with?—DELTA. [You could not do better than plant Osiers and Willows.]

1629.—**Cleaning Garden Pots.**—*T. B.*—Thoroughly cleanse them with scrubbing-brush and water. It is a bad plan to paint them, as the roots of the plants suffer thereby.

1630.—**Hyacinth Flower-stems Rotting.**—*Lewis W.*—Your system of treatment appears to be proper, but probably the rotting is the result of potting too deeply. There should always be one-third of the bulb free of the soil. Try this plan another season.

1631.—**Begonia Rotting.**—A yellow-flowering Begonia rotted off early in the last summer. I am afraid I gave it too much water. A fine crimson-flowering kind also got nipped by the frost. I placed both in the greenhouse and gave no water all the winter; will they spring up again?—WILLING TO LEARN. [The former is probably past recovery, the other will probably send up shoots soon if not too severely injured by frost. Withhold water until shoots appear.]

1632.—**Climber for Greenhouse.**—*C. J. W.*—Maréchal Niel, Gloire de Dijon, or Devoniensis Roses would suit your purpose well, or Clematis Jackmanni, Clianthus puniceus, Fuchsia virgata, Cobæa scandens and various others.

1633.—**Ashes in Gardens.**—How can I best utilise a quantity of fine ashes in my garden? to what vegetables will they prove most beneficial? R. C. B. [If the ashes are from wood, they are beneficial to the soil for growing all kinds of vegetables. Coal ashes are not so useful except to mix with stiff soils so as to render them more porous].

1634.—**Fumaria bulbosa and Arum Dracunculus.**—Can any one inform me as to the treatment of Fumaria bulbosa and Arum Dracunculus? I bought some at an auction. I have looked in vain for description of habit, &c., in gardening works.—BUYER. [The plants mentioned above are known more generally under other names, viz., the former as Corydalis bulbosa, the latter Dracunculus vulgaris. They both thrive in the open border, and are perfectly hardy in a dry light soil.]

1635.—**Cyclamen and Primulas not Flowering.**—They were re-potted last autumn in good soil, have been kept in a sitting-room all the winter, and look healthy; what can be the reason of their having no blooms?—TILLY SLOW-BOY.

1636.—**Re-potting Begonias.**—*Tilly Slow-Boy.*—Your plants had better be re-potted during the next month.

1637.—**Ferns in Case.**—*Mrs. R.*—Most of the common small greenhouse Ferns thrive well in a closed case. They should not be kept too wet, and it will be beneficial to admit air for an hour or two daily so as to dry up superfluous moisture.

1638.—**Tomtits in the Garden.**—Last year I constructed a box about 8 in. long by 5 in. in width and depth, after the shape of a salt box, with a sloping lid to throw off the rain, and a hole at one end of the box 1½ in. in diameter; this I fastened in the branches of a Pear tree; I also secured some wire netting 18 in. wide round the stem of the tree 4 ft from the ground, for the purpose of keeping off cats. In due course a couple of tomtits built their nest in the box and reared a family. Yesterday I noticed a number of tomtits in the garden, which leads me to think that my last year's visitors are coming back to their old quarters. Would it be advisable to remove the bird-nest from the box or allow it to remain untouched?—S. M.

1639.—**Ivy Screens.**—I want to form some screens of Ivy, from 3 ft. to 6 ft. high, for a terrace exposed to the east, south, and west. Could I plant roots in wooden boxes with success by giving plenty of liquid manure? If so, what width and depth ought the boxes to be? Would the boxes answer if placed on the terrace, or should they be sunk (in stones)? Possibly by keeping the Ivy roots in the boxes, I might grow creeping Roses in soil placed near the boxes; if so, what sort of a hole should be made for the soil for the Roses?—G. H. B. [You can establish Ivy in boxes by placing in them some well-rooted plants and some good soil, and keep moderately moist. The plants will be established better and quicker if kept in a sheltered place for some time after being planted. The size of the boxes is quite immaterial provided they are not too small. Liquid manure will do more harm than good in such a case; it is only needed when the soil becomes exhausted and the boxes full of roots. It will be better to sink the boxes, as by this means the soil will be kept more moist and cool in summer. If you grow Roses near the Ivy, the roots of the latter should not be allowed to feed on the soil intended for the Roses].

1640.—**Marechal Niel Rose.**—I re-potted a plant of this Rose in December, and at that time the sap had begun to rise and small buds were appearing. Soon afterwards the buds died and now only the stalk remains. What would you advise me to do with it?—AMATOR FLORUM. [Do not disturb the roots again, but keep the plant under glass, and do not keep the soil too moist, and wait and see what effect the genial weather which will shortly come will have upon the plant].

1641.—**Roses in Towns.**—I have a few Rose trees that at one time thrived well in my open garden, but in consequence of the extension of the town, the smoke has killed all the standards. The dwarfs are still living, but not doing well, although carefully attended to. Could I overcome the difficulty of the smoke, and induce them to thrive again were I to put them in a small greenhouse—say half pit, half greenhouse—and either pot and plunge them, or plant in beds?—QUERO. [The smoke nuisance would probably be greatly obviated by growing the plants under glass, but they will never thrive so well as in an atmosphere free from smoke, as, of necessity, the plants being hardy will require a large amount of ventilation. If placed under glass, the best way is to plant in a bed of good soil, as they then succeed better, and require less attention than when grown in pots.]

1642.—**Culture of the Bullace Damson.**—*Profit.*—The above fruit would no doubt be produced abundantly in favourable seasons in such a soil in your locality. It can be obtained at any of the large fruit tree nurseries. The Strawberries, Sir Joseph Paxton, Keen's Seedling, Sir Charles Napier, are all good kinds, and would suit your purpose well.

1643.—**Raising Seeds in Rooms.**—*F. S.*—The plan you intend to adopt will, we fear, be a failure. If the seeds do germinate the plants will be so weak and drawn that they will never make good plants when planted out. If you have no convenience to sow under glass in a gentle bottom heat, wait a little longer until the weather becomes warmer, and then you can raise strong seedlings which will be nearly as forward as an earlier sown batch.

1644.—**Orange Tree Culture.**—I shall be glad to know how to proceed in the cultivation of a dozen Orange trees raised last summer from seeds. They are now 3 in. or 4 in. high, with three or four leaves on them. They have been raised in pots in garden soil under inverted

tumblers; no growth has taken place for many weeks. How high, and when should these plants be grafted?—J. C. [The Orange tree requires a greenhouse temperature, but it may be grown successfully in a dwelling-room provided the leaves of the plants are kept quite clean from dust, &c. They require to be potted in a mixture of loam with a little sand and decayed manure. The pots should be not unproportionately large to the size of the plants, and they should at no time be kept too moist at the roots. Grafting Orange trees is a precarious operation unless practised by some one who thoroughly understands it and is an expert. Besides, if the plants in question have been raised from pips of ordinary Oranges, they do not require grafting.]

1645.—**Culture of Egg Plants.**—*R. D.*—The seeds of this plant should be sown in spring; they require to be grown in a mixture of turfy loam and a little sand and decayed manure.

1646.—**Spiræa japonica.**—*R. D.*—You may safely divide your plants for the purpose of propagation. It may be done any time before the summer.

1647.—**Magnum Bonum Potatoe.**—I have some very large sets of these Potatoes; is it best to cut them now, or wait till I plant them?—A. K. [You had better cut them into the necessary portions now, as they are less likely to rot.]

1648.—**Artificial Manures.**—What is the best kind of prepared manures to use for Roses, Geraniums, Fuchsias, Hydrangeas, and Lilies?—F. A. W.—[Try Amies' Manure or Clay's Fertiliser (see advertising columns).]

1649.—**Lobelias for Bedding.**—Which are the best dwarf Lobelias for bedding? I have L. erinus speciosa and Blue Beauty.—L. [Add to these Blue Stone, White Perfection, Brighton, Ebor, and Defiance.]

1650.—**The Culture of the Hoya.**—This plant requires the temperature of a stove or warm greenhouse, in order to induce it to flower freely. It requires similar treatment as that of ordinary pot plants, except that it does not need so much water, especially during winter.

1651.—**Treatment of Roses Under Glass.**—I have a small conservatory in which I want to grow Roses. Could you give me a few hints on their general management? [Plant them out or pot them in good soil (not too sandy), as near to the glass as possible. Give them copious waterings in the summer and frequent syringings. Keep them perfectly free from insect pests by fumigating, &c. Give plenty of ventilation in fine weather, especially during summer. Prune the shoots well back every autumn, and, if necessary, give a coating of compost on the stem, so as to eradicate scale, &c.]

1652.—**Stable Manure for Hotbeds.**—Will you inform me what condition stable manure should be in to form a hotbed? Last year I used that which had been at the bottom of the pit and was quite rotten and hot when put into the frame, but it became cold in a few days. Is it better to use it fresh from the stable? or is one cart-load too small in quantity to retain the heat?—*E. G., Hull.* [It is best to use fresh manure, *i.e.*, that in which the straw is not much decayed. The fermentation then goes on for some considerable time, and the heat is retained, whereas in old and too much decayed material the heat is soon dispelled. A waggon-load will make a fair-sized bed, and ample for ordinary purposes.

1653.—**Culture of Hardy Flowers.**—Spiræa filipendula and palmata, Veronica incana, and Tradescantia purpurea will all thrive well in any soil in the open border. The last named is more tender than the others, and should have the most protected spot.

1654.—**Happy Thought Geranium.**—I have one of these which I am afraid will die: it was cut down in the autumn, and since then it has only produced sickly yellow shoots, which grow about 2 in. and then damp or fade off. Can I do anything to save it?—GLADIOLUS. [Put it in a light airy position, and water sparingly.]

1655.—**Cucumbers on Old Hotbed.**—I have just made up a hotbed in a frame for raising various seeds; would a Cucumber grow on it during the summer after the seeds are taken out? I do not want to grow the hardy ridge, but a frame Cucumber. Is there any chance of success?—GLADIOLUS. [A frame Cucumber, such as Hedsor Prolific or Lord Kenyon's Favourite, would do well in such a position.]

1656.—**Transplanting Parsley.**—I have in my garden two rows of Parsley plants which have survived the winter. As I cannot let them remain where they are, could they be transplanted with any chance of success?—NOVICE. [They would succeed if transplanted, but would be liable to run to seed should dry weather set in.]

1657.—**Bottom-heat for Seeds.**—Having adopted one of the modes of starting seeds by means of a lamp and hot-water tin mentioned in GARDENING, I shall be glad to know whether I should take the seeds out of the heat as soon as they have started. I may mention the temperature of my greenhouse is about 45°.—MARK. [When well up reduce the heat by lowering the lamp; finally take them out altogether, and place on the greenhouse shelves. Something depends on what seeds they are.]

1658.—**Potato Planting in Town Garden.**—I am making a rockery across the lower end of my garden for Ferns, &c.; the slope at the back of it I think of planting with Potatoes; shall I do so with any chance of success, the space at disposal being 16 ft. by 8 ft., soil rather heavy and retentive, aspect south but partly shaded on south side by a 6-ft. wall? If advisable, what kind will be best? and when shall I plant?—J. G. S. [You might possibly get a fair crop, but it is rather doubtful. Try the Early Ashleaf. Plant early in April.]

1659.—**Leaves Falling off India-rubber Plant.**—What is the matter with an India-rubber plant, the leaves of which are the enclosed? It was taken from the greenhouse into a hall, where it was exposed to gas and draughts, and when it remained a couple of months or longer. Just before Christmas it was returned to the conservatory, and ever since has been growing worse. It is a large plant, but has now not a single healthy leaf. Should it be cut down? if so, how must it be treated? or what shall be done with it?—WYBORNE GATE, *Southport.* [The reason of the leaves falling off the India-rubber plant is its being exposed to gas by night and cold air by day. You had better cut the plant down and place it in a warm house, and it will soon push up new growth. If the stem be cut into segments and put into a hotbed, a stock of young plants may be got.]

1660.—**Cucumbers and Melons in Small Greenhouse.**—I have built a lean-to greenhouse, 8 ft. long by 6 ft. wide, against the end of my house, with a glass roof and front. It faces south, and will receive full force of sun from sunrise until about 6 p.m. during summer. Can I grow Cucumbers and Melons in such a house without the aid of fire-heat? If so, what are the most suitable sorts, the best time to plant, and with what materials should the bed be prepared for them? Also what fruit tree will do best against the back wall, the height of which is 9 ft.? Will the heat from a small stove with fire-box about 1 ft. square be beneficial to the plants during nighttime if placed inside the house?—P. F. J. [Cucumbers or Melons might be grown in summer in such a house separately, but together we fear you would not succeed very well. The Cucumbers would need a slight shade from direct sunshine; Melons could not have too much sun. The soil may be put in mounds on a platform of planks in front of the house, and the plants be trained under the roof on wires. The soil for Cucumbers should be light and rich, and that for Melons rather stiff and poor. The Telegraph is the best Cucumber, and Victory of Bath is an excellent Melon.]

1661.—**Treatment of Fine-foliaged Begonias.**—I have a Begonia which has been doing well in a room without fire during the whole of the winter. It is apparently growing out of the pot. Should it be divided? if so, how? what soil is required? and the best time for doing it? [If not convenient to give the plant a larger pot, cut it through the middle with a sharp knife, leaving strong stems on each piece, of course. Soil, peat or good sandy loam and leaf-mould.]

1662.—**Potting the India-rubber Plant.**—I have a large India-rubber plant; in what kind of soil shall I repot it? does it require much water? would liquid manure assist its growth?—B. G. F. [Almost any open soil will do. Chopped turf or peat with sand and leaf-mould or rotted manure added will grow it well. When the pot is full of roots, liquid manure will be an advantage. When in active growth the plant needs plenty of water.]

1663.—**Sowing Seakale.**—Which is the best time to sow Seakale seed? and will the roots be strong enough for forcing next spring?—J. M. [Sow at once in rich soil; thin out the plants if too thick. Keep the surface of the soil frequently stirred with the hoe during summer, and give liberal supplies of manure water during dry weather. Some of the largest roots might do for forcing in spring, but by rights they should have another year.]

Yearly Volume of "Gardening Illustrated."—*J. W. G.*—The bound yearly volume will shortly be ready.

Measurement of Flower-pots.—*J. S.*—The diameter is measured across the top of the pots.

Pomegranate.—*F. W.*—You can procure this plant from any of the large nurseries in London; the present is the best time to obtain it.

Botanical Names.—*F. A. M.*—The name of the Aaron's Beard is Spiræa aruncus, that of Stag's-horn Moss Lycopodium clavatum. The former will thrive in any soil in the open air. The latter, though a native plant, is somewhat difficult to manage under culture. The conditions under which it is found wild should be imitated as near as possible.

GROWING ALPINE AND ROCK PLANTS.

THERE is no class of plants which affords the amateur cultivator more interest and pleasure than a good and well arranged selection of what are called alpine plants. Even in the smallest gardens they may be grown if care be taken at planting; yet we seldom see a rockwork planted with alpine flowers in either large or small gardens worthy of the name of a rockery. There are many places in which a sort of sloping stone or burr wall passes as "rockwork," a dust of soil being shaken in between the stones, and the whole so arranged that if you do cover it with suitable plants they perish speedily. In others, made upon a better plan as regards the base, the "rocks" are all stuck up on their ends, and so close that soil, or room for a plant to root, is out of the question. The best thing that usually happens to a structure of this sort is that its nakedness gets covered by a Cotoneaster, or some friendly climbing shrub, or some rampant weed, of course to the exclusion of true rock-plants; but in most cases the attempted rockwork is a standing eyesore.

A TUFT OF ALPINE AND ROCK PLANTS.

Although hundreds of brilliant alpine flowers may be grown without a particle of rock near them, yet the slight elevation given by rockwork is very congenial to numbers of the most valuable kinds. A tastefully disposed rock-garden furnishes a home for many pretty native and other interesting plants which may not safely be put elsewhere; and therefore it is important that the most essential principle to be borne in mind when making it should be generally known. The chief mistake generally made is that of not providing a feeding-place for the roots of the plants that are to embellish the rockwork. On ordinary rockwork even the coarsest British weeds cannot find a resting-place, simply because there is no body of soil or matter into which the descending roots can penetrate and find nourishment sufficient to keep the plant fresh and bright and well in all weathers.

The position selected for the rockery should never be near walls; never very near a house; never, if possible, within

view of formal surroundings of any kind. It should generally be in an open situation; and of course a diversified spot, or one with bold prominences should be selected, if available. No effort should be spared to make all the surroundings and every point visible from the rockwork as graceful, quiet, and natural as they can be made. The part of the gardens around the rockwork should be picturesque, and in any case display a careless wildness resulting from the naturalisation of beautiful hardy herbaceous plants, and the absence of formal walks, beds, &c. No tree should occur in or very near the rock-garden; hence a site should not be selected where it would be necessary to remove valuable or favourite specimens. The roots of trees would be almost sure to find their way into the masses of good soil provided for the choicer alpines, and thoroughly exhaust them. In small places, and in those where from unavoidable circumstances the rock-garden is made near a group of trees, the roots of which might rob it, it would be a good plan to cut them off by a narrow drain, descending as deep as, or somewhat deeper than, the roots of the trees; this should be filled with rough concrete, and it will form an effectual barrier.

Materials for a Rockery.

As regards the kinds of stone to be used, if one could choose, sandstone or millstone grit would perhaps be the best; but it is seldom that a choice can be made, and happily almost any kind of stone will do, from Kentish rag to limestone; soft, slaty, and other kinds liable to crumble

Corner of a ledge of Rock covered with Alpine Flowers.

away should be avoided, as also should magnesian limestone. It can hardly be necessary to add that the stone of the neighbourhood, if not very unsuitable, should be adopted for economy's sake, if for no other reason. No burrs, clinkers, portions of old arches and pillars, broken-nosed statues, &c., should ever obtain a place in a garden devoted to alpine flowers. Stumps and pieces of old trees are quite as objectionable as any of the foregoing materials; they are only fitted to form supports for rough climbers, and it is rarely worth while incurring any expense in removing or arranging them. Begin without attempting too much. Let your earliest attempts be confined to a few square yards of earth, with no protuberance more than a yard or so high. Be satisfied that you succeed perfectly with that before you try anything more ambitious. Never let any part of the rock-garden appear as if it had been shot out of a cart. The rocks should all have their bases buried in the ground, and the seams should not be visible: whenever a vertical or oblique seam of any kind occurs it should be crammed with earth, and the plants put in this will quickly hide the seams. Horizontal fissures should be avoided as much as possible; they are only likely to occur in vertical faces of rocks, and these should be avoided except where distant effect is sought. No vacuum should exist beneath the surface of the soil or surface-stones. In all cases where elevations of any kind are to be formed, the true way is to obtain them by means of a mass of soil suitable to the plants, putting a rock in here and there as the work proceeds; frequently it would be desirable to make these mounds of earth without any strata or "crags." The wrong and the usual way is to get the desired elevation by piling up masses of rock.

No formal walk—that is to say, no walk with regularly-trimmed edges of any kind—should ever be allowed to pass through, or even come near, the rock-garden. This need not prevent the presence of properly-made walks through or near it, as, by allowing the edges of the walk to be a little irregular and stony, and by permitting dwarf Sedums, Saxifrages, Linaria alpina, the

Alpine Plant on Border, surrounded by half-buried stones.

lawn Pearl-wort, etc., to crawl into the walk at will, a perfectly unobjectionable effect will be produced. In every case where gravel walks pass through ferneries or rockeries, and are fringed by stonework, a variety of little plants should be placed at the sides, and allowed to crawl into the walk in their own wild way. There is no surface whatever of this kind that may not be thus embellished with interesting subjects. Violets, Ferns, and the early Forget-me-not (Myosotis dissitiflora), &c., will answer best for the moister and shadier parts; while the Stonecrops, Saxifrages, Arenarias, and many others, will thrive in more arid parts and in the full sun. The whole of the surface of the Alpine garden should be covered with plants, except the projecting points or crags; and even these should be covered, as far as possible, without completely concealing them. In moist districts, such Alpines as Erinus alpinus and Arenaria balearica will grow wherever there is a resting-place for a seed on the face of the rocks; and even tall and vertical faces of rock may be embellished with a variety of plants; so that there is no reason whatever why any level surfaces of ground should be bare.

In no case should regular steps be permitted in or near the rock-garden. Steps may be made quite irregular, and not only not offensive to the eye, but very beautiful, with Violets and other small plants jutting from every crevice. No cement should be used in connection with the steps. The engraving on page 16 shows very imperfectly—no engraving could show it otherwise—the crowds of lovely plants that gather over it, except where worn bare by feet, thriving year by year as freely as they do on the most favoured spots in the Alps. In cases where the simplest type of rockwork only is attempted, and where there are no steps or rude walks in the rock-garden, the very fringes of the gravel walks may be gracefully enlivened by allowing such plants as the dwarfer Sedums to become established in them. The Alpine Linaria is never more beautiful than when self-sown in a gravel walk. It must not, however, be supposed that heaps of stones or small rocks are absolutely necessary for the health of alpine plants. The great majority will thrive without their aid if the soil be suitable; and though all are benefited by them, if properly used as described, it is important that it should be generally known how needless is the common system of inserting mountain plants among loose stones, burrs, &c. Half-burying rocks or stones in the earth round a rare species, which it is intended to save from excessive evaporation, and which has a deep body of soil to root into, is, however, quite a different and an excellent practice.

Soil.—The great majority of alpine plants thrive best in deep soil. In it they can root deeply, and when once they are so rooted they will not suffer from drought, from which they would quickly perish if planted in the usual way. Three feet deep is not too much for most species, and it is in nearly all cases a good plan to have plenty of broken sandstone or grit mixed with the soil. Any good free loam, with plenty of sand, broken grit, etc., will be found to suit the great majority of alpine and dwarf herbaceous plants. But peat is required by some, as, for example, various small and brilliant rock-plants like the Menziesias, the Wood Lily (Trillium), Lady's Slipper (Cypripedium), and a number of other mountain and bog plants. Hence, though the general mass may be of the soil above described, it will be desirable to have a few masses of peat here and there. This is better than forming all the ground of good loam and then digging holes in it for the reception of small masses of peat. The soil of one or more portions might also be chalky or calcareous, for the sake of plants that are known to thrive best on such formations, as the pretty Polygala calcarea, the Bee Orchis, Rhododendron Chamæcistus, etc. Any other varieties of soil specially required by individual kinds can be given as they are planted.

In the construction and planting of every kind of rockwork, it should be distinctly remembered that every surface may and should be embellished with beautiful plants. Not alone on rocks or slopes, or favourable ledges, or chinks, or miniature valleys, should we see this kind of exquisite plant life. Numbers of rare mountain species will thrive on the less trodden parts of footways; others, like the two-flowered Violet, seem to thrive best of all in the fissures between the rude steps of the rockwork; many dwarf succulents delight in gravel and the hardest soil, and numerous other plants will run wild in any wood or among low shrubs near the rock-garden.

Miniature Rock-gardens.

Hitherto we have considered the rock-garden on a somewhat extensive scale. As those who can afford this are less likely to want instruction than the much greater numbers who cannot, we now treat of successful modes of growing alpine flowers which may be carried out in the smallest gardens at a trifling expense. A well-arranged and well-planted alpine garden is somewhat costly, even where materials are easily obtained, and, moreover, requires much labour, skill, patience, and knowledge of plants to keep it in a perennially interesting condition. Local conditions, want of suitable materials, want of knowledge, and consequent want of interest in the plants, must, in many cases, prevent this most interesting phase of gardening from being enjoyed. I am therefore the more desirous to help the smaller and humbler attempts of those who cannot afford more than a very small patch of alpine garden, as well as to assist beginners of every class.

One of the simplest of all ways of cultivating alpine beds is in small rocky beds, arranged on the turf of some parts of the garden cut off by trees or shrubs from the ordinary flower-beds, without any of the pretensions of the ordinary rockwork; one of these will give much greater satisfaction than many a pretentious "rockwork," and by the exercise of a very little judgment is readily constructed so as not to offend the nicest taste. I once induced the owner of a garden in the northern suburbs of London to procure a small collection of alpines and try them in this way, and the result was so charming that a few words as to how it was attained may be useful.

A little bed was dug out in the clay soil to the depth of 2 ft., and a drain run from it to an

A large half-buried stone surrounded by Alpine Plants.

outlet near at hand; the bed was filled with fine sandy peat and a little loam and leaf-mould, and, when nearly full, worn stones of different sizes were placed around the margin, so as to raise the bed on an average 1 ft. or so above the turf. More soil was then put in, and a few rough slabs, arranged so as to crop out from the soil in the centre, completed the preparation for the neater Sedums and Sempervivums, such Saxifrages as S. cœsia and S. Rocheliana, such Dianthuses as D. alpinus and D. petræus, Mountain Forget-me-nots, Gentians, little spring bulbs, Hepatica angulosa, etc. They were planted, the finer and rarer things getting the best positions, and, when finished, the bed

looked a nest of small rocks and alpine flowers. In about eight weeks the plants had become established, and the bed looked quite gay from a dozen plants of Calandria umbellata that had been planted on the little prominences flowering profusely. This made the arrangement equal to one of bedding plants from the "effective" point of view. Another was made in the same manner, with more loam, however, and planted with subjects as different from those in the other bed as could be got, confining them, however, to the choicest alpines, except on the outer side of the largest stones of the margin, where such plants as Campanula carpatica bicolor were planted with the best results.

The only attention these beds required after planting was to keep a free-growing species from overrunning a subject like Gentiana verna, to water the beds well in hot weather—to keep them in fact thoroughly moist—and to remove even the smallest weeds. With the exception of the exquisite Gentiana bavarica, every alpine plant grew well, and the beds presented fresh floral interest every week from the dawn of spring till late in autumn.

The preceding plan can be carried out in the very smallest places. The following is quite as easily adopted on the fringe of any shrubbery. An open, slightly elevated, and, if possible, quite isolated spot should be chosen, and a small rock-garden so arranged as to appear as if naturally cropping out of the shrubbery. With a few cart-loads of stones and earth excellent effects may be produced in this way. The following illustration well explains my meaning; it represents an irregularly sloping border, with a few mossy bits of rock peeping from a swarming carpet of Sandworts, Mountain-pinks, Rock-cresses, Sedums and Saxifrages, Arabises and Aubrietias, with a little company of fern-fronds sheltered in the low fringe of shrub behind the mossy stones.

Having determined on the position of the bed, the next thing to do is to excavate the ground to a depth of 2 feet, or thereabouts, and to run a drain from it if very wet. If not, it is better let alone, as a good deal of the success depends upon the beds being continually moist; and in dry soils, instead of draining, it would be better to put in a substratum of spongy peat, so as to retain moisture for the stony matter that the cavity is to be filled with. As to soil, rock-plants are found in all sorts; but a good turfy loam, with plenty of silver or river sand added, will be found to suit a greater number of kinds than any other. The compost should be of a somewhat spongy character, and if not naturally so, it should be so made by the addition of well decomposed leaf-mould, cocoa-nut fibre, or, failing these, peat. If the trees of the shrubbery are of a nature likely to send their roots into the mass of good compost prepared for the rock-plants, it will be desirable to dig a narrow drain as deep as their lowest roots, and fill it with concrete to the surface; this will prevent the alpine plants from being starved by their more vigorous neighbours.

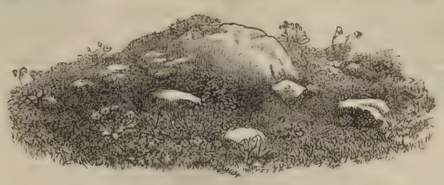
With the soil should be incorporated the smallest and least useful stones and débris among those collected for the work, so that the plants to adorn the surface may send down their roots through the mixture of earth and stone, and revel in it. When this is well and firmly done, the larger stones may be placed—half in the earth as a rule, and on their broadest side, so that the mass, when completed, may be perfectly firm. Have nothing to do with tree roots or stumps in work of this kind; they crumble away, and are at best a nuisance and a disfigurement to a garden. The intervening spaces may then be filled up, half with the compost and half with the stony matter, and the smaller blocks placed in position—the whole being made as tastefully diversified as may seem desirable, taking the size of the structure into consideration. When finished, it should look like a bit of rocky ground, stones of different shapes protruding—here a straight-sided one, under the lee of which a shade-loving plant may flourish; there two in juxtaposition, between which a cliff alpine may find a place. Two or three feet will as a rule be high enough for the highest points of rocky fringes of this sort, though the plan admits of considerable variation, and it may be tastefully made twice or thrice as high.

Alpine Plants on Window Sills.

We will next consider the case of the owners of those limited sites for gardens—window sills. On these numbers of diminutive and interesting alpine plants may be easily grown. My first proposal is to pick out some of the prettiest and most diverse of the Stonecrops, Sempervivums, silvery Saxifrages, etc., to plant them in a goodly sized box, and use a few rough stones by way of miniature rocks. I would place the box or boxes in the full sun, and give them plenty of water

Alpine Plants on level ground.

from a rose in warm spring and summer weather, and, indeed, at all times when they are dry, which is not likely to occur often during the dull months of winter. Among and between the alpine plants I would in autumn place here and there a diminutive spring-flowering bulb—say Bulbocodium vernum, Scilla sibirica, and S. bifolia, small Daffodils, Snowdrops, Snowflakes;



Small rocky bed of Alpine Flowers.

and, if the box be large, a few of the delicately coloured Crocuses. The boxes should never be taken indoors, except for re-arrangement. When the snow comes the plants are comfortable, as it is their natural protection in a wild state; frost or rain hurts them not, and even London smoke is not able to destroy their little lives if they are well attended to. The boxes most suitable for this purpose are wooden ones, with zinc troughs, decorated externally with chippings of Oak and Apple trees, Fir cones, etc.; or what may be called architectural boxes, of wood also, but painted stone-colour externally, and designed so as to suit buildings, which the rustic ones do not. Both these kinds of boxes are made in good form by various firms in London and elsewhere. No matter what pattern is adopted, it is desirable to allow some plants of a trailing habit to fall over its outer edge. If the outer margins of the boxes were well covered, it would matter little what form were used. The common Stonecrop, Sedum Sieboldi, Thymus lanuginosus, the woolly-leaved Cerastiums, and many other hardy plants will do this effectively.

A yet more satisfactory window rock-garden can be made outside of a window to which light has free access, by forming a miniature alpine garden on the sill. It is done by simply putting a few irregular stones along the front margin, and packing a few small bits of turfy peat or loam inside them to prevent the fine soil, afterwards to be added, from being washed out. Then fill in the hollow with sandy loam, mixed, if convenient, with morsels of broken sandstone. A few mossy or ancient-looking stones should be half-buried on the upper surface, and then the whole should be planted, the best time to do this being in April. It is not merely possible to keep alpine succulents in this way: it is easy to grow a multitude of the most interesting and beautiful kinds. I never in garden or wild saw these plants in better health, or looking more at home, than on the outside of a low sunny window in Mr. Peter Barr's house at Tooting. The accompanying figure shows a view of this from the interior; it was no less pretty seen from without. It is, however, impossible to show in an engraving the exquisite effect of the Liliputian succulents. The attention required is very trifling: some little taste in forming and planting, a judicious selection of plants, and thorough waterings through the dry season. I need hardly add that small and brilliant-flowering spring bulbs might be employed to light up this tiny garden in spring as well as that previously mentioned. It would also be desirable to plant subjects of a drooping character on the outer margin. The alpine succulents are all thoroughly hardy, and would remain in good condition during the winter, but a little changing and re-planting every spring would be very desirable.

Alpine Garden on window sill.

Planting.—There is a mischievous way of planting almost every kind of small plant, which is very injurious in the case of hardy Orchids (the roots of which are easily injured) and of all rare hardy plants. I refer to the practice of making a hole for the plant, and after a little soil has been shaken over the roots, pressing heavily with the fingers over the roots and near the neck of the unfortunate subject. What is meant will be understood from fig 2, if the reader assumes that there is a little soil between the fingers and the roots. Where the roots are not all broken off in this way, many of them are mutilated, or those near the collar of the plant are thrust deeper into the earth. Not unfrequently plants perish from this cause. The right way, after preparing the ground, is to make it firm and level, and then make a little cut or trench. The side of this trench should be firm and smooth, and the plant placed against

Planting Alpine and other Plants.

it, the roots spread out, and the neck of the plant set just at the proper level, as in fig. 1. Then a good deal of the fine earth of the little trench is to be thrown against the roots, and as much lateral pressure applied as may be necessary to make the whole quite firm. Once the subject is carefully planted, as much surface-pressure as you like may be given. In this way not a fibre of the most fragile plant will be injured. This, of course, only applies to subjects not planted with balls, and is the best way to plant them.

Selections of Alpine or Rock Plants for Various Purposes.

Dwarf Alpine or Rock-plants that will Thrive in Ordinary Soil on the Level Ground.

Acæna microphylla
Acantholimon glumaceum
Achillea tomentosa

*lanceolatum
*Trichomanes and varieties
*viride
*Ceterach officinarum
*Matthiola tristis

R.

Carpet Beds of Flowering Plants.—Not having seen in GARDENING a description of centre beds similar to those I had last year and intend having again this year, I wish to describe them to you, as they were very much admired, and perhaps some of your readers would like to try them. In the first place, the beds were made in the Italian style, with Box edgings, star-shaped, having in the centre of each a standard Rose 4 ft. high, with, of course, a strong stake to prevent it from swaying with the wind. Round the butt of each Rose I had carmine Candytuft; then a circle of white Candytuft; next a double circle of dark purple Pansies; then a double circle of yellow-ground Odier Pansies, and so on with Pansies. the colours contrasting, until the bed was filled nearly to the Box, inside of which was sown a row of Mignonette. At each point of the star short hooked stakes were driven firmly into the ground, and a line of oiled twine was then strained tightly from each short stake to the summit of the Rose-prop and tied firmly, thereby preventing any possibility of the Rose tree being stirred by strong winds. Close to the hooked stakes I sowed Convolvulus major, which I trained along the cords until they reached the Rose tree, where they (the Convolvulus) were nipped—the whole, when in bloom, presenting a beautiful sight, the Convolvulus hanging gracefully in festoons, partly shading the Pansies from what they do not like, the strong sun. The Pansies were kept blooming for a long time by nipping back long shoots and keeping decayed flowers and seed-pods well cleared away. Should any of your readers desire to try the experiment, they could, of course, vary the plants and colours according to taste, but I am sure the idea, if tried, would please many.—G. DOWNIE C. ELLIS, *Ivy Cottage, Churchtown, Co. Dublin.*

The Royal Fern.—I remember years ago being at Beddulth Grange grounds and gardens. I then saw Osmonda regalis in perfection. Nowhere else, indeed, have I seen this Royal Fern so fine as it was there, but not growing, as Mr. S. Piran recommended lately in GARDENING, with its crown under water, but on the side; and every instance when I have seen it—that is, doing well—it has been in similar situations. Perhaps, under the circumstances, Mr. Piran will excuse my calling attention to his recommendation. I myself should be glad to have the experience of one who has tried Mr. Piran's plan before I should venture on it myself.—JAS. CARR.

Substitute for Bedding Plants.—Having been unfortunate last season in losing all my Geraniums through the severity of the winter, it may interest those of your readers who may be so situated this year to know what an excellent and inexpensive substitute they may find in the large-flowering, common Ten-week Stock. They should purchase, at a cost of two shillings, one of the German collections imported from Erfurt, containing 800 seeds in eight varieties. Every seed can be relied on to germinate, and fully two-thirds to come double. Sow them in the ordinary way, in flat wooden boxes or seed pans, and place them in a cool frame. As soon as they will bear handling, carefully prick them out, without disturbing the mould adhering to them, placing in 3 in. pots filled with a mixture of wet rotten manure from an old cucumber frame, and good loam. Open the lights on every favourable opportunity, to prevent the plants becoming drawn. The Stock, like Mignonette, is a spare-rooted plant, and does not bear transplanting well, and I think is even better sown in the pots in which it is to remain, though the former plan is much more convenient, and if carefully done the removal is attended with a minimum of injury. By the usual bedding-time the plants will be ready, and may be set out about 12 in. apart, taking great care not to disturb the ball. The ground needs no special preparation; the only thing I do is to make the holes a little deeper than they are wanted, and deposit at the bottom some good rotten manure. Take care to reserve a few plants to replace any that may fail or come single. A good soaking of guano just before coming into bloom will greatly benefit them, and as soon as the main flowering stem is done, carefully remove it, and another application or two of some fertilising compound will cause lateral branches to shoot forth nearly equalling the main stem in size and beauty, and so carry on the display until the close of summer. My plants grown in this way were the admiration of every one; and this lovely flower, if properly cultivated, for proportion of flower to leaf, duration of bloom, and variety of colour, will challenge comparison with any of the well-known bedding plants, and for fragrance stand *facile princeps*. The wonder is that it is not more generally grown, and I can promise that any of your readers who will follow these few simple directions will find themselves amply repaid.—LEWIS W.

Rockery of Alpine plants in front of a Shrubbery.

HOW TO GROW DAHLIAS.

DAHLIAS may be propagated by means of cuttings, layers, root-divisions, or seeds; the latter being only used where new varieties are a desideratum. Cuttings are, undoubtedly, the best means by which Dahlias may be increased, and by these they may be multiplied to any extent; division of the roots is very commonly practised, but cuttings are, as I have said, best. When propagated by division, the tuber or tubers left, if they survive the summer, generally decay when stored, and communicate disease to the young plants. When cuttings are used, each has its own self-formed tubers, and they are on that account less liable to rot during the winter. If started in February or March, in a temperature of 65° to 70°, each crown will produce three or four cuttings every two or three days; which may be taken off even as early as March, removing them close to the crown, but taking care not to injure it, as others will come up at the base of those removed. It is also necessary for the growth of good plants not to let the cuttings become too long before taking them off the tubers, as they are more apt to flag, need more room, and are not so convenient to plant out as short cuttings. When the crowns have supplied all the cuttings that can be got from them, they may then be divided, if required; consequently nothing is lost.

To propagate from layers the lowest branches of the plant must be taken as early as possible, and should be pegged down in the soil, in which, if of a sandy nature, they will root freely; in the absence of sandy soil, a quantity of leaf-mould, with a good admixture of sand, may be laid down for them to root in. Pure white sand alone I find to be best suited for striking them in, and a mixture of leaf-mould and sand is very good for starting the crowns in. Cuttings may be successfully struck during the summer months; but this is seldom done except in the case of choice varieties. Three-inch pots are well adapted for putting the cuttings into, six cuttings being put in each pot, which should be plunged in a brisk bottom-heat, covered with hand-glasses, and shaded from bright sunshine; in less than a fortnight they will all be rooted, and may be potted off singly into large 3-in. pots, which may be put into lower temperatures gradually until, say May 1, when they may be put out-of-doors until required for planting.

It is necessary for Dahlias, as well as for other tender bedding plants, to have them in a situation where they may be easily protected in case of frost, as, in the event of the thermometer getting as low as the freezing point, they would be greatly injured, if not killed outright. Dahlias are seen to most advantage when planted in masses in large beds. For this purpose the tallest should be collected for the centre or background, as it may be, mixing the colours as well as possible. They should be planted 3 ft. or 4 ft. apart, and as they advance in growth all the lower branches cut off about 1 ft. from the ground. When a shrubbery is in any way unsightly, and has a border in front, a row of Dahlias often sets it off to advantage; and I have also seen a ribbon border backed by Dahlias with good effect. Staking and tying out the shoots must be particularly attended to, as the stems are very brittle, and break under the least wind-pressnre.

Earwigs are great enemies to Dahlias, but they may be trapped by using small round troughs, which may be procured at any pottery. They may also be caught in pieces of Hemlock stems, 6 inches long, leaving a joint on one end, and sticking the pieces here and there through the Dahlias. Small pots, with a little bit of dry Sphagnum Moss inside, inverted on the tops of stakes, likewise form good traps. As regards stimulants, manure-water of the strongest character may be safely used after the plants show flower, provided it be administered in the evening. Some Dahlias will produce all their flowers, or nearly so, perfect; others require their shoots to be well thinned, and all blooms except three or four to be cut off, in order to be eligible for show purposes; but, as a general rule, all may be more or less thinned. Dahlia roots have kept well and flowered for years in succession, in dry soils especially, when the plants have been cut down to the ground, and covered with some material to protect them from frost.—J. M.

Phlox Drummondii.—In some old-fashioned gardens, this is never absent during the summer months, and it is always a welcome guest in the floral circle. The seed should be sown about the first week in March in shallow pans or boxes, using a light rich soil, and placing the seeds in a nice warm and rather moist temperature. As soon as the plants can be

handled without injury, it is a good plan to prick them off into boxes, or on a bed in a warm house, in a temperature of from 50° to 60°. They soon make growth, and as the weather gets warm out of doors the boxes should be placed out in the shade to harden the plants. Those growing in a bed should be again transplanted to a prepared bed in a cold frame, and kept covered for a few days, and hardened gradually. When the plants are from 3 to 4 inches high they should have the main shoot pinched out; this induces them to make a lateral and bushy growth, and greatly assists the prolongation of the period of flowering. The soil in which the plants are to grow should be rich; an abundance of decayed leaves suits the Phlox well. The bed should be in a position fully exposed to the sun; as long as there is a good moist soil at the roots they will not be injured in the hottest bright weather.—Q.

VEGETABLES.

EARLY POTATOES WITHOUT GLASS.

IN any out-of-the-way part of the garden, where the ground is level and well exposed to the south and west sun, take out a pit, running east or west, in length according to your means and accommodation, in width 7½ f., and in depth 2 ft. at the front and 1 ft. at the back, which will leave the bottom with a good slope to the south. This done, procure a sufficient number of stout Larch or other posts 9 ft. long; char their bottom ends about 3 ft. up, and sink them that depth, including the excavated foot, along the back of the pit, about 8 ft. apart, taking care to have the tops level and in a line. This will leave them standing 6 ft. above the ground. Then nail a stout rail along on the tops of the posts, allowing it to project 1 in. over towards the pit; nail another rail along the bottom of the posts on the same side, about 6 in. above the ground line, and upon those nail, vertically, rough boards 6 ft. long, keeping their top ends flush with the top rail, which will allow the bottom ends to touch the ground or thereabout; for, as the pit has to be filled up above the ground line at the back, it is needless to allow the boards to project below that line. Boards about ¾ in. thick will do, and in nailing them on see that the edges meet closely. The back finished, sink a corresponding number of posts similarly prepared, and about 3½ ft. long, along the front of the pit, each opposite its neighbour at the back, allowing their tops to stand 15 in. above the ground; nail another rail on the top of these, and lastly nail slight rails across the pit on every pair of posts, at the angle formed by the back and front lines, and the framework is completed. It is not needful to board up the 15-in. space between the ground and the rail on the top of the front posts, for such would only shade the Potatoes from the sun. It is a good plan to pitch the woodwork over to preserve it; and this having been done, proceed to form the Potato bed as follows.

If the situation is a wet one, put at least 6 inches of drainage in the bottom of the pit, and lay a row of 2-inch drain tiles along the front, just inside the posts, to carry off any water that may collect to the nearest drain or outlet. If, however, the situation is dry and the subsoil porous, no drainage will be necessary; but whenever there is the slightest doubt of the water stagnating for the shortest period drain well, for on this hinges much of the success in keeping up a high root temperature. This is an all-important matter where the sole dependence is upon sun heat; for we know that the capability of any soil to absorb and retain heat is just in proportion to its dryness. The drainage materials may consist of rough stones or cinders for the bottom, and smaller stones for the top. If sods to cover the drainage before putting the soil in cannot be procured, more care must be taken in completing the drainage by filling up the crevices, so that the soil may not eventually work down among the stones and choke it up. Loam that has been laid in a heap until the fibre is dead should form the staple of the soil; and if this cannot be got conveniently, ordinary good garden soil will do. In either case it should be lightened with plenty of leaf-mould and peat, or either of these alone; but we recommend peat, and also a good proportion of charcoal or charcoal dust, in order to give the compost as dark a colour as possible, so as to increase its heat-absorbing power to the utmost. In this respect charcoal is a powerful agent, not to speak of its lasting manurial qualities.

The compost may be prepared any time during the winter, as opportunity offers; but the pit need not be filled with it in the first instance, at least until planting time. Afterwards it will not be needful to change the soil every year, but only add a dressing of fresh loam or manure. Eighteen inches of soil will be ample, and this, with the 6 inches of drainage, will raise the bed up to the ordinary ground level in front, and 1 foot above it at the back against the boards, which may be buttressed behind to the same depth by the soil which is taken out in excavating the pit. If these directions are carried out, the bed will slope well to the sun when finished, when we must turn our attention to the covering for the pit. Many kinds of sheeting are recommended for horticultural purposes; but nothing equals "frigi domo" as a frost protector. For a pit of the width stated, it should be 3 yards wide, which will be sufficient to cover the pit from the top of the paling at the back down to the ground in front. It should be tacked on to stout wooden rollers for rolling it off and on morning and evening; and if it is, Pentstemons, Carnations, Calceolarias, &c., can be struck successfully, and the same can be sheltered effectually under the frigi domo during winter. In fact, such a pit is easily made, cheap, durable, and need never be idle all the year round.—J. S.

Early Vegetable Culture.—In front of our plant-houses are several very warm early borders; they are not large, but the soil in them has been specially prepared for early cropping to the depth of 3 ft. or so. In preparing sites for early crops this labour is of the most profitable kind; as when once thoroughly done annual top-dressings afterwards will sufficiently maintain fertility, with, of course, deep stirring of the soil. These warm borders are devoted early in the season to such crops as Potatoes, Cauliflowers, Lettuce, Horn Carrots, and Radishes, making a sort of rotation with each other annually. We usually commence digging Potatoes from these borders in the open air by the middle of May. Such borders are very easily protected, which in the case of Potatoes with us is accomplished in this way: stout Ash or Hazel rods have their thick ends planted firmly in the front of the border; they are then bent over and the other ends secured under the wall-plate of the house. A sufficient number of mats is sewn together, so that two pieces will cover all up; they can easily be covered or uncovered in a few minutes, and in windy weather a tie or two makes all secure.—E.

Jerusalem Artichokes.—For ten or twelve years I have had very good crops of artichokes from a piece of ground on which nothing else will grow, it being so much sheltered by high palings and my neighbour's trees. The soil is good, light and deep; the only manure I have used is garden refuse. This year all the artichokes, instead of being round, have run very long, thin and stalked. In one spot, however, I dug up some of the largest I ever saw, 9 in. long and 2 in. diameter, weighing 10¼ oz.—J. H. D.

Sowing Parsnips.—These require a deep well-pulverised soil, in which the manure has been deeply buried, or one that has been so highly manured for a previous crop as to require none. If freshly manured, the roots will be coarse and much forked. The Hollow Crowned and Student are the best varieties, and of these seed should be sown in drills 1½ in. deep early in March; the drills should be 15 in. apart, and the young plants, when large enough, should be thinned out to 6 in. asunder. For this, as well as for all other growing crops, frequent stirrings of the surface of the soil between the rows are exceedingly beneficial.

Sowing Carrots.—The early French Horn should be sown at once on a warm border in drills 1 in. deep and 9 in. apart. It is not necessary to thin this crop much, as the moment the young plants are as large as one's finger the largest may be drawn for use. The main crop of James's Intermediate and Altrincham may be sown early in April on land that has undergone thorough cultivation. If manure had been used it should have been of the lightest possible description and dug in some distance below the surface. In places subject to the maggot, dress the land in winter with salt, lime, and soot. The two latter may be employed liberally, but salt must be used more cautiously—½ lb. to the square yard will in most cases be sufficient. I have occasionally used much heavier dressings, but we ought to know something of the character of the soil on which we are operating before applying it in excessive quantities. On heavy land, where there is a difficulty in obtaining good Carrots, after the ground has been got into good condition in April set the rows from 13 in. to 15 in. apart, then make holes with a crowbar 6 in. asunder along the rows; let the holes be 15 in. deep and 3 in. in diameter at the top; fill them up with any light, rich compost (two or three barrowsful will go a long way), drop three or four seeds in the centre, and cover lightly. When large enough to select the strongest, thin out the young plants to one in each hole. This is an excellent way to secure a good crop of clean, well-shaped roots, and the work is not so formidable as it looks.

Salsafy.—This root has, when cooked, a strong flavour of oysters, so much so as to have acquired the name of the Oyster plant. It is not much grown in small gardens, but a row or two of it will not occupy much space, and will furnish a desirable change occasionally in the way of vegetables. The roots are very apt to grow forked unless the manure be buried deeply. The best way is to open a trench 18 in. deep, place the manure at the bottom, return the soil, and sow the seeds in a drill 1½ in. deep, exactly over the manure, so as to tempt the roots to run straight down to it. The drills may be 1 ft. apart, and the plants should be thinned out to 6 in. asunder. The first week in April is the best time to sow Salsafy, which if sown too early is apt to run to seed. The roots keep best in the ground in the same way as Parsnips; and, if a little dry litter be placed along the rows on the approach of frost, they may be lifted as required.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 15.—Sowing Balsams, German and Ten-week Stocks. Putting in cuttings of Coleus, Fuchsias, and Verbenas. Potting off spring-struck Verbenas and Heliotropes. Levelling down Celery trenches, and getting the ground ready for Peas. Re-making Mint beds. Thinning out and cutting back Ivy on walls. Sticking early Peas, and giving them a little earthing up. Mending Box edgings.

March 16.—Sowing Long Pod and Windsor Broad Beans. Potting off Cucumbers and Melons. Putting in cuttings of Alternantheras and Mesembryanthemums. Turning over manure for Celery, having previously mixed it with salt and soot. Giving the surface of the Carrot and Beet ground a dressing of soot, and preparing it for drilling.

March 17.—Sowing Snow's Winter White Broccoli, Brussels Sprouts, and Wallflowers. Shifting Tomatoes and Capsicums. Pricking out Celery and All the Year Round Lettuce. Planting the main crops of the following sorts of Potatoes: Snowflake, Breadfruit, Main Crop, Giant King, Model, Schoolmaster, Porter's Excelsior, Paterson's Victoria, King of Potatoes, and Perfection Kidney.

March 18.—Sowing Cucumbers and Melons. Planting out autumn-sown Cauliflower; also a few Brown Cos Lettuces. Preparing ground for new Seakale beds, and also for Globe Artichokes. Earthing up Potatoes in frames. Forking over the ground amongst Cabbage plants.

March 19.—Thinning Grapes and tying down young shoots in early Vineries. Looking over Cucumbers. Getting netting and other coverings over Peach trees for protection. Looking over fruit room, and removing any fruits that are decaying. Renovating linings round manure frames. Weeding Box edgings and gravel walks. Dividing and re-making Herb beds

March 20.—Cleaning up the pleasure grounds, and rolling down all gravel walks that require it. Covering up Seakale beds. Looking over Pelargoniums; picking off all dead leaves and stopping the shoots where required. Clearing off borders, giving them a dressing of soot, and forking them up ready for seeds.—W. G., *Dorset.*

Glasshouses.

Borders in which plants are growing should be lightly forked up, and if the soil is exhausted a dressing of loam, leaf-mould, rotten manure, or good peat may be added, according to requirements. Some plants need more water than others, and in such cases neatly-formed basins of soil should be made around them, so as to retain sufficient for their wants without overflowing. This is an excellent time for transferring plants from pots to conservatory borders,

and in doing so disentangle and spread out the roots as much as possible. This may check growth for a time, but eventually, other circumstances being favourable, plants so treated will succeed better than such as are planted with the roots coiled up in a ball. Camellias, Rhododendrons, Acacias, &c., when grown in pots are more under control than such as are planted out; but the latter are generally the most satisfactory, both as regards growth and bloom. Clianthus puniceus, if too thick, should have its shoots thinned out a little, so as to give sufficient light to the flowers. Passion-flowers should be pruned well in, and the soil in which they are growing should be thoroughly saturated with water, so as to induce them to start freely into growth. Cut in the branches of Habrothamnuses. Several of the free-growing Fuchsias are well suited for conservatory roof decoration or that of pillars, especially when planted out in borders. If trained to the rafters from the middle of April until they are completely denuded of side branches in the end of October or November, or for the purpose of resting them and admitting light to the other inmates of the house, they form objects of interest, being richly laden during all that time with both flowers and foliage. Cuttings of Coleus struck early should be potted as they require it, pinched at the third joint, and the plants be kept near the light. Iresines form attractive summer objects in conservatories; therefore, treat them like Coleuses. The general stock of Begonias should now be potted and started into growth. Caladiums started in small pots should be shifted into larger ones before their roots become entangled. Continue to force Lily of the Valley; place the plants that have been forced under the stages of the greenhouse for a time, and after that plant them out, where, if they be well cared for, they will in two years make good plants for forcing again. Some plants of Lilium auratum should be introduced into the greenhouse for blooming in May. In making up baskets for suspending in the conservatory, keep them in a warm house until they are in active growth, when they may be gradually hardened off, so as to withstand the cooler temperature to which they are to be subjected. Keep up a young and healthy stock of Fuchsias, Heliotropes, Petunias, and other plants for early blooming; those treated more hardily flower later.

Chrysanthemum cuttings struck at the end of the year will by this time be well rooted and hardened off; they should be at once moved into 6-in. pots, using ordinary loam made rich with one-third rotten manure and leaf-mould in equal proportions, to which a little sand has been added. There is no grosser feeding plant in cultivation than the Chrysanthemum. To grow it successfully the soil must be rich, and in its early stages it must never be allowed to become pot-bound, for if this occurs, no after-treatment will ever impart to the plants their wonted vigour, as the stunted condition the roots get into when confined in little pots has the effect of prematurely hardening the shoots. It will be necessary to decide upon the desired state of the plants. In most cases it is advisable to adopt two or three forms, but the flat, Mushroom-headed fashion should never be followed. The most generally useful for decorative purposes are plants with a dozen or more shoots, ultimately trained with just as many sticks as will support them. All plants intended to be grown thus should, at the time of potting, have the points pinched out to induce them to break several shoots. This shape will be found the most suitable for the medium-sized, freest-flowering of the large varieties, and also for the Pompones. Many of the large kinds that produce the finest individual blooms are not capable of being seen in their best form if many flowers be allowed to each plant; for ordinary purposes six or eight will be enough on each; for growing in this way the plants must be also stopped now to cause them to form three or four shoots. Those who are disposed to attempt the production of a few of the finest flowers may do so by only allowing each plant in a 9-in. or 10-in. pot to carry from one to three flowers. These will be found very effective when in bloom if arranged in the greenhouse amongst the dwarfer growers, relieving the even surface, which is justly held objectionable in a stage filled with Chrysanthemums of nearly the same height. To grow them in this way the young plants now potted should not be stopped at all, but simply trained to a single stem all through the season, allowing it to branch out in summer near the top to as many shoots as it is destined to carry flowers. Chrysanthemums are frequently seen but mere shadows of what they are capable of being produced; yet they are easily managed, and well repay a little extra attention.

Herbaceous Calceolarias that have now filled their pots with roots and are pushing up their flower-stems will have their blooming capabilities much increased by the continuous use of liquid manure; these should be in a warmer place than the Cinerarias, and a vigilant look-out kept to see that insects do not get established upon either of them.

Pelargoniums.—The earliest-blooming, large-flowered, and fancy Pelargoniums will now be showing their flowers; and as the roots by this time will have taken full possession of the soil, they should be supplied with manure water once or twice a week. If attention in this matter be not paid to these plants, there is a difficulty in keeping the foliage of that dark green healthy hue which so much enhances their appearance when in flower.

Flower Garden.

Auriculas.—These are now making rapid growth. The trusses are showing up freely through the varied and beautifully powdered foliage. It is an anxious time, especially for the exhibitor, who has to get his flowers in perfection by a certain date—about the end of April; and, unless he is well acquainted with the character of the different varieties, a mistake may easily be made. Not only do some varieties take much longer to perfect their trusses than others, but a great deal depends upon how the trusses come. Sometimes they can be seen deep in the centre of the plants in autumn. These take a long time to come to perfection; the flowers will probably not open until April. Another plant will have a large centre which will not show any signs of a truss until March, when, as if by magic, a leaf or two is unfolded, and lo! a fine truss is exposed to view, with the flowers almost expanded, and probably in advance of that formed in autumn. As a rule, the earliest-formed trusses produce the finest flowers. The plants must not now be allowed to suffer from want of water, but it must be applied without wetting the leaves; the fine mealed foliage is easily injured; a shower of rain is most disastrous. The lights may be removed altogether in fine weather, but no rains or cold winds should have access to the plants. The small offsets potted in the autumn should now be shifted into larger-sized pots; the little plants will make rapid growth, and form fine plants by the next blooming time.

Herbaceous Phloxes.—The Phlox is a gross feeder, and never succeeds well unless the ground is deeply trenched and well manured; this ought to be done in the autumn, so that the frosts of winter may pulverise the soil, and it ought to be turned over two or three times. If all the cuttings have not yet been put in, see that they are inserted at once, as previously recommended. Cuttings put in early, and rooted in a gentle bottom-heat, are very useful for flowering in pots in the autumn. The plants must be potted on and carefully attended to, else they will not flower until the second year.

Tulips.—These are now above ground, and the surface of the beds has been covered over with some rotten frame manure. Nearly all sorts of plants succeed better in light soil when the surface of the ground is mulched; in that case water can be applied without causing a crust to form on the surface, and when water is applied it does not evaporate rapidly. Of course, it is not necessary to apply any water to the Tulip beds at present. It used to be the practice of the old growers to cover their beds early in the spring, and it may be necessary to do so in cold wet districts; but the plants do not sustain any injury from the weather in dry, well-drained districts.

Pansies in Beds.—The surface of the ground should now be stirred with a pointed stick, and all weeds should be carefully removed with the fingers. If there be sufficient space between the plants, it will be as well to run the Dutch hoe through amongst them. Mulch the surface of the beds with rotten manure.

Pinks.—These require treatment very similar to that given to Pansies. Blank spaces should be filled in with plants that have been saved in pots and wintered in a cold frame. There are a few varieties that will not do well in the open ground during the winter, and if they should be scarce it is better to save them all in pots, as in the case of Carnations.

Gladioli.—These should now be planted out for the main bloom. Those planted out about the middle of March or towards the end of that month generally succeed the best.

Dahlias and Hollyhocks that have been re-potted into 5-in. or 6-in. pots should be placed in frames and have plenty of ventilation, removing the lights altogether in fine weather. Hollyhocks will not suffer from frost, but the Dahlia is exceedingly susceptible to it. Dahlias are not often injured by insect pests, but thrips and red spider injure the Hollyhocks. Syringing and fumigating with Tobacco-smoke is the best way to destroy them. Those who grow these useful autumnal flowers for exhibition will have by this time the ground in good condition. It ought to have been trenched and well manured in the autumn, and in fine weather the surface may be forked over to the depth of 3 in. or 4 in. Hollyhocks may be planted out in the course of a week or two.

Sweep and roll lawns and walks as soon as the weather becomes favourable. Judiciously prune evergreen shrubs such as Aucubas, Hollies, Bays, Box, Yews, Portugal and common Laurels, Junipers, Thujas, Cypresses, Ivies, &c., which may be outgrowing the spaces allotted to them, keeping symmetry and gracefulness of form as much as possible in view. The knife is better than shears for such an operation, the latter being apt to mutilate the leaves.

Herbaceous Borders.—Most of the plants will be aboveground and the mulching material put on early in the winter ought to be dug in. For this work use a fork in preference to the spade. Should the grass need edging it can be done at the same time, thereby imparting to the whole a neat appearance. Be very careful not to disturb the roots of any kind of Lilies, as they, more than most subjects, are impatient of any interference at this season. Summer and autumn-blooming herbaceous plants, such as Phloxes, Asters, or any flowers that exist in large masses when the season is considerably advanced, it will be well to divide at the present time, as by this means their roots will be placed within reach of fresh soil, which will strengthen them and enable them to bloom better. It is necessary to keep well back in the border tall-growing plants of this description; but as far as possible avoid planting them where the ground is occupied with deciduous tress, as herbaceous plants have but a very poor chance of success under these circumstances; yet, as in such situations it does not look well to have the ground bare, there is nothing better suited than the strongest tall-growing varieties of Michaelmas Daisies and Golden Rods, to assist which in such positions an extra liberal dressing of manure should be given every spring, digging the ground with the spade a full spit in depth, which will cut off obtruding roots, and for a considerable portion of the summer spare the plants being affected by them. Any choice plants that are subject to the attacks of slugs will be benefited by 1 in. of coal-ashes being placed round the collars of the plants, which, though it will not altogether prevent the slugs from attacking them, will, in a great measure, hinder them from harbouring under the plants.

Vegetables.

A continuous supply of good vegetables through the season much depends upon the attention during the next few weeks in putting into the ground the numerous seeds that require it. The whole of the Potato planting should be brought to a close before the end of the month. If the seed has been prepared as advised it will be in good order. In planting the general crop there are two courses to follow: either place the rows sufficiently far apart to admit the winter Broccoli, Cabbage, Brussels Sprouts, &c., being afterwards planted between the rows, or put the Potatoes far enough apart to ensure their well-being without anything else between them. In the former case the rows will require to be 3 ft. asunder; in the latter 2 ft. to 2 ft. 3 in. will be sufficient. The single-cropping system is preferable, as when double-

cropping is resorted to the winter vegetables never do so well, and in many cases are too far apart when the Potatoes are removed. On the score of economising space, this double-cropping is evidently more loss than gain.

Sowing Seeds.—Sowings should now be made of Cocoa-nut and Enfield market Cabbage, green Curled Savoy, Walcheren and Early Snowflake Cauliflower, and Autumnal Giant Cauliflower. Cover the seeds with red lead, to protect them from birds. Successional Broad Beans and Peas will now require putting in. Excepting where the vegetable ground is limited, and there is a difficulty in procuring Pea-sticks, there is nothing to equal the tall Marrow kinds for furnishing a large and continuous supply, which does not come in altogether as the dwarfer-growing varieties do. Where the tall sorts of Peas are grown, and the ground is rich and in good condition, they will require 5 ft. 6 in. space between the rows; this will be sufficient, and better than sowing farther apart with Broccoli or Celery between, as is sometimes done; such double-cropping being here again no advantage, for the Celery, Broccoli, &c., so grown never has the necessary strength and vigour to withstand the winter that they have when grown by themselves. A row of Spinach can always be grown without any disadvantage between Peas so planted. Amongst winter vegetables there is nothing that is of more real use than Brussels Sprouts. To grow them well, the seed must be sown not later than the third week in March, so as to get the plants a good size early, planting them out where they are ultimately intended to grow as soon as they are large enough.

Aralia japonica.—This is a fine-leaved plant, perfectly hardy in the south, but requiring shelter in northern districts. When grown in groups on lawns or in shrubberies it has a noble appearance. It also makes an excellent window plant; its leaves being smooth and glossy, they can easily be kept clear of dust. It requires rich soil and plenty of water to grow it well, and when in active growth a little soot-water or liquid manure greatly improves the appearance of its leaves by rendering them large and thick, and of a dark glossy green colour.

Aralia japonica, a hardy plant for the garden or window.

Caladiums for Rooms.—The beautifully-diversified markings of the leaves of Caladiums, combined with their being plants of the easiest possible culture, renders them general favourites. Plants of them in small, say 6-in. pots, grown in not too much heat and near the light, without more shade than is absolutely necessary to keep them from scorching, may be used with advantage for table or indoor-vase decoration. Yet even when thus especially prepared for indoor work they must not be kept too long out of heat, or they will suffer. For this purpose loam is preferable to peat to grow them in, as it induces a more robust habit of growth. Start the plants into growth any time after Christmas, giving them a good light position in a house or pit where they can receive 60° or 65° night temperature, with 10° more by day, ; attend to them well with water, and when they have filled their pots with roots they will be benefited by an occasional application of manure water; syringe them every evening overhead, in order to keep them clear of red spider, which is their worst enemy. As the season advances, gradually inure them to a fair amount of air on all favourable occasions. This will render them less likely to sustain injury when removed from their growing quarters. Towards autumn, when they show signs of going to rest, gradually withhold water, and keep the soil almost dry during their season of rest; but the roots should never remain long in a lower temperature than 60°, or they are liable to rot. Caladiums are increased freely by means of cuttings taken off with a heel, or by bits of the roots containing buds.

ANSWERS TO QUERIES.

1578.—**Flower Shows for Children.**—In the City of London the plants most commonly grown by the denizens of narrow streets and courts for exhibition at the City Show are such as Fuchsias, Pelargoniums (or better known as Scarlet Geraniums), Onion plant, Creeping Jenny, common Musk and Harrison's Musk, Ferns of hardy kinds, the Green Coleus, better known as the Nettle plant, Mignonette, a few common annuals, Houseleeks, Carpet Sedums, Balsams, Petunias, and a few other common things that are fairly hardy and will do well with a moderate amount of sunshine. Assuming that it is proposed to promote a flower-show in a town for children, the first regulation should be for the purpose of ensuring that the plants and flowers are the property of and grown by the children. Thus a rule should be made that all plants exhibited should have been in the possession of the exhibitor for a period of at least two months, and this rule should be backed up by visitation of the children's homes to see that they have the plants in their possession. Some limit might well be put upon the size of the pots in which the plants are grown. If wild flowers are shown, they should be in bunches of sorts as far as possible correctly named, so as to make their collection of an educational character. The chief regulations for the guidance of the promoters will be found in fixing the hours for the receipt of plants, for the regulation of the judging, for the opening of the show to the public, for the number of tickets to be given to each exhibitor, the time of closing the show, the prices of admission to be paid, and so on. All these are most simple and general, and will readily occur to any intelligent person. Much good may be done by the distribution amongst deserving children of suitable plants in pots, also some common annual seeds, and, not least, of a small quantity to each of some fair potting-soil, as the obtaining of this in a crowded city becomes almost an impossibility. —A. D.

1532.—**Annuals and Perennials for Bouquets.**—*Perennials*—American Cowslip, Dog's Tooth Violet, *Pyrethrums, Pinks, *Carnations, of all varieties, *Aquilegias, Larkspurs, Lilium candidum, Lilium chalcedonicum, Martagon Lilies, Anemone japonica, *Chrysanthemums, *Pompones, *Phloxes, Polyanthus Narcissus, *Pheasant's Eye Narcissus, *Tulips, *Hoteia japonica, *Spiræa filipendula, *Spiræa palmata. For small bouquets—*Snowdrops, *Lily of the Valley, *Scilla nutans, London Pride, *Primrose, single and double, *Pansies, *Sweet Violets, Border Violas, *Alpine Auriculas, *Wallflowers. In addition to these the smaller side flowering shoots of the following are useful:—Yellow Antirrhinums, Canterbury Bells, single and double, White Foxgloves, and Sweet Williams. *Flowering Shrubs*—*Jasmine, white and yellow, Jasminium nudiflorum, Daphne in variety, Double-flowering Cherry, *Roses, *Persian Lilac, Laburnum, *Hawthorn in variety, *Honeysuckles of all kinds, *Clematis, *common Broom. *Hardy Annuals*—*Nasturtiums, *Coreopsis, all kinds, Lupins, Mignonette, Eschscholtzia crocea flora-pleno, *Sweet Peas. The annual Chrysanthemums are also very showy, but many people object to the smell of them. *Half-hardy Annuals*—*Phlox Drummondi grandiflora in variety, *Zinnia elegans in variety, *Indian Pinks, *Dianthus Heddewigi, single and double. Those marked (*) are the most useful.—J. D.

1566—**Propagating Tacsonias.**—Tacsonia Van Volxemi can be propagated either by means of seeds or cuttings. To raise it from seed, select a well-ripened fruit in the autumn; cut it open, take the seeds out and mix them with sand, and well rub them together to clear them of the pulp. Lay the seeds thinly on paper until quite dry, when they can be stored away in a dry place until required for sowing. In February or March sow the seeds in pots of light sandy soil and place them in a warm greenhouse or gentle hot-bed; they will germinate in about four or five weeks. When the plants are large enough to handle, pot them into 3-inch pots, using any light rich soil. As soon as the roots fill the pots shift them into 6-inch pots. They will make good plants suitable for planting out the following spring. To grow the Tacsonia from cuttings, select half-ripened shoots of moderate growth, such as are firm and not hollow; cut into cuttings about 3 inches long, insert them into well-drained pots of sandy soil made moderately firm. Plunge the pots into gentle bottom-heat and cover them with a bell-glass. As soon as rooted treat them the same as the seedlings. Plants grown from cuttings will come into flower quicker than those grown from seeds.—WESTON-SUPER-MARE.

1503—**Cost of Greenhouse.**—It is very difficult to give even the probable cost of a greenhouse with such an indifferent knowledge of the circumstances; and the simplest way would be to get some local carpenter to give an estimate, as cost of labour and material differs greatly in various localities. Taking a general basis of prices, it is probable that the cost would not be less than £10. As the house is needed only for Ferns, it might be of less height than is needed for plants; and the pathway somewhat sunken inside will render height less necessary. Shade should suit the Ferns very well, and it would be a good arrangement to build up the front portion inside in the fashion of rockwork, and plant it with moderate growing Ferns and Lycopods, whilst the stage over the flue may be reserved for Ferns in pots.—A.

1536.—**Birds and Seeds.**—A roadway about 20 ft. wide divides my garden from a farmyard where there are always three or four haystacks, besides which the house and premises have all thatched roofs. Nothing could well be more favourable for harbouring sparrows, yet I find, after trying several remedies, nothing so effective and simple as a single line of black thread for keeping birds from seeds. Place a somewhat stout stick at one end of the row (say for Peas), and a similar stick at the other, with one or two in between, as you may think fit; then stretch a single black thread along from one end to the other about 2 in. or 3 in. above the ground. For a row of Peas you would want two rows of thread, about 6 in. apart. For beds of seeds the rows of thread should be 9 in. apart over the whole bed. The thread being so fine, birds seem to have a horror of getting entangled; whereas with string or netting they will often sit on it or fly through.—F. X.

1583.—**Orange Trees in Boxes.**—If wooden boxes are preferred, there is nothing better than the best red deal. The inside might be charred by smearing some Stockholm tar over it, and setting fire to it, and the outside well painted. Boxes are sometimes made with movable sides, to facilitate replanting should it be necessary. The best time to transfer the plants to new boxes is in April, as then, by keeping the house close and moist, new roots will be made immediately. The best soil is turfy loam two-thirds, old manure one-third; and a few crushed bones might be added, say about a peck to four or five bushels of soil. The boxes must be well drained, and the soil rammed in firm. See that the old balls are in a moist condition when replanted.—E. H.

1533.—**Trailers for Window Boxes.**—Of plants to form a drooping edging for a window box the best raised from seed are Convulvulus minor and dwarf Tropæolums, both of which will fall over the front and droop if planted near the edge. Also Mignonette, Nemophilas, Silene pendula, and Eschscholtzia crocea. Of hardy perennials, the Creeping Jenny, Musk, and Campanula Barralieri, and the half-hardy drooping Grass, Isolepis gracilis, one of the most pleasing of all plants for the formation of drooping edging.—A.

1560.—**Management of a Window Case.**—It is scarcely probable that a Passiflora, which is a strong rank grower, would do in a window case, but such moderate creepers as Thunbergias, Tropæolum, Lobbianum, in pots, also Lophospermum scandens, may. The Thunbergias are charming plants to suspend in pots from the top of the case, whilst the more robust climbers should be trained around it. One of the most fitting climbers for a Fern case is the climbing Fern, Lygodium scandens, which forms a pleasing framework for other Ferns if it be neatly twined round twigs or stout string.—A. D.

1561.—**Steam in Forcing Frame.**—Probably the best plan to exclude superabundant steam from a frame would be to put over the slates at the bottom a thin layer of turf, with the Grass downwards It is a common practice to do this on a hotbed beneath newly-planted Cucumbers when there is danger from strong bottom-heat. A thin layer of turf on the slates, and on that 1 in. of Cocoa-nut fibre refuse, on which the pots should be placed, will doubtless exclude all injurious steam, and yet admit the needful heat.—D.

1531.—**Roses for Lancashire.**—Baronne Prevost, Captain Christy, Dupuy Jamin, Charles Lefebvre, General Jacqueminot, John Hopper, Jules Margottin, La France, Madame Bole, Mons. Paul Neron, Souvenir de la Malmaison, Gloire de Dijon.—E. H.

1523.—**Manuring Lawns.**—If ordinary manure is objectionable give a good dressing of soot; 1 bushel to the square rod will not be too much. Nitrate of soda is a very stimulating application in moderate quantities, but it is not lasting enough for a lawn; and the same must be said of all artificial manures. Bone-dust ground small is an excellent top-dressing. If the roller is used frequently it will press the small particles of bone into the turf, out of the way of the mowing machine.—H.

1537.—**Cherry and Pear Trees not Fruiting.**—The buds probably do not ripen well; the soil is too stiff and rich for Cherries. Work in some lime rubbish or old mortar from old buildings among the roots towards their feeding extremities. Leave the Pear tree unpruned for a year or two, merely thinning the branches, not shortening them; probably this will have the desired effect. The new life or force imported by extension will make it fruitful.—E.

1580.—**Fruit Trees for Yorkshire.**—I should recommend either a good Pear, such as Marie Louise or Duchesse d'Angoulême, or else a good Plum—say the Golden Drop or Transparent Gage.—E. H.

1565.—**May Flower.**—Epigda repens, heath soil under bushes; 6 in. to 12 in. high; flowers in April.—M. M.

1577.—**Staging for Small Greenhouses.**—Nothing makes a better stage for greenhouse than slates. My house is 20 ft. by 9 ft., a stage on each side 3 ft. wide, with 3-ft. path; each slate is 3 ft. by 2 ft., which cost 1s. each, upon which I put 3 in. or 4 in. of Cocoa-nut fibre, and I can say with confidence that any greenhouse plant will grow on it. In summer it gives moisture; in winter it prevents the too rapid evaporation when the fire is burning. Geraniums and Fuchsias grow remarkably well—in fact, they make roots 2 yards long—on the slates. —AMATEUR OF TWENTY YEARS.

1529.—**Hunt's Sweet William.**—Sow now in very slight heat, and prick out the plants into a box when they have made three pairs of leaves: Plant out where they are to flower in April, after being hardened off. Or sow in August in the open ground, and put the plants out where they are to flower in September. Sweet Williams are extremely hardy. I have had some out-of-doors in a pot through the severe frosts of last December; and some of them planted in the first week in January in an exposed border are just starting into growth. A light, rich soil suits them best. Old hotbed manure or leaf-mould is the most suitable dressing for the soil.—J. D.

—— Seed of Hunt's or indeed any kind of Sweet William may be sown in the open air through March and April in light soil thinly; the young plants pricked out into good free working soil about 12 in. apart, when large enough to be so treated. Such plants will develope into large bushes, carrying the next season several heads of bloom. Any good garden soil will bring flowers of fine quality and of good size.—A.

1567.—**Worms in Garden.**—Get a shovelful of air-slaked lime, put it into a bucket with four or six gallons of water, stir well, and let it settle. Use the clear water only. Do this on three or four consecutive nights, and you will soon clear the worms. The lime will not harm lawns or plants in the beds. A little soot mixed in it would be an advantage.—BRADFORD.

—— Turn a brood of young ducks into the garden they will soon thin down the worms. Ducks will not injure plants until they are about a third grown; and up to that time they are invaluable for destroying worms. If the garden is enclosed, buy a couple of peewits; clip one wing, and turn them into the garden. They are even better than ducks for getting rid of worms.—G. A. PASSINGHAM, *Cambridge*.

—— I should advise using the refuse charcoal employed in making steel. It has been employed with success on croquet lawns by spreading it about November, and it disappeared by spring. I believe it can be obtained in Sheffield at a cost little beyond the carriage.—A YORKSHIREMAN.

1516.—**Weedy Lawns.**—I was troubled with a weedy lawn, and I got 2d. worth of sulphuric acid, and with a glass out of a broken thermometer dipped in the acid I just touched the centre of each weed, no matter whether Dock, Dandelion, or Plantain, and it withered in a few minutes, and could be picked off and taken away never to appear. After going over a lawn in that way two or three times you will completely clear it. Care should be taken not to use too much, or the lawn Grass will be also destroyed.—BRADFORD.

—— Coltsfoot is a very coarse-growing, large-leaved perennial and should be killed outright by constant mowing. Probably it is Crowfoot or the dwarf Buttercup (Ranunculus bulbosa) that is meant, as that is a great pest to lawns, and mowing does not kill it. There is no other cure but pulling out by the roots, and persisting in the work until the weeds are extirpated. Watson's Lawn Grass has a good reputation for killing weeds if sown over lawns and well brushed into the ground.—A.

1582.—**White Flowered Chrysanthemums.**—Mrs. George Rundle, Mrs. Forsyth, Beverley, White Venus, Mrs. Heale, Princess of Teck, Elaine, Ethel, Fair Maid of Guernsey, Lady Margaret, Miss Margaret, Fleur de Marie. *Pompones.*—Reine de Anemones, Mademoiselle Marthe, White Trevenna.—J. D.

—— For ordinary greenhouse culture the following are equal to any:—Mrs. George Rundle, White Venus, White Eve, Beverley, and Virgin Queen (Incurved); Fair Maid of Guernsey, Elaine, and Ethel (Japanese); White Christine (Reflexed); Fleur de Marie or Lady Margaret (Anemone); Madam Marthe and White Trevenna (Pompons). If individual show blooms are required, the last five must give way to Empress of India, White Globe, Mrs. Heales, Princess of Teck, and Mrs. Halliburton: These latter require high culture, and must be established early.—N. D.

Caladium.

—— Of Japanese or tasselled kinds some of the purest white flowers are Elaine, Fair Maid of Guernsey, and Jane Salter; of large-flowered kinds, White Queen of England, Mrs. George Rundle, White Globe, and Princess of Teck; Anemone-flowered, Virginale; and of the smaller-flowered sections, Marabout, White Trevenna Mdlle. Marthe, and Madame Domage. All these come very pure under glass.—D.

1492.—**Maiden-hair Ferns not Growing.**—I have beautiful and luxuriant Maiden-hair Ferns growing in pots in an ordinary living-room with a bay window. I never let them get quite dry. Perhaps "A. E. C." has gas in her rooms; if so, of course glass is necessary.—M. L. B.

1496.—**Gardening in Towns.**—I grew Carnations for many years in a town garden very successfully. Auriculas will also thrive very well in a confined space, and enjoy being mulched with tea-leaves occasionally.—M. L. B.

1517.—**Durability of Cyclamens.**—With good culture Cyclamen roots have been kept to bloom freely, even at twelve years of age, but so easily are fresh roots raised from seed that the old ones are hardly worth the trouble. When the plants have done blooming they should be placed in a frame not exposed to the full rays of the sun, kept cool and moderately moist, and not allowed to lose their leaves nor to go entirely to rest. They should flower freely in any ordinary greenhouse now.—A.

1518.—**Hotbed Frame.**—A useful size for a single light frame for a hotbed is 6 ft. in length and 4 ft. in width; the sides and ends alike made of 1½-in. boards; the back end 20 in. in height, and the front end 12 in. high, the top edges being bevelled off to match the slope of the sides, which should, of course, be the same height behind as the back is, and in front as the front end is. On the outside upper edge of the sides should be nailed a stout strip of wood, the depth of the thickness of the light, to keep it in its place and prevent the wind from getting beneath it. In each of the four corners there should be fixed a triangular-shaped piece of quartering, as this nailed to the frame gives the corners much additional strength.—A. D.

1568.—**Manure for Potatoes.**—Leopoldshal kainit and superphosphate is recommended in equal quantities as a manure for Potatoes (5 cwt. of the mixture to the acre), but I cannot say where the Kainit may be obtained. Perhaps some reader will kindly inform me. Kainit contains a large percentage of potash salts, and would therefore be an excellent substitute for wood ashes.

1508.—**Treatment of Dracænas.**—The tops of lanky Dracænas taken off and put in now as cuttings in rich turfy sandy soil, and in a strong bottom heat, should strike freely. The bottoms will then, if put into warmth, break and throw out side shoots, and these again may be taken off and converted into cuttings. Young plants are even better coloured and more handsome than old ones.—D.

1509.—**The Cape Pond-weed.**—The Cape Pond-weed, although classed as a greenhouse plant, and even doing well under certain favourable conditions in this country in the open air, yet really needs more warmth than is just now perhaps afforded in an ordinary greenhouse. As the sun heat increases the plant will probably improve, but much depends upon the peculiar conditions under which it is being grown.—A.

1527.—**Gladiolus Brenchleyensis.**—This will succeed well in pots. Plant one bulb in a 6½ in. pot or three bulbs in an 8-in. pot. Pot them about 2 in. deep in light rich soil, two parts loam, one part rotten manure or leaf-mould, with a sprinkling of silver sand. Place the pots out-of-doors, and cover them with Cocoa-nut refuse or ashes until the plants appear above ground, when they may be removed to a frame or greenhouse, where they should have plenty of air to prevent them becoming drawn. As soon as the flower-spikes appear water the plants twice a week with weak guano water.—WESTON-SUPER-MARE.

1514.—**Moss in Cool Fernery.**—Mosses will much more freely attach themselves to damp unwashed brickwork than to a lime-washed wall. The simplest way to secure a Moss covering is to build into the wall a quantity of projecting pieces of tile, and on these projections place suitable soil, and into it dibble pieces of such as Selaginella denticulata, keeping it well syringed through the summer season.—D.

1515.—**Mildew in Fern Cases.**—Probably the best thing to do with mildewed Ferns in a Fern case would be to take them out, free them from the soil, dust freely with sulphur, and then remove all the soil in the case; wash and cleanse the case, put in fresh peaty soil and replant. This may extirpate the mildew.—A.

1530.—**Lobelia speciosa.**—Lobelia speciosa seed may be sown at once in shallow pans in fine sandy soil, and be placed in a sunny part of a greenhouse. The seedling plants, when large enough to handle, must be pricked out thinly into other pans or into boxes, and in these grown on and presently hardened off by placing them in the open air ready for planting out about the first or second week in June.—D.

1531.—**Yellow Calceolarias.**—Seed of yellow bedding Calceolarias may be sown at once in pans, the soil being first gently damped; and when the seed is sown a large piece of glass should be placed over the pan to induce quick germination. Such plants may be expected to bloom at the end of the summer and through the autumn.—D.

1532.—**Annuals and Perennials for Bouquets.**—Achillea Ptarmica flora-plena, Lathyrus latifolius, Carnations, Picotees and Pinks, double Pyrethrums, Scabious, Aquilegias, Anemones of Dutch and Japan kinds are a few perennials; and of biennials and annuals, Wallflowers, Indian Pinks, Asters, Stocks, Mignonette, Globe Amarantus, Helichrysums, double Zinnias, Phlox Drummondi, annual Chrysanthemums, and Prince's Feather, a few ornamental Grasses, &c., are but a small number of things useful for bouquets.—A. D.

1502.—**Planting a Rockwork.**—A few flowers mixed with Ferns make a prettier rockery than Ferns alone, unless they are very rare or fine specimens, when, of course, they do not require any setting off to advantage. Any little creeping plants—such as Creeping Jenny, Ivy-leaved Toadflax, and different kinds of small Ivy, look better between them than the dry soil. Tufts of Wood Sorrel and wild Anemone dotted here and there ook very charming. Clusters of Snowdrops, Primroses, and Violets, with the blue and white Periwinkles, will make the rockwork still prettier.—TILLY SLOWBOY.

1605.—**Vitality of Seeds.**—I have found that genuine seeds will retain their vitality for more than one or two seasons. Looking over my seed-drawer, I came across two packets dated three seasons back, containing Petunias and Lobelias (very small seeds); and doubtful of their goodness, I sowed them in two pots, and put in slight bottom-heat, with the result that more than one half have come up and are doing well.—G. E.

1523.—**Manuring Lawns.**—I find a dressing of Amies' Chemical Manure (4 oz. to the square yard) an excellent stimulant. It should be applied immediately before rain. If "J. S." gives this a trial I think he will find his lawn greatly improved in a short space of time.—B.

1530.—**Lobelia Speciosa.**—Lobelia speciosa seed should be sown at once in pans or pots of finely sifted soil, covered with a sprinkling of fine silver sand. As soon as the seedlings are large enough to handle, they should be pricked off singly and they will then be ready to plant out in June.—B.

1515.—**Mildew in Fern Cases.**—Open the case daily for about a couple of hours to admit air, and take that opportunity to pick out carefully every piece of mildew. Should the Ferns be of the proper variety for a case they will soon recover their usual health. Should the varieties, however, be unsuitable they will damp off notwithstanding every precaution and care.—HARRY BRIGHTON.

Sowing Vegetable Marrows.—*W. D.*—The middle or end of April will be time enough to sow in a frame. Sow in pots, and get the plants well established and hardened by the end of May; then plant out.]

White Saxifrage.—*Phœbe, Frome.*—Kindly end us some blooms and a leaf.

1664.—**Soil for Araucarias.**—What is the best soil for the Araucaria imbricata?—H. O. [Good rotten turf in which there is plenty of fibre, and sand.]

1665.—**Liquid Manure.**—Will the overflow from a cesspool (house drainage) promote the growth of and be a desirable manure for all plants, more especially Roses?—HOPBLOOM. [If not applied too strong, and it be given to the plants only when they require it. Gross feeding plants will be benefited by it.]

1666.—**Calceolarias in Frames.**—I have some Calceolarias which have been kept in a cold frame during the winter; should they now be potted off and placed in a greenhouse to promote growth? or are they best left where they are?—ANNITA. [If you require them for bedding out the best way would be to transplant them into another bed further apart than at present; or pot them off, whichever is most convenient; do not give them any heat.]

1667.—**Pennyroyal from Seed.**—Can this be raised from seed?—J. A. A. [No; it is always supplied by seedsmen in the shape of plants, which are very cheap.]

1668.—**Giving Air to Frames.**—I have a frame about 5 ft. by 4 ft., and I want to place the back to the wall; ought the top to be loose? or does it matter whether it is hinged, as this will be more convenient to use? Will it make any difference whether the air passes through the high end or under the front?—L. [Hooks and staples are best, as then the light can be removed when necessary.]

1669.—**Ants in Peach House.**—We are unfortunately troubled with myriads of ants in our Peach house, which are devouring the blossom as it opens, as many as three being found busy at work in most of the blooms, and large numbers of these are in consequence strewing the border. We have tried flour of sulphur, tarred twine tied round stems, bird-lime, and dusting with powered hellebore; but none seems to succeed for more than a day or so, and the mischief continues. Can you help us, and that promptly?—J. B. W.

[The following methods of destroying these troublesome pests have been gathered from various sources:—

Bones.—An effectual way of destroying ants in places where boiling water cannot be used is to lay half-picked bones about. These will soon be covered with ants, and can then be thrown into a vessel of boiling water, after which they should be again laid down to attract a fresh batch of victims. By persisting in the use of this trap a house will be completely cleared of ants in a short time; the sooner, of course, in proportion to the number of bones employed.

Carbolic Soap, Brook's Liquid.—Mix a very small thumb-potful of this liquid with a gallon of water, and sprinkle the ants with it. It kills them instantly; it mixes with the water at once without any trouble.

Flower-pot Trap.—Suppose a colony of ants to be commencing operations on a lawn, it is an easy matter to trap them all by placing a large empty flower-pot, with the hole stopped, over it. The ants will build up into the pot, and in a short time it may be lifted with a shovel and carried away and dropped into a vessel of water, which will make an end of them.

Gas Tar.—When ants make a run up the stem of a fruit tree, a line of gas tar all round will put a stop to their progress, and do no harm to the tree.

Guano.—It is not generally known that fresh Peruvian guano will drive ants from any spot, however firm a hold they may have obtained on it.

Putty.—Mr. E. Whitehead, of Blackburn, strongly recommends putty as a cure for ants. His plan is to put five or six lumps of putty in different parts of the house, when they almost immediately become covered with these little pests. He then takes another piece of putty about the size of a teacup, in a rather soft state, and dabs it on the lumps previously laid down, a plan by which thousands may be trapped in a few minutes.

Raw Meat.—A very effectual plan of getting rid of ants is to place raw meat in dishes or vessels of any kind about places which they infest, and, as they prefer that kind of food to any other, they surround it in thousands. Boiling water is then poured upon them, and this, if persistently applied, with the bait above recommended, will in time effect a good riddance.

Treacled Sponge.—In houses and other places where hot water cannot be poured on the soil without danger to the plants, pieces of coarse sponge dipped in diluted treacle will form a most effectual trap. The ants will crowd into the sponges, which should be taken up from time to time and thrown into a vessel of boiling water. Thick treacle spread on pieces of brown paper is also very effective; they get entangled in the mass when sucking it, and their bodies may be swept off the edges at different times till the nests are much thinned of them.

1670.—**Rose Trees on Grass Plot.**—I have a few standard Rose trees on a small grass plot; should I remove the turf a short distance from the bottom of the Brier? or would they grow better with the Grass close to the Brier?—F. W. B. [If you remove the turf you can put a coat of manure round the trees, but if you let the Grass grow close to the trees you must manure them with liquid manure.]

Gooseberry Caterpillar. — *Constant Reader.*—Much information on this subject has lately appeared in our columns.]

1671.—**Briers for Budding.**—I want to bud some Roses this year myself; is it too late to have Briers in now? How should they be planted? and what age should they be? I want to have dwarf or half-standards. Can you tell me a fair price to pay for them, as I wish particularly to try my hand at growing my own Roses. Also, when should the budding take place? On a light, porous soil which Brier would be most suitable?—W. B. [The Briers should have been planted in autumn. If you can get them you might try. They should cost about 3s. per hundred. Choose clean young stems about as thick as your finger, and see that they have nice young roots attached. Bud from July to end of August.]

1672.—**Currants on Wire Fences.**—If black, red, or white Currant bushes are tied horizontally to wires strained along a north wall, 4 ft. high, will they bear good fruit prolifically?—G. DOWNIE C. ELLIS.—[Red and white Currants would do well so situated, but black Currants are best treated as bushes, as they bear fruit only on the young wood.]

1673.—**Sawdust for Starting Plants in.**—Is this good for the above purpose in summer? and does it injure the plants?—J. S. J. [It will do to plunge the pots in, but ashes or Cocoa-nut fibre would be much better or even sand.]

1674.—**Sowing Asters.**—I have purchased some Aster and ten-week Stock seed. I have only a cold frame; when must I sow?—W. D. [Sow a little now, and the remainder early in April; you will then get a succession of bloom.]

1675.—**Growing Cucumbers.**—What is the best soil to start Cucumbers in, and the best heat to maintain (bottom-heat) when growing them from seed? Do they require much water or liquid manure from the first? (I know they do later on.)—J. D. [A bottom heat of 70° to 75° top heat; 5° lower will answer at this season. Water freely, but not with manure water till fairly established. The best soil is that composed of light turfy loam, and well rotted stable manure.]

1676.—**Cuttings of Tomatoes.**—I see cuttings of Tomatoes mentioned on page 791, Vol. I., of GARDENING. Can they be grown from cuttings? Is there any advantage in so doing?—A. L. S. [Cuttings are generally used for early crops grown in pots. They do not grow so rank as seedlings, and come into fruit quicker.]

1677.—**Propagating Gasterias.**—When is the right time to take shoots from a plant of Gasteria lenque? There are now five shoots ready.—T. C. [Turn the plant out of the pot, and tear off the shoots or suckers. Then pot them in sandy loam and old brick rubbish. Do not water them until the soil is thoroughly dry.]

1678.—**Planting Lapagerias.**—I have a lean-to greenhouse, the roof of which is about 11 ft. high, and apt to draw up the plants; I am obliged to cover with some canvas blinds. I wish to try a Lapageria rosea, and should be glad to know whether it will be necessary for me to remove the blinds when it grows up and is trained on the rafters.—T. SWINBURNE. [The Lapageria likes shade in the summer; therefore, the blind could be left on the roof; but why use a blind now—the very thing that makes the plants "draw"?]

1679.—**Keeping Back Dahlias.**—I have some Dahlias which I started 3 weeks ago. The shoots are now 2 in. long. How can I keep them back, as they will want putting out long before they are safe from the frost?—A SUBSCRIBER. [Take off the cuttings and put them in small pots filled with fine sandy soil; plunge them in a gentle hotbed or put them in a warm frame under a bell-glass or hand-light.]

1680.—**Artificial Manure for Grass Land.**—*F. A. L.*—Try Amies' Manure; you will get directions as to quantity to use from the manufacturer.

1681.—**Propagating Lapagerias and Habrothamnus.**—Can I propagate the Lapageria rosea and the Habrothamnus elegans?—J. P. [Lapagerias are best propagated by means of layers or seeds. Habrothamnus elegans may be easily struck from cuttings put in from May to September.]

1682.—**Ivy-leaved Geraniums.**—I have three of these; how should they be grown—against a wall, or in baskets? and ought the tops to be pinched out?—A. L. [They answer well for both purposes. The points may be pinched back to make them grow bushy.]

1683.—**Tradescantias.**—What soil will suit these? also what kind of flowers do they bear?—A. L. [Some of the Tradescantias are hardy, and bear blue and white flowers. Others are greenhouse creepers, and are grown for their foliage; and there are some upright-growing kinds like Draceenas. The former require sandy soil in an open border; the latter, loam or peat and leaf-mould, and a temperature of 50° to 60°.]

1684.—**Varieties of Potatoes.**—I have bought some Magnum Bonum Potatoes and I always thought it was a white kind; but these are red, and I think it is a mistake, as I ordered some Redskinned Flour-ball at the same time, but they are more like white ones; so I thought the papers might have got changed?—NOVICE. [Magnum Bonum is a white kidney-shaped Potato; Redskinned Flour-ball a red-skinned round variety.]

1685.—**Peas for July.**—I want the names of two good Peas ready for use in July. They must be moderately dwarf, good croppers, with well-filled pods of nice-flavoured Peas.—W. B. [G. F. Wilson, Advance Marrow, James' Prolific, and Veitch's Perfection.]

1686.—**Pumpkins Out-of-doors.**—Is there a hardy Pumpkin that will grow and fruit well out-of-doors? Should Marrow and Cucumber blossoms be fertilised? I do not want to grow them for seed, but for the table. Also is the Italian Bush Marrow as profitable as the Old Long White?—W. B. [There is no hardy Pumpkin, but all the kinds will succeed under the same conditions as Vegetable Marrows. It is not necessary to fertilise the blooms of Vegetable Marrows or Cucumbers, except in the case of seed-saving or very early crops.]

Violet Belle de Chatenay. — *Miss W.* — You can procure this Violet from either of the large nurseries in your neighbourhood.

1687.—**Heating Melon Pit.**—Sawdust is not a good substitute for bark, as it is devoid of any fermenting property. Heating by hot-water pipes is the best suited for Melon pits, or if these are not practicable flues would answer well, and stable manure and leaves mixed make excellent material.

1688.—**Fruit Trees for Sunless Wall.**—*Fauna.*—The Morello Cherry is the most satisfactory fruit for growing in such a position, though some kinds of Plum, such as Reine Claude de Bavay, Kirke's Purple Gage, succeed tolerably well, as also do Red and White Currants for late use.

1689.—**Growing Tomatoes in Frames.**—(*Holly Bank*).—A fresh supply of manure is not necessary for growing Tomatoes. Raise some plants from seed sown in a week or so, and grow them on into as fine plants as possible. Then plant them out in good soil in the frame about the end of April.

1690.—**Standard Roses on Grass Plots.**—I have some standard Rose trees on a small Grass plot. Is it necessary to remove the Grass a certain distance round the Briers in order to better promote their growth?—F. W. B. [Not if the Roses are in good health. Give plenty of manure water when they commence to grow.]

1691.—**Sowing Dactylis and Violets.**—If Dactylis glomerata elegantissima and Viola Admiration be shown now, should the plants be large enough for bedding out in May or June next? [Yes, if they receive liberal treatment.]

1692.—**Growing Caladiums.**—I have a few bulbs of Caladiums. When and how am I to plant them, in what soil, and what treatment do they require hereafter?—T. SPART. [Pot them in a mixture of peat and leaf-mould, with a little silver sand added, or light loam will do instead of peat. Put them in a temperature of 60° or 65°, and do not water too freely until growth commences. Put into larger pots as desirable.]

1693.—**Sowing Sweet Williams.**—These may be sown this month out in the common garden soil.

1694.—**Sowing Lobelias.**—Sow in a pan at once; put it in a frame or small house with a little heat. Prick out in small pots when large enough.

1695.—**Growing Potatoes.**—I have a garden in a sloping position which has the sun on it all the morning. It is about 60 ft. long by 18 ft. wide, soil of a brown colour, about 2 ft. deep, after which comes sand. I am desirous of growing Potatoes, but as I have had no experience I want assistance. If I make drills do I put the sets in the crevices or on the top? how deep? the eyes to be put up or down? what quantity of seed should it take? what sort? and when to plant them so as to have them early?—NOVICE. [Well dig the ground, then draw drills about 6 in. deep, and 2½ ft. apart. Then procure some early Ashleaf Potatoes, and plant them 2 ft. apart, eyes upward, of course. Cover them over, and leave the ground smooth. If the soil is very poor, a little thoroughly decayed manure might be worked in the drills with a fork with advantage, or a little artificial manure might be employed.]

1696.—**Sawdust as Manure.**—What is the value of sawdust as a manure? Will it benefit heavy sand?—F. X. [Yes; if it has been under horses and is decomposed.]

1697.—**Sweet Rhubarb.**—Which is the best and sweetest kinds of Rhubarb? Mine are very acid.—ANDERSTON. [Myatt's Victoria and Prince of Wales are both excellent kinds, the seeds or roots of which may be had from any good nursery.]

1698.—**Best Parsnips.**—*Anderston.*—The Hollow-crowned is an excellent Parsnip where the ground is not deep, and the Student is good for deep soils.

1699.—**The Alum Plant.**—Will some reader kindly give me the proper botanical name of the plant commonly called the Alum plant? the proper soil for it, how propagated, and the general treatment it should receive, especially in winter? Do the plants require watering often, and what heat?—LEARNER. [What is called the Alum root is Heuchera americana, a hardy plant, which grows best in peat soil.]

1700.—**Book on Gardening.**—*Apis.*—Get Hobday's "Cottage Gardening," post free from our office, 1s. 9d.

1701.—**Growing Lettuces.**—Could any one give me a few hints on growing White Cos Lettuces? I have a small handlight, 16 in. square; would it do to sow them in?—YANKEE. [Sow at once under the handlight. When up prick out the plants into a bed, finally planting them out in rich ground, where they are to remain. Later on it will be best to sow where the plants are to remain, thinning them out to the proper distance apart.]

1702.—**Treatment of Hardy Ferns.**—What is the treatment required to keep Daryopteria palmata and Asplenium bulbiferum in good health?—J. W. G. [A compost of sandy loam, leaf-mould, and old mortar rubbish; plenty of water, light, air, and shade.]

1703.—**Old Seed of French Beans.**—I have some Canadian Wonder Dwarf French Beans bought last year, but not sown. Will they do for this year?—F. X. [Yes; perfectly.]

1704.—**Soil for Fuchsias.**—Is it advisable to mix a fair quantity of peat with the soil for repotting Fuchsias? or what is the best soil for this purpose?—W. F. B. [If the soil is heavy a little peat would improve it. The best soil for Fuchsias is turfy-loam, leaf-mould, or decayed cow-manure and silver sand.]

1705.—**Transplanting Czar Violets and Carnations.**—Can these be transplanted now?—VERITAS. [Yes.]

1706.—**Transplanting Seakale.**—I have some Seakale just coming in; will the roots bear transplanting, as I want to move them away? What treatment should they have?—G. P. [Cut the Seakale first, then plant the fleshy roots where you want any future Seakale bed.]

Heating Greenhouse.—*W. H. C.*—We have given columns of information on this subject lately in GARDENING.

Gas Heating.—*J. M. C.*—We cannot recommend tradesmen.

An Amateur's Troubles.—*Herbert.*—See page 508, October 18, and p. 530, November 1, of GARDENING ILLUSTRATED.

Names of Plants.—*Isle of Man.*—Rhodanthe maculata and R. Manglesi (everlasting flowers). Sow in pots or boxes at once under glass. Put five or six plants in a 5-in. pot when large enough, and they will flower in summer.——*G. M. R.*—The winter Heliotrope (Tussilago fragrans); Moss; Selaginella denticulata.——*A. L.*—Santolina incana, sometimes called French Lavender.

QUERIES.

To Querists.—*It would help us greatly now that the number of queries asked each week is so great if correspondents would write all their questions on separate pieces of paper. We get many letters with five or six queries all mixed up on one small sheet of paper. This gives us much unnecessary trouble, and in some cases is likely to be a waste of time and paper to the writer.*

1707.—**Phalænopsis in a Stove.**—I have a stove of mixed plants which is kept at 60° in winter and 70° to 80° in summer; would the Phalænopsis amabilis and P. Schilleriana do well in it? They are expensive to buy, and if they would not grow there I will not try.—J. J.

1708.—**Making a Lawn.**—I am about to make a lawn, and have any quantity of moderately good turf close at hand, only rather foul with Daisy roots, &c. Would "J. P." explain exactly what he means by "pull it to pieces and lay it down bit by bit?" and does he think on a sandy soil near the sea I should do better with his plan than sowing with best lawn Grass seeds?—HOYLAKE.

1709.—**Growing Mushrooms.**—I have a corner in my garden 8 ft. by 3 ft., covered in on three sides and the top, in which I have tried to grow Mushrooms for the last two years unsuccessfully, either from want of sufficient heat or bad spawn. I shall be glad to know how I can hope to succeed.—HORTUS.

1710.—**Worms on Lawns.**—Can any reader tell me what quantity of water, hot or cold, is proper to mix with say ½ oz. of corrosive sublimate to destroy the worms on a grass-plat?—H.

1711.—**Pruning the Arbutus.**—Some of our Arbutus shrubs are bare and straggling, with large stems, and foliage only at the top; would it be safe to cut them right down to the ground to produce a good bush? Or what other treatment should they receive, and when should the operation be performed? The shrubs are near 20 years old.—W. CLIFFORD.

1712.—**Artificial Manure.**—Can any of your readers recommend from experience a good artificial manure for the garden? I have found much difficulty in obtaining rotten horse-manure and want something to fill its place. My soil is partly clay and somewhat stiff.—E. M. H.

1713.—**Cyclamens, Cinerarias, and Primulas from Seed.**—I want to raise some of these plants from seed. Will some friend give me instructions how to rear them?—A. H. J.

1714.—**Worms in Fern Cases.**—My Fern case is greatly infested by worms. Would soot or lime water kill the Ferns, which are just beginning to grow? There is a Maiden-hair in the case.—W GROCOTT.

1715.—**How to Make a Garden Pay.**—I have an acre of garden ground which has been used for a market garden, and which I want to turn to the most profitable use possible. There is no glass, and the ground is poor, with a chalky subsoil. I have carefully read "Multum in Parvo Gardening," or how to make £620 annual profit from one acre, but the reasoning is bad, and the facts no better. If the author would say where he got his bricks at 30s. per 1000 to stand the weather, and his bricklayer at 4s. and a boy labourer who could do the work at 1s. per day, we might be able to realise the happy fact of the cheapness of the walls; but any unfortunate amateur who is led away to make the trial will to his sorrow find the walls cost about double. "Our Farm of Four Acres" is, I find, about the same; the books are written to sell. What we want in books are dates and places given where the several things are obtainable at the prices stated in them, and the markets where they may be sold; so that we can verify the facts, and compare with our own counties. We can then see if it will pay to incur the first outlay of hard-earned savings, and so realise what to many enthusiasts would be like a retiring pension. Can any of the readers of GARDENING give me their experience in this direction?—WANDERER.

1716.—**Packing Trees for a Voyage.**—As I have the intention of emigrating in the course of a year or two, can any reader inform me whether it would be possible to pack fruit trees, such as Apples, Plums, and Pears, also a Vine or two, and a few favourite dwarf Rose trees, so that they would stand a voyage of about four months' duration, say, to the Island of Vancouver, on the north-west coast of America? Also what would be the most favourable time to start so as to ensure the trees growing on their arrival?—EMIGRANT.

1717.—**Rhododendron Leaves Going Brown.**—I planted several Rhododendrons last October, and they seemed to be all right till the frost appeared, when most of the top leaves went brown. Should they be cut back, or can I do anything to them to make them look more agreeable?—T. W.

1718.—**Nitrate for Plants.**—A friend having given me some of this, will some one inform me if it will be beneficial to Roses, and in the flower garden generally? Also what quantity to be used?—NICOLI.

1719.—**New Zealand Flax** (Phormium tenax).—How is this raised from seed?—C. P.

1720.—**Growing the Potato Onion.**—When must I plant, and what treatment must I give to this Onion?—W. D.

1721.—**Culture of Lilium longiflorum.**—I have tried to grow this in pots; I have also planted some bulbs in the open ground, but I cannot get it to succeed with me. Does it require any particular treatment? L. lancifolium and L. auratum do well with me in pots.—M. M.

1722.—**Plants for Unheated Greenhouse.**—I have an unheated lean-to greenhouse, 9 ft. by 7 ft., facing east. What would be the best plants to stock it with? The stage for the plants is waterproof, 4 ft. in front and 4 ft. 6 in. at the back of the floor. What would be the best use I could put the space to underneath? There is plenty of light under. Would a Mushroom bed do? or would it do to keep fowls under?—T. W.

1723.—**Sowing Malope grandiflora.**—What time is best to sow seed of this plant; and what soil do the plants thrive in best, and do they require heat? or will they grow quick in a frame without any? Also as to planting out, appearance when grown, colour, &c.—J. R.

1724.—**Smooth *versus* Prickly Cucumbers.**—I should like to be informed which of these would be the best, *i.e.*, most profitable, to grow in frames without heat during the summer. Would Telegraph give a larger and better crop than the Duke of Edinburgh?—W. B.

1725.—**Blood for Vines.**—I have been told that blood from the slaughter-houses is an excellent manure for Vines. I have been afraid to try it, being ignorant as to the time of year it should be applied, and how.—W. B.

1726.—**Cucumbers in Frames.**—Would some one give me a few hints relative to the management of Cucumbers in a frame? I have the frame and bed ready for planting. What are the best plants to grow?—FRAMEWORK.

1727.—**Cats in Gardens.**—What is a cheap method for making strong bird-lime? or could any one suggest something better to keep cats out of a garden which is walled all round?—ANTI-CAT.

1728.—**Forcing Tulips.**—Will any reader tell me the best mode of forcing Tulip (Duc Van Thol)? I have treated some in every way like Hyacinths. The leaf-spike has run up to the height of 4 in. or 5 in., but there is no sign of flower.—O. T.

1729.—**Cucumbers in Pits.**—I have just built a pit for Cucumbers. Will some reader tell me when I should have it heated with manure, and give me some instructions as to management?—P. L. R.

1730.—**Pruning Roses.**—When and how should such Roses as Baroness Rothschild, Duke of Edinburgh, Annie Wood, &c., be pruned to get them to produce flowers at the end of August for a flower show?—VERITAS.

1731.—**Sweet-scented Plants for Greenhouse.**—Can any one tell me the names of some sweet-scented plants suitable for an amateur's unheated greenhouse? The house is in a sunny position, and opening into a dwelling-room.—A. V. F.

1732.—**Plants for a Shady Landing.**—What plants or flowers would do well on a large, light, airy landing, the window facing north-east? Also what creeper would thrive best there? The sun only shines on the window for an hour in the day in the height of summer.—WOKINGHAM.

1733.—**American Blackberries.**—I have a few plants of the Parsley-leaved Bramble; how should I grow them?—W. B.

1734.—**Effects of the Weather.**—I very much want to know how to treat some Aucubas that have been terribly affected by the frost—in fact, I have to cut them down to about 1 ft. from the ground to get to any sound wood at all; and such is the condition of them all over Notts, and perhaps most of the Midland Counties. Are Deodars ever killed by frost? I have a magnificent specimen that looks as if all the life was gone out of it, with the exception of some branches at the bottom. Can anything be done to help it towards restoration? There is a layer of dead matter, 3 in. thick, all round the trunk, and more is constantly falling. Should this be left?—J. J.

1735.—**Plants for Bees.**—Would quantities of Mignonette planted near a beehive be advisable? I ask this as I have seen it stated that bees never gather honey near their own hives.—W. B.

1736.—**Potatoes for Exhibition.**—I have a garden the soil of which is very heavy. At the annual exhibition of vegetables near here a neighbour of mine invariably wins the prize for Potatoes by putting in the drills with the sets some mixture of the nature of which he refuses to inform me. Can any reader kindly tell me what I can cover the sets with to grow fine clear Potatoes?—AN AMATEUR.

1737.—**Starting Bee Keeping.**—I have been offered a stock or swarm of bees in the spring; would any reader of GARDENING kindly tell me when I ought to have them in? I want to get as much honey as I can the first year. I should like a few directions as to the best kinds of hives, the aspect for them, whether the bees would require feeding, how they should be packed to come 100 miles by rail, the implements, &c., I should require, and any information of interest to a novice in bee keeping; also the probable amount of honey a fairly strong stock, in an average year, should produce. Would it be cheaper to take all the honey, and feed them with sugar and beer in the winter?—W. B.

1738.—**Annuals and Biennials, &c.**—I should like a list of easily-grown and good annuals arranged in two classes, viz., those that admit or are the better for being transplanted, and those that do not bear transplanting; likewise a list of perennials and biennials which could be got to flower this year if sown in March.—EILDON.

1739.—**Sawdust as Manure.**—In GARDENING, Jan 17, 1880, sawdust manure is referred to as being useful for the cultivation of Celery and other garden purposes; will the writer say the method of using it for Celery, as this manure can be got as easily in London as in Manchester? Sawdust is used for the bedding of horses very largely by the London Omnibus Company and other large firms, and the material can be had in quantity by any market gardener or other person desirous of giving it a trial in London.—ONE PREPOSSESSED IN ITS FAVOUR.

1740.—**Treatment of Dracænas.**—How should one of these be treated which has looked very well all the winter in a sitting-room window, but now seems to be going off? It is a broad green-leaved kind, and is in a pot of 6 in. in diameter.—GLADIOLUS.

1741.—**Last Year's Seeds.**—I have a quantity of seeds purchased last season from one of the best seed growers. Will these seeds, if sown during the present season, germinate and grow this year as well as new seed? They are as follows: Lobelia erinus speciosa, Convolvulus major, Portulacca, Pyrethrum aureum, Sweet Pea, Tropæolum Lobbianum, Nasturtium, Ten-week Stocks, Lupinus, aloo-coccineus, Godetia Lady Albemarle, Candytuft, Tropæolum canariense, Virginian Stocks, Parsley, Lettuce, Turnip, and Vegetable Marrow.—FLORA.

1742.—**Fern Cases.**—Does any one know of a good plant suitable for hanging in a small Fern case? Also one or two suitable for climbing round a Fern case, fine-foliaged or otherwise?—ANON.

1743.—**Culture of Kalosanthes.**—Will some one kindly tell me the proper treatment for the above-mentioned flower? I have some last year's cuttings. Former attempts to make them blossom have failed.—F. A. S.

1744.—**Manuring Crops.**—Is a mixture of stable manure and Peruvian guano suitable for placing at roots of Gooseberry and Currant bushes, and would it also be suitable for Potatoes and other root crops? and in what proportions should it be mixed? Is salt a suitable manure to spread on the land, to be dug in and afterwards the above-named manure applied when dug a second time for Cabbages, Peas, Beans, Broccoli, Radishes, &c?—BONES.

1745.—**Cucumber Growing in Warm Greenhouses.**—Will some one kindly give plain and simple directions as to soil, pruning, and the application of manure water to Cucumbers in a warm greenhouse? Also, is sheep's manure good for them? and at what temperature should the house be kept?—W. H. R.

1746.—**Books on Flowers and Forced Fruit.**—I intend entering Covent Garden trade; can any reader give me titles of useful works on fruit and floriculture under glass likely to benefit me, with author's name if possible?—KEIVE. [There is a book on London market gardens just being published at our office which will be of advantage to you.]

1747.—**Shrubs for Various Positions.**—In planting a new garden the great difficulty one finds is the proper positions to set the trees in; to an amateur the high-sounding names fill him with fear and distrust lest the wrong sort should be bought. I have been greatly assisted by the advice given in GARDENING, but am entirely in the dark as to the positions the shrubs should be set in so as to have the tallest behind. Can any one assist me?—WANDERER.

1748.—**Soil for Potting.**—The soil in my garden is a heavy loam, and will not break up. When squeezed in

the hand it oozes through between the fingers. I read that in such cases the addition of sand would render it suitable for flowers in pots; accordingly I dried some of the soil and pounded it up finely, mixing a large quantity of sand with it. Upon drying when in the pots I found it got as hard as mortar, and required as much pounding to get it to pieces as before the addition of the sand. Will any one tell me what to do with it?—J. W. G.

1749.—**How to Make a Herb Bed.**—What aspect should it have? the best time to make it? What are the most useful herbs for a large household? Is it better to put in plants of each kind or to sow seed?—F. G. S. P., *Westbar*.

1750.—**Leather Dust in the Garden.**—Of what value is the above in the garden, and what plants may it be applied to? It is leather which in the finishing of boots by machinery is reduced to dust. I have also a quantity of ashes of leather. Having used waste leather for fuel this winter, I have saved it; there is no coal in it, but a good deal of wood has been burned with the leather. It is very light and powdery. Would this be useful also?—H. N.

1751.—**Mice in Garden.**—All seeds and bulbs in my garden are eaten by mice; and, although I use guards and have soaked Peas in diluted paraffin, nothing stops their depredations. What can I do to prevent such wholesale destruction?—H. A. S.

1752.—**Clematises for Bedding.**—Will someone describe the method of planting Clematises in a round bed? Are the plants to be placed alternate round the outer circle? What are the names of the best kinds for mixture of colour? What distance should there be between each plant? and could Clematises be safely planted at this season?—M. L., *Dublin*.

1753.—**Climbers for Walls.**—I have a Magnolia planted eighteen years ago, very vigorous-looking, and about 16 ft. high. It has never blossomed. I think of taking it out, and should be glad to know of some pretty compact-growing climber to put in its place. East aspect; about 20 ft. in height of wall surface. I have already round different parts of the house Yellow Banksian Rose, Wistaria, Pyrus japonica, Ivy (three sorts), Maréchal Niel Rose, White Jasmine, evergreen Honeysuckle, Monthly Rose, Virginian Creeper. I have had two Virginian Creepers die, but cannot discover the cause. A neighbour has also lost one; they gradually wither downwards.—M. L. B.

NOTICE.—The frontispiece of "Gardening" for Vol. I, a coloured plate of Rose Marechal Niel and La France, is now ready, and may be had through all newsagents and at the bookstalls, price 3d. with complete index. Readers should request that it be delivered flat and unfolded, to avoid injury to the plate.

Weekly, 1d.; Monthly Parts, 6d.,

GARDENING ILLUSTRATED.

PROCURING THE PAPER.—The best way, in all cases where it is possible, is to obtain it through the Newsagents, Booksellers, or Railway Bookstalls. Where, however, in country districts the paper may not be obtained with regularity, it can be procured by post from the Office. All the back numbers of GARDENING are in print, and may be had through the Newsagents or direct from the Office.

SUBSCRIPTIONS BY POST.—According to the postal tariff, GARDENING can be sent through the post to any place in the United Kingdom at the following rates:—Per year, 6s. 6d.; per half-year, 3s. 3d. No subscriptions received for a less period than six months. All payments for subscriptions must be made in advance. Stamps not received for subscriptions.

Post-Office Orders should be filled up in the name of THOMAS SPANSWICK, 37, Southampton Street, Strand, London, and made payable at the King Street, Covent Garden, Money Order Office. All Letters concerning Subscriptions to be addressed to—"The Publisher, GARDENING ILLUSTRATED, 37, Southampton Street, Strand, London, W.C."

For those who can only procure the paper regularly through the post a Subscription Form is subjoined.

Please to send me GARDENING ILLUSTRATED

for One Year, commencing _____

for which I enclose _____ *6s. 6d*

Name _____

Address _____

ADVERTISEMENTS.—SCALE OF CHARGES.—Five lines or less in body type, 3s.; each additional line, 6d. If displayed, or with blocks, &c., at the rate of 7½d. per line of body type, no matter what space they may occupy or what other type may be used. Set across columns, the lowest charge will be 30s. Advertisements for the next No. should reach the office not later than first post on Monday. Gardeners and others wanting situations, four lines, 1s. 6d.; each additional line, 6d.

ANSWERS TO QUERIES.—We earnestly invite all those practically capable to aid their fellow readers by giving such information as may lie in their power. All answers should be written on one side of the paper, and commence with the number and title of the query.

All communications for the Editorial Department should be addressed to THE EDITOR, GARDENING ILLUSTRATED, 37, Southampton St., Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same address.

The name and address of the writer are required with every communication, though not for publication, unless desired by the writer. Letters or enquiries from anonymous correspondents will not be inserted.

Post Office Regulation.—Inconvenience and loss is experienced by advertisers overlooking the rule of the Post Office, which forbids postmasters to receive letters addressed by initials or fictitious names only. Therefore answers to advertisements sent cannot reach the advertiser.

To our Readers.—The aim of GARDENING being the dissemination of the very best practical information through every class of the community, the Editor would be greatly obliged to all who receive it if they will make it known to any persen interested in the subject.

NOW READY.—CASES for BINDING Vol. I. of GARDENING ILLUSTRATED. Price 1s. 6d. To be obtained of all booksellers, newsagents, and at the railway bookstalls, or from the publishing office, 37, Southampton Street, Covent Garden, London, W.C. N.B.—The binding case cannot be sent per post.

"Gardening" Volumes.

THE First Volume of GARDENING will be published early next week, and will contain the whole of the numbers issued since its commencement to the end of February. Also a complete Index, Title-page, and a beautiful Coloured Frontispiece showing the two finest Roses raised in our time. It will be well bound in green cloth, gold lettered, and be a valuable book of reference. May be obtained through all Newsagents and Bookstalls in the United Kingdom, price 7s. 6d.

Back Numbers of "Gardening Illustrated."

READERS who may have incomplete sets of this Journal are requested to complete them as soon as possible, as all the numbers are now obtainable.

THE SUB-TROPICAL GARDEN has beautifully-engraved figures of all the important types of hardy plants useful in obtaining picturesque effects in the garden. Price 5s.—GARDEN Office, 37, Southampton Street; and through all booksellers.

ALPINE FLOWERS for ENGLISH GARDENS.—With numerous fine illustrations. Price 7s. 6d.—London: JOHN MURRAY, Albemarle Street, W.; THE GARDEN Office, 37, Southampton Street, Covent Garden, W.C., and through all booksellers.

GARDENING ILLUSTRATED.

VOL. II.—No. 54. *SATURDAY, MARCH* 20, 1880. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

DAFFODILS.

THESE, the hardiest and showiest of spring flowers, are now making a display in garden, field, and meadow; and, though often looked upon as common flowers, there are no plants more worthy of being well planted and cared for in our gardens than the various species of Daffodils, of which there are now a host of most beautiful varieties. They vary so much in size, colour, and form, that a most attractive garden may easily be made with Daffodils alone. Many of the Daffodils are used extensively for culture in pots, and they may be seen in our markets in quantity as early as February. There are but few species or varieties of Daffodils that will not succeed under ordinary circumstances in the open border. A few kinds—principally from Algiers, Spain, and the islands in the Mediterranean—flower mostly during the autumn and winter, and consequently are not adapted for outdoor cultivation, except in very favourable situations. Fortunately, however, there are, as we have said, but few of this character; the great bulk are not only perfectly hardy, but will grow in almost any soil or situation, and increase in numbers rapidly. By means of hybridisation, too, it is possible to obtain varieties much superior to any yet in cultivation; and the process is so simple that any one may practise it with a fair chance of success. Indeed, by this method many very beautiful kinds have been raised within the last few years. Most of the Narcissi, as the Daffodils are called, prefer a good rich, friable loam, annually enriched by a top-dressing of manure; but care must be taken to keep the manure away from the bulbs while in a fresh state. The small early-flowering kinds should be planted in sandy loam, and in rather drier positions than the more vigorous forms. All this family require replanting every three or four years, some even in two; but this depends a great deal upon the conditions under which the bulbs are placed. The best criterion as to when they require replanting is the production of small, weak foliage and a scanty proportion of flowers. When that occurs one may make sure that the bulbs have exhausted the soil, and that they have not sufficient room and strength to fully develop themselves. When this lifting process takes place, before replanting, the whole of the soil should be well dressed with old manure and be thoroughly dug or trenched: if the latter, let the ground be moderately well trodden over to firm it, as the roots of all plants—and more especially of our Daffodils—like to fight their way against a pretty solid resistence; and remember that the popular notion of lightness in the texture of the soil being beneficial to root development does not always prove true. Rarely do we find the roots of the Narcissi inclined to branch; and as a result, when the growing point becomes injured the root really ceases to be of any value towards the sustentation of the plant, as decay sets in and the entire root soon disappears. When, therefore, in removal more than one-half of these delicate feeding processes are virtually destroyed—which is sure to be the case if they are developed to the length of half an inch—it will not be at all surprising that the plants receive such a severe shock as to cause blind and imperfect flowers. These may also originate from another source. The beautiful old-fashioned double Pheasant's-eye Narcissus, a favourite with every one, alike for its purity and its perfume, is one especially liable to this when it has been grown for many years in the same locality. This arises from sheer exhaustion of the soil, and may easily be guarded against by a winter's dressing of nice short rich manure, or by a few copious waterings with diluted liquid manure during the spring growth. The former is preferable, as it answers in the double capa-

GROUP OF CYCLAMEN-FLOWERED DAFFODILS (NARCISSI).

city of protector and stimulant. The roots of all these plants are in a vigorously active state during the entire winter. Hence it is advisable that they should have their stimulating dose early, and that it should be gentle and constant. There is no place where the Daffodil does better or looks more lovely than when springing from the Grass: there, if he nods his head beneath the weight of the accumulated moisture of a succession of spring showers, no taint of Mother Earth tarnishes his purity—nay, rather, he rises again with returning sunshine, fresher and brighter for his bath. On trim-kept lawns, where the very first growth of the green sward calls into existence the noisy rattle of the mowing machine, groups of Narcissi are not by any means happy; but let us ramble beyond the precincts of culture and cast a glance at a group in the open field, or adjacent to some shrubbery where the scythe but once a year steps in to Nature's assistance, and what do we find? The leaves rise green to the tip, from a mass of mingled Moss and Grass, interspersed with the bright brown foliage of the Beech or the paler Oak, whose various tints lend a contrast to the fresh glaucous hue of the Daffodils. But, besides adding to the beauty and harmony of the picture, these adjuncts, combined, have fulfilled the purpose of admirably protecting the buds in their early growth, and now combine to support the slender leaves against the mutilating influence of the wind, and, further, in the decay of the withered Grass and leaves below are assisting to restore the elements of fertilisation to the soil.

The margins of shrubberies are amongst the best places in the garden for the Daffodil; there are always little indentations—natural irregularities arising from the difference in growth of adjacent shrubs—where the mowing-machine does not come; corners, we may say, still sacred to the scythe. In these, with admirable effect, may groups of Narcissi be placed, where respect can be paid to their leafage, so that it be not cut over before it naturally fades away. Do not obtrude them on the lawn in scattered patches, where they but mar the quite repose of the green sward. Whether it be a rootery or a rockery, or a combination of all together, our Narcissi will also be found quite at home. There will be presented all the elements of successful culture, and there they will find happy associates in the wood Forget-me-nots, the variegated Dead Nettle, the Wall Cresses, the Aubrietias, and a host of similar plants, not to mention the bright Moss-covered nooks and crannies rich in the verdant colour of their delicate tracery. Here then may a collection of Narcissi be maintained in a natural condition, each sort grouped by itself, with an unobtrusive number, by which, on reference to your note-book, the name and history of each variety may be obtained.

The woodcut on our front page represents some of what are called Cyclamen-flowered Narcissi, and, though too delicate to be planted generally, they are well worth culture in warm sheltered districts; and they also make excellent plants when grown in pots for the greenhouse. The names of those represented are N. calathinus pulchellus, the creamy white N. calathinus, and N. triandus. Daffodils are now largely cultivated in nurseries, among which we may mention those of Messrs. Dickson & Sons, of Chester; the Lawson Nursery Company, Edinburgh; Mr. Smith, Newry; Messrs. Backhouse & Sons, York; Messrs. Barr & Sugden, Covent Garden; Mr. Ware, Tottenham; and Mr. Parker, Tooting; and as this is the time the Daffodils are at their best, those wishing to make a selection could not do better than visit the nearest nursery to them, and choose for themselves; or any nurseryman who makes them a speciality will send a varied and good collection for any stated purpose at a cheap rate on application.

The Dog's-tooth Violet (Erythronium Dens canis).—The flowers of this droop somewhat like the Cyclamen; and, though a very small plant, it has a flower of a lovely rosy-lilac, so large as to remind one of those tropical climbers more than of a true Alpine flower, which it is. The foliage, also, is singularly unlike any other Alpine flower, being deeply spotted with brown, so as to resemble some of the fine-foliaged plants popular in our stoves. This flower is the Dog's-tooth Violet, long known as an inhabitant of our gardens, but which, with many other flowers, has been for some years so neglected, that it was only in a botanic garden, or curious collection here and there, that one ever caught a glimpse of it. There is no flower known more worthy of a place in our gardens. It has several beautiful relations, mostly natives of America, but as yet scarce in our gardens. They will probably not be long so, as the fine E. grandiflora is abundant in the Rocky Mountain and Utah region; while the yellow Dog's-tooth Violet is as common among the wild herbage in many parts of the Eastern States as the Daisy is in our lawns. In our gardens the Dog's-tooth Violets thrive best in warm sandy soils; indeed, the beautiful European kind, the finest of all, is only seen in perfection in warm soils. It will grow in any kind of soil, but on cold clays one must frequently be content with the beauty of the leaf only, as the blossoms are not formed. Where clay soil occurs naturally, it is best to grow the plant in prepared soil, in a raised position, in the lower parts of the rock garden or hardy Fernery. Where sandy peat or free loam admits of its thriving perfectly, the Dog's-tooth Violet should be abundantly grown among the

Dog's-tooth Violet (Erythronium Dens canis).

bulbous flowers that bloom in early spring, and it will look well either in clumps or small beds, or as a carpet beneath choice American shrubs in peat soil. The leaves die down more rapidly than those of most bulbs, and care should be taken that it is not injured by accidental disturbance. As a carpeting plant to small beds of choice growing shrubs, it would probably be as little liable to accidental destruction as in any other position. The roots of this plant suffer from being kept dry; and therefore they should, when taken up for any purpose, and not replanted soon, be stored in Cocoa-fibre or wet sand. We have never seen this plant in such good condition as in Messrs. Barr & Sugden's trial ground at Tooting, where large beds of it are studded over with its showy blooms. Mr. Barr cultivates the following varieties:—E. Dens canis album, majus (red-purple), majus roseum (rose-purple), majus album (white, bottom of flower brown), and passiflora (light purple, shading to blue).

Daisies in Towns.—In densely inhabited districts where other spring flowers do not flourish these will grow and yield a continuous round of blossoms for a lengthened period. As regards colour they combine every shade from the purest white to the deepest crimson; they are plain and quilled, and often singular as regards growth, as, for instance, Hen and Chicken Daisies. Hyacinths and Tulips are beautiful, but short-lived, a remark which also applies to many other spring flowers. Aubrietias, Arabis, Pansies, and many others often damp off under the dull smoky atmosphere of London; therefore when we possess such a staunch friend as the Daisy we should make as much use of it as we can. During ordinary winters Daisies are

Double Daisy.

seldom without flowers, and they will continue to bloom until removed to make room for summer bedding plants. A packet of seed costing a mere trifle will produce hundreds of plants. The seed should be sown in shallow boxes in light sandy soil any time during June, and the boxes should be placed in cool shady frames after a good soaking of water has been given them. The young plants soon make their appearance, and when sufficiently large to be handled they should be pricked out in the open ground 2 in. apart, giving them at the same time a thorough watering. Daisies love water, and are very tenacious of life. They rarely die even if thrown on the surface of the soil, provided there is an abundance of moisture. They grow rapidly and soon become a solid mass, when they can be taken up like turf. They should then be divided and planted in the beds where it is desired they should bloom from 4 in. to 6 in. apart. In February they commence to grow, and by the first week in March they are in full flower; and, as already mentioned, continue so incessantly until removed in May to make room for bedding plants. It will thus be seen that our beds might be carpeted with flowers at a season when blossoms are extremely scarce, and that at little trouble or expense.

Hardy Flowers for Profit (1589).—Those who lay themselves out to grow hardy flowers for sale should restrict themselves to a limited number of kinds, choosing only those which are always more or less in demand, and which are distinguished for their exceptional beauty. This remark especially applies to those who, living at a distance from thickly-populated places, would have to depend upon customers coming to or sending to them from a distance. There is, for instance, the Christmas Rose, which may be raised with ease from seed if sown as soon as ripe. This beautiful winter-flowering subject is always in demand, and fair remunerative prices may be obtained for it. Its variety Maximus should also be secured. Then there is the Pansy, of which, if a choice selection be secured, the young seedlings or cuttings may be

---

disposed of. The great point is to grow only the very best varieties, so that the seedlings may be recommended as of superior quality. Bedding Violets, too, are in great request, and are of easy propagation. Spiræa japonica and Lily of the Valley are favourite plants for forcing, and if grown liberally will increase rapidly. I would, however, advise as a speciality the culture of the many beautiful forms of Primrose. Those who can get a stock of them will find no difficulty in disposing of them. A large nurseryman lately informed me that he found it impossible to procure enough of the better kinds. The finest varieties being kept true to name and propagated by division, the seed may be saved, and a quantity of young plants raised which would find a ready sale. In the neighbourhood of a market town the bright-flowered, free-growing kinds of Polyanthus would be easily disposed of, as would also nice little tufts of Myosotis dissitiflora, Aubrietia purpurea, Daisies of kinds, Campanulas carpatica, turbinata, and garganica, Gentiana acaulis, &c. Anemone japonica and its white varieties should also be included in the list which may be disposed of in the trade. There are other good things besides those enumerated, but none better or more likely to command a sale.—J.

Neapolitan Violets to Bloom in Winter.—Divide the old plants after blooming in spring, and plant the runners on a cool border in rich light soil. Plant in lines a foot apart, and 10 in. from plant to plant in the row. Keep the surface stirred, and give copious waterings in dry weather. In September, take the plants up with good balls, and plant them in a frame near the glass in a sunny and sheltered situation. Give plenty of air when the weather is severe, and keep off the lights altogether in mild autumn weather.—O.

French Lavender (Santolina incana).—This is one of the most useful of plants for forming edgings or divisional lines, and, being of a whitish-grey tint, it may be employed in many varying combinations. Its habit of growth is neat and compact, and, being hardy, it especially commends itself to those who have but a limited amount of glass structures. I put some cuttings of it in under hand-glasses or lights in September which will make excellent little bushy plants for furnishing beds this spring. By having a good supply of this, and such plants as Violas, Polemonium cœruleum, Golden Thyme, and similar plants, bedding-out, as it is called, becomes a more reasonable affair than when all the subjects employed are tender.—J.

Sowing Sweet Peas.—Sowing these where they are to bloom is much to be preferred to sowing them in pots or boxes; and if I were asked to name a time at which to sow them, I should say the middle of March, if a good long season of bloom be wanted. Last year I sowed at the time just named in the open ground, and also a few in pots, for the sake of experiment, in soil well prepared. Those in pots I put under glass, and when up hardened them off in a cold box pit, afterwards planting them out beside the others. Those sown in the open ground commenced blooming as soon as those from pots, were much stronger, yielded much the largest quantity of bloom, and continued longer in that condition; in fact, they bloomed till the flowers were killed by frost. I find that if one wants them to bloom for a long time continuously, it is a good plan to cut off any pods that may form on them as soon as they are visible, as the pods if left on the plants exhaust them, and they soon cease blooming profusely.—C. F.

Spring Bulbs in Rose Beds.—For several seasons, after having flowered our bulbs in pots, we have planted them out in beds, and banks of Roses, and the two certainly appear to advantage together, as the bulbs give a bright cheerful appearance to beds which at this season would be nearly bare. As the Roses are pegged down, only the strongest young wood of the preceding year's growth is retained at pruning time, and the Roses may be set at tolerably wide distances apart, which allows ample space for a few clumps of Hyacinths Narcissi, or Tulips, while a good margin may be allowed for an edging of Crocuses, Snowdrops, or Squills. We annually top-dress but never dig the beds, and the bulbs are nearly ripened off before the shade from the Roses becomes dense enough to injuriously affect them.—J. H.

VEGETABLES.

HOW TO GROW ENDIVE.

Endive is not much grown in small gardens, but it is an excellent salad and quite as easy to grow as Lettuce during summer. In order to have Endive in its highest state of perfection liberal treatment is necessary, both as regards soil, manure, water, and timely attention to blanching. The first crop to be grown in the open air should not be sown earlier than the end of May, as early-sown plants run to seed; other sowings may be made at intervals of a fortnight up to the end of August. The seeds should at all times be sown on fine, rich, moist soil, and they may be either put in broadcast or in drills. Many adopt the latter method, and thin out the plants to the required distances apart, instead of transplanting them, as is generally done; and in the case of early crops a decided advantage is thereby gained, inasmuch as thus treated the plants are not so liable to run to seed as when subjected to transplantation. In any case the soil containing the plants should be kept in a moist state by means of frequent waterings through a fine rose if the weather be dry; weeds should be promptly eradicated as soon as they appear. Thin out the plants as they advance in growth until they are 3 in. or 4 in. apart, after which they should be allowed to remain until several leaves are made, when they may be carefully lifted from the seed-bed and transplanted where they are intended to remain. Early and late crops do not require so much room as those

The Batavian or Lettuce-leaved Endive.

that are fit for use in the middle of summer, but the average distance will be found to be about from 12 in. to 15 in. each way from plant to plant. It must, however, be remembered that the Batavian Endive always requires more room than the curled-leaved varieties. Previous to planting the ground should be deeply dug, and well enriched with good rotten manure. In very dry seasons copious waterings will be necessary, in order to keep the leaves in a quick-growing and consequently crisp and brittle state, which latter is most essential to flavour and general excellence. Weak manure-water occasionally applied to the roots, without wetting the foliage, will be found to greatly assist their growth.

Blanching is generally done two or three weeks previous to the heads being required for use, but if, as should be the case, the plants be allowed to attain nearly their full size before blanching takes place, eight or ten weeks must elapse from the time of sowing before blanching is attempted. Many ways and means of blanching are resorted to, the most common being that of laying the leaves together in the same way as in that of Lettuces; if tied in two places instead of one, as is often the case, *i.e.*, one in the middle and one at the top, the blanching will be more complete than it otherwise would be. Some invert flower-pots or Seakale pans over the plants, which is, perhaps, the least troublesome method of any. Others cover the heads entirely with dry soil. Straw hurdles, too, put over the plants in such a manner as to exclude light from them, is a very easy and effectual way of blanching; and by continually moving these onward, as the heads are cut, a successional supply of well-blanched Endive may be secured. No more than is likely to be used should be blanched at a time, inasmuch as after a certain period flavour and crispness gradually decline. Flat tiles or slates are also sometimes used for blanching, first pressing down the hearts of the plants with the hand, and then applying the tile or slate, afterwards covering the whole with earth or dry straw. Whatever process of blanching may be preferred, it should at all times be done when the foliage is dry, otherwise discoloured or rotten hearts will be the result. Taking all things into consideration, there is perhaps nothing better for blanching Endive than the common flower-pot, or seed-pans without holes in the bottom.

There are two distinct types of Endive—one with narrow curled leaves, the other with broad leaves like those of a Lettuce. The curled-leaved varieties are the handsomest looking, and are more easily blanched than the broad-leaved kind. The leaves of the latter are, however, more crisp and better flavoured than those of the former. Amongst the best of the curled-leaved kinds may be mentioned Digswell Prize, Gloria Mundi, large Green-curled, and French small Green-curled. The last-named is only fit for early and late sowings. The best of the Batavian kinds are green Batavian, Round-leaved Batavian, and the white Lettuce-leaved Batavian.

Sprouting Potato Sets.—Though this is a common enough practice, it is not so frequently observed as it ought to be. Sprouting the sets is of the greatest importance in unfavourable seasons, when planting cannot be proceeded with, and also in late and cold situations. Sets sprouted about this season and planted out in April or even in May, will produce a crop weeks before those planted without sprouting, though the eyes may be moving. Sprouting, however, requires to be done in an intelligent manner. It is a bad plan to start the tubers in strong heat, as in that case the shoots come weakly, and after they are put out, even if hardened off previously they often go off by canker or damping. A cellar is as good a place as any in which to start seed Potatoes, if a little light can be admitted to it, as the temperature is usually high enough to cause the sprouts to move gently, and if the Potatoes be spread out thinly upon the floor the sprouts will not be weak and drawn.—S.

Dwarf Peas for Small Gardens.—Inquiries as to what are the best sorts of Peas for small gardens, kinds that want no sticks, are so often addressed to me that I have no doubt there are others beside my correspondents to whom the information would be welcome. Advancer is the best early dwarf Marrow. For a middle crop use Maclean's Wonderful, and for the latest, Laxton's Omega. These are the dwarfest of their class. Another good selection, rather taller, but still classed as Dwarf Peas, are Princess Royal, Premier, and Veitch's Perfection. All of these produce Peas of the very best quality.—A.

Onion Seed.—A Bedfordshire grower of seeds has land in this locality, and grows here a considerable crop of Onion seed annually. He plants the bulbs at this season, or earlier, in rows running from east to west, about 6 ft. apart, and utilises the intervening spaces for the growth of ridge Cucumbers or Gherkins, but the latter chiefly. The Onion bulbs are planted in the rows as close together as is consistent with good growth, and when the stalks are fully grown they form shelters both from hot sun and wind for the Cucumber plants. When the centre pods are ripe the heads of the Onion seed are cut and dried off in the sun, the stalks being allowed to stand until the Cucumber season is over.—Hounslow.

Vegetable Marrows on Refuse Heaps.—This useful vegetable may be grown in the greatest abundance on ground that could scarcely be utilised for any other crop. Our plan is to collect all refuse, such as sweepings of lawns, walks, &c., in pits during the year, and wheel it into one large heap during frosty weather in winter. The most decayed portion, "like leaf mould," is placed on the top, and a good covering of old potting soil is spread over the whole. On this heap plants of either the Long Green or Custard Marrow, raised in heat in March, and hardened off, are planted under hand-lights, which they quickly fill, when they are raised on bricks, and the shoots trained out regularly over the bed. The only attention which they require is watering during periods

of drought, thinning the foliage and shoots when crowded, and cutting all fruits as soon as they are large enough for use. Thus treated, they never fail to produce abundance of fruit until the early frost cuts them off. The whole heap is by this time in good condition for trenching into any stiff fresh broken land, which is greatly improved by additions of this sort of compost. —D.

Transplanting Onions.—If not already done, no time should be lost in getting a good breadth of autumn-sown Onions planted in good rich soil, 9 in. apart each way, for summer and autumn consumption. In lifting the plants care must be taken to get the roots up as perfect as possible by loosening the soil with a fork as deep as their extremities, and holes also should be made deep enough to drop them into full length. Thus treated, they will start at once into active growth. The most popular sorts for autumn sowing are the Giant Rocca and Globe and Flat Tripoli, but the mild flavour for which they are esteemed depends very much on their culture. —H.

Hints on Turnips.—On some soils, raising very early Turnips is a difficult matter, as, when the young plants have passed through the vicissitudes attending their early existence, unless carefully managed they may run to seed at the very time when they ought to be ready for use. Under these circumstances, unless the land be peculiarly well suited for Turnip growing, April will be early enough to make the first sowing. A sprinkling of superphosphate applied at the time when the seeds are sown will also make its presence known by pushing on the crop, and should never be omitted where the fly is troublesome. Sow in drills 1 in. deep, 1 ft. apart, and thin the plants out to 1 ft. asunder in the rows. During hot weather, for the successional sowings, the drills should be drawn a little deeper, and they should be thoroughly soaked with water before the seeds are sown. If the latter lie too long in the land, the plants always come patchy and weakly. As regards varieties, there is no better all-round Turnip, for either large or small gardens, than Red Globe, and especially for an unfavourable soil in a dry season. Silver Ball is a very handsome Turnip for early sowing, and the Chirk Castle Black Stone is very hardy, and may be sown towards the end of July or beginning of August for standing the winter. Where a succession is required, it is better to sow a small bed every three weeks than to sow a large one at long intervals. When the early Potatoes are lifted, Turnips may be sown immediately on the land so cleared without much preparation of the soil, beyond levelling it and giving it a sprinkling of some artificial manure.

French Beans.—These are fond of well-pulverised, sweet, rich soil. They should not be planted till the middle of April in the open garden (as on account of the damp, cold state of the soil they are liable to rot), and then only on warm, sheltered borders, or in places where they may be sheltered and protected from the cold wind and morning frost. My own plan to obtain an early, even, and prolific first crop out of doors, was to sow in a frame, or under a hand-glass, or in a box or pan placed indoors, or under shelter; harden off and transplant on a warm border or quarter, well prepared, in trenches or on the flat, with a ridge of earth cast up for shelter on each side, and protect them by night and in cold windy weather with light straw mats, evergreen boughs, Fern, Pea haulm, or any similar materials. This shelters and forwards the crop very considerably. The following have been proved to be good varieties:— Light Dun or Cream-coloured, Mohawk, Dark-speckled, Negro long-pod, Sion House, Osborne forcing, Newington Wonder, Dark Dun, Fulmer's, Robin's Egg, Early White, and Wilmot's Early forcing.—B.

Prizes for Vegetables.—Messrs. Webb & Sons, of Wordsley, Stourbridge, offer prizes for competition at the principal horticultural and agricultural shows to be held in 1880. At the Royal Horticultural Society's meeting at South Kensington on June 29, a prize is offered for a collection of six distinct kinds of vegetables; at the International Potato Show for specimens of Schoolmaster Potato; and at the Royal Oxfordshire Horticultural Society's Show at Oxford on July 21 for a collection of six distinct kinds of vegetables.

ROSES.

Work to be done to Roses now.—Roses in most gardens are now in so forward a state as to necessitate immediate pruning in order to have dormant eyes to prune back to. The present time is considered, I believe, by amateurs early for the operation; but, from considerable experience on a very large scale, I think pruning should be done earlier in the season than it is in general. The season will somewhat modify the pruning. One must prune back closer than ordinary to have a good unshot eye to start with. Thin the shoots well out, leaving no wood in the head that is not healthy and fairly vigorous. Study the individual habits of the Roses, the catalogue descriptions of vigorous, robust, and moderate being in some sense guides. For instance, Maréchal Vaillant, a vigorous kind, does not bloom if cut in close. Its shoots require to be left at least 1 ft. to 1 ft. 6 in. in length. Robust Roses, as Madame Vidot or Baroness Rothschild, with short stumpy wood, should be pruned to a prominent bold eye—the best on the shoot, high or low. The small wood of these sorts never yields blooms worth having, and must be cut clean out. Moderate Roses, as Mdlle. Bonnaire or Xavier Olibo, need close pruning. They may be cut in almost to the old wood—quite so when the shoots are weak. The eye to which the shoot is pruned should, if possible, look outwards. If this rule is followed, a hollow head will be formed, allowing air to

The Damask Rose.

circulate well amongst the foliage and flowers. Prune, if possible, after a day's drying weather, as if the ground is in good order Roses do not bleed badly. Choose likewise fine weather to dig the ground, turning in some manure, unless this has been already done, when a mulching of some short horse manure (road droppings, fermented by having been in a heap, are good for them) may be applied early in April. Make good all vacancies in borders where the kinds to be planted are Hybrid Perpetuals, Noisettes, and standards of the Teas, and reserve places for dwarfs of Tea Roses, which are better planted from pots in May. In the forcing houses a few kinds started in November will be just opening. Souvenir d'un Ami, Madame Falcot, and the white Hybrid Perpetual Marquise de Montemart, are amongst the first. Where plants are just breaking syringe twice a day, which will also supply almost sufficient moisture to the plants; 55° to 60° is a good day temperature, which may fall to about 50° at night. All pot Roses should now be pruned, as after May, grown under glass, they do not compare favourably with the early flowers from out of doors. It is well, therefore, to get all pot Roses over by the end of that month. Pot Roses should always be pruned some days before being started, however slowly, into growth.

Rose Insects.—There is one difficulty inseparable from the cultivation of Roses, and that is their liability to insects; the three principal with which the grower has to contend are aphides, the Rose maggot, and red spider. As these, like all other insects, are much more easily kept down when attacked as soon as their presence is detected, no time should be lost in washing the trees. A good syringing with Quassia water will kill them; but, for its effects in destroying both the mature insects and their eggs, and also in rendering the newly-expanded leaves distasteful to them, none of the many remedies prescribed are equal to Tobacco-water to which has been added 2 oz. or 5 oz. to the gallon of Gishurst compound. The influence of this is such as to correct the oily nature of Tobacco-water in a way that makes it stick to the affected buds and leaves much better. From the insect-destroying properties of the Gishurst itself, the Tobacco-water when used with it may be employed much weaker than when applied alone. A dry day should be chosen for the work, which will enable the wash to adhere to the leaves better. A timely application of this sort will be found of considerable use in preserving Roses from the maggot, rendering the young leaves which are first preyed upon distasteful to the grub. The advantages of syringing and dipping the shoots of Roses affected in this way over dusting them with any powder disagreeable to the insects, is that it reaches all parts much more effectually with less waste.

Banksian Roses.—Our Banksian Roses are always exceedingly floriferous, so much so as to be literally white with blossoms every year, unless they get cut off by frost. We prune them hard in as soon as the flowering is over, and then during the summer we cut out all the strong growth and thin that of medium size, so as to let in plenty of sun and air to thoroughly ripen it. The young shoots made under this treatment vary from 1 ft. to 1½ ft., and bloom at every bud, thus forming perfect wreaths of a length most serviceable for cutting. I ought to add that the plants referred to are on a south wall, where they cover a large space. Anyone having their plants in similarly favoured situations may, by managing them in the same manner, have any quantity of flowers; and the same holds good with such Roses as Maréchal Niel, Gloire de Dijon, Climbing Devoniensis, and most others of that class.—S.

Mulching Roses.—Covering the surface of Rose beds with rotten manure is of the greatest importance to secure a satisfactory crop of flowers during the current season, and equally necessary to the production of strong growth for the ensuing year's bloom. This is especially the case in dry situations, where the soil becomes parched during the summer season, and is much more effectual than the application of even an unlimited quantity of water alone, and is quite independent of the body of soil in which the plants are grown having been previously well enriched. The applying of manure in this way to standards, half-standards, and such as are grown bush fashion may be delayed some weeks; but with those that are grown on their own roots to be pegged down, the mulching should be put on directly the pruning is completed before the shoots are pegged in the positions they are to occupy, or it cannot be conveniently done afterwards. Previous to this, as soon as pruned, the beds should be forked over, pointing in at the same time any manure that may be needed to incorporate with the soil.

London Market Gardens.—Mr. Shaw's book on London Market Gardens will be ready next week and is published at our Office. He tells the facts respecting the culture of vegetables, flowers, fruits, and plants for the London market as they have not been told before. The author is familiar with the subject about which he writes, and is well acquainted with practical gardening. His book will, we feel, be sure to meet a want. The following article on the culture of Moss Roses will convey some idea of the kind of information the book contains:—

"In July, Moss Roses form a most attractive feature in our flower markets, large piles, baskets, and bunches being found at every turn. The white kind, though not common, is used for bouquets, and two or three red and pink sorts are supplied in enormous quantities; indeed, there is always a great demand for Moss Roses in our markets. The old Provence Roses, too, are, during summer very plentiful and in great

demand, and buds of the White Provence are very beautiful. The common Moss Rose, so well known in our cottage gardens, is not very largely cultivated by market gardeners, the reason being that it is neither robust nor floriferous enough for market purposes. The variety most preferred is a deep red kind, which, though less mossy than the common sort, produces blooms in much greater abundance, strong shoots bearing from eight to ten buds, all of which open well, at one time; but they are never allowed to be too much expanded before they are cut, as in that case the mossy portion would be less noticeable and the value thereby reduced. To supply the great demand for Moss Roses, many market gardeners round London devote several acres of land to their culture. They are, however, seldom all grown on one spot, but are distributed about in patches, some being in a warm border sheltered on the north by a wall, hedge, or row of fruit trees, others growing right under orchard trees, and the main crop is usually found in open quarters. This arrangement is admirable, inasmuch as it affords a lengthened season of cutting. The border plants furnish the earliest blooms. These are succeeded by those under the fruit trees; and the late blooms are furnished from plants unprotected. Moss Roses are cultivated much after the same fashion as the Raspberry, with this difference that the old wood of the Roses bears a crop two or three years in succession before it is cut away, whilst that of the Raspberry is cut away yearly. Well established plants are, however, so productive of young growths at their bases, that it is found necessary to keep the bushes well thinned of the old wood as well as of the weakest of the young shoots. Moss Roses in market gardens are grown on their own roots, and it is probable that no form of budding or grafting on any kind of stock would give the fine results obtained from these plants. They thrive well under orchard trees and form one of the most renumerative of under crops; for, with the shelter which the overhanging boughs afford them, frost does them but little damage, whilst those growing in open quarters often suffer severely from late spring frosts. The plan by which the plants are sometimes increased is to lift the old stools and strip off the outside shoots, which are freely produced, and plant them in rows 2 ft. apart each way in good soil. During the first two years after planting dwarf-growing vegetable crops are sometimes taken from between the rows, but after that time, if the Roses have done well, they require all the space. During winter, as already stated, a portion of the old wood and the weakest of the young growths are removed. Robust shoots, too, are shortened back, the soil is lightly forked over, and a good mulching of rotten manure applied. In this state the plants remain until the buds are ready for cutting, when they are gathered every alternate morning for market, the whole truss being removed at the same time with a few leaves attached. Some growers plant Moss Roses between bush fruit trees, but it is not a good practice, inasmuch as in a short time they form a complete thicket, much to the injury of both crops. Where no fruit bushes exist the rows are intercropped with Brussels Sprouts, Shallots, Broccoli, or some similar crop. The strongest shoots of Rose trees after blooming are sometimes layered on both sides of the row and firmly pegged down; and during the summer these layers, which will have rooted, are lifted, and after being trimmed are planted in rows, as before described. By this method healthy young plants are obtained without in any way destroying the existing plantations. Moss Roses and Pheasant's-eye Narcissus are sometimes grown in rows alternately. The Narcissi are generally over before the Roses are in leaf, and thus neither crop is in any way injured. In the middle of July at nearly every corner of the streets of London may be found vendors of Moss Roses which have been surrounded by a little Fern or their own leaves, and wired ready for the coat. The sale is immense, and good profits are gained by the vendors. The usual price is 1d. each, or a bunch of from eight to ten may be bought early in the morning for 6d. in the height of the Rose season."

A Garden in the Desert.—A gentleman owning large mills in a smoky part of one of our manufacturing cities has converted his premises (as unpicturesque in themselves as such premises usually are) into something resembling a fair garden. The sides of the mills are planted with Virginian Creepers, which stand the smoke admirably, having one advantage over Ivy—that they renew their leaves every year. All the spare corners of the yard are turned into beds or rockeries and planted with flowers suitable to the climate. The "hands" are also encouraged to grow plants in the windows, where they flourish as well as in private sitting-rooms. I wish that other masters would adopt the same idea, so that the ugliness and barrenness of our large towns, as well as the monotony of factory life, might be cheered even in a small degree by the introduction of a little natural beauty.—E. R.

THE SHRUBBERY.

The Cyprus Gum Cistus (Cistus cyprius).—This forms a hardy sub-evergreen shrub from 4 ft. to 5 ft. high, and produces flowers profusely in succession during the months of June and July. It is a native of the Island of Cyprus, where it grows on hills; it will, however, succeed in any good garden soil that is rather dry, and is easily increased either by means of seeds or cuttings. The upper surface of the

Gum Cistus (Cytisus cyprius).

leaves is smooth and deep green, and the under one clothed with hoary down. The branches are long, slender, and rather spreading, and the young shoots smooth. The flowers, which are produced in great abundance, are from 2½ in. to 3 in. across; they are five-petalled, pure white, with a dark rich brownish crimson blotch near the base of each petal, and orange-coloured at the base. The blossoms, in fact, resemble a large single Rose, but are of short duration, only lasting, in general, a single day. The fruit is a dry five-celled capsule, more or less covered by the calyx, and ripens in September. The Cyprian Gum Cistus forms a splendid plant for ornamenting rockwork or dry banks, but it requires to be fully exposed to the sun, as the flowers only expand under the influence of bright light. This species, which may be had from most good hardy plant nurseries, is known under the name of Cistus ladaniferus, C. l. planifolius, C. l. maculatus, and C. salicifolius.

Pruning Euonymuses.—There are few shrubs that are better adapted for edging beds or planting on sloping banks or margins of shrubberies than Euonymuses; but the beautifully variegated gold and silver-leaved varieties need constant watchfulness in regard to pruning away the green-leaved portions, or the latter quickly monopolise the strength of the plant, and the variegated shoots languish and eventually become overpowered. As, however, they may be looked over in a short time and the plain-leaved shoots removed, neglect in reference to this matter is inexcusable. As Euonymuses are easily raised from cuttings inserted under hand or bell glasses, I need scarcely say that it is important that the best coloured shoots should be selected for cuttings. Few plants are better adapted for pot culture than Euonymuses, and in districts where this beautiful shrub suffers from exposure a portion at least of the stock should be grown in pots so as to receive some protection in winter. A rather poor soil is the best for bringing out the leaf-colouring of the variegated varieties. —J. G.

Cutting Ivy and other Shrubs.—If cut or clipped before new growth commences, Ivy will present a very different aspect throughout the season from what it will do if deferred till new growth has commenced; therefore let it be cut at once. Hedges, screens, lines, or belts of shrubs that have to be kept clipped in a formal manner should now be operated on. Many common Laurels, Bays, and Laurustinus have been terribly injured by the severe weather; hence the pruning of these had better be deferred for a few weeks longer, till it can be seen as to whether or not they should be cut right down and allowed to break from the bottom. Any that now seem dead had better be headed back at once.—C.

Making Lawns.—If the weather be favourable, Grass seed should now be sown where it is desired to form new turf or renew old. The first condition necessary to ensure success is that the ground should be efficiently drained, and the whole surface broken up to a sufficient depth to allow of its being levelled, great care being taken that, should any portions require a considerable amount of filling up, the soil be well rammed in thin layers. This would occur in filling up trenches where drain-pipes have been laid. Where the surface is composed of gravel or poor soil, it is desirable to give a dressing of good soil, at the rate of twenty cartloads per acre, or more where it is easily obtainable. Having spread this evenly over the whole area, it should be harrowed and rolled until thoroughly pulverised, and any large stones or other rubbish should be gathered off before the seed is sown. Although in favourable situations three bushels of seed is considered ample to sow per acre, I am of opinion that not less than four bushels should be the quantity sown. Care should also be taken that the seed is of good quality. From 1 lb. to 5 lb. in weight of white Dutch Clover, mixed with the quantity of Grass seed recommended to be sown per acre, will be found an improvement on dry soils. After the ground has been prepared in the manner described above, the seed should be sown evenly over the surface. To do this a calm day must be chosen; this done, the best way, without exception, with which I am acquainted, to bury the seed is to use steel forks, drawing them backwards and forwards until the seed is properly covered. This any ordinary workman will do; neither harrowing nor raking will bear comparison with forks for this purpose. A light bush harrow or a flat bundle of sprayey Pea-sticks may then be drawn over the surface, and all stones, sticks, or other rubbish that may have turned up picked off, and, lastly, the whole area thoroughly rolled; in fact, the surface cannot be too much consolidated, unless it be of a clayey nature. Lawns treated in the above manner are sure to succeed, and, with favourable weather, may be fairly green in about a month.—C. D.

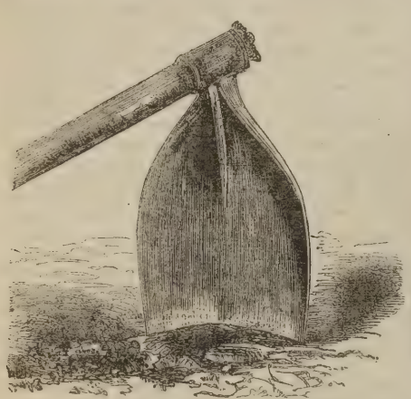
FRUIT.

UNPRODUCTIVE FRUIT TREES.

My fruit trees for years disappointed me in not bearing any fruit. I accidentally discovered the cause and the cure—at least in my own case, and I am disposed to think it is everywhere alike. When I planted, about thirty years ago, a young orchard, and laid it down in Grass, I planted between two of the rows of Apple trees a row of Black Currants. Not wishing to disturb the young turf, I put manure on the surface in autumn and spring without digging it in, and put it on fresh from the stable without the straw, in quantity not sufficient to smother the grass. From these trees I gathered prodigious crops of fruit for three or four years, till I removed them because they were out of place and unsightly. My other trees in garden and

orchard—Apples, Pears, and Plums—blossomed profusely, but set very little fruit. Indeed, of Pears I scarcely had a dishful a year for ten or twelve years. I then recollected my Currant bushes, and tried the same plan with my Pyramid Pears, covering with fresh stable manure the surface commensurate to the diameter of the bush, without digging in, early in the autumn, leaving the rainy weather to wash in and decompose it. My success was complete, and now all my fruit trees are served alike. I never fail to have a crop, whatever be the season. Of course, proper pruning must be applied as well, and judicious thinning of fruit early, to prevent alternate bearing. I am situated in a dry district, where artificial feeding must be resorted to in any case; but even in strong soils I am disposed to think the same plan would succeed equally well, and supersede the necessity of root-pruning, which is very troublesome. If the surface-soil remains undisturbed and well-manured, a fibrous mass will be formed on the surface naturally, which root-pruning aims at doing artificially, and the rich surface will have a tendency to draw the root growth upwards to the surface, which is very desirable. The cause of the shedding of blossom, I take it, is the want of strength on the part of the tree to set its fruit, resulting from the surface-digging, which destroys the most valuable of its feeding organs. It is only very rich soils that will enable a tree to bear well; it wants artificial nutriment of some kind, and by digging it in you at the same time take away in a great measure its means for taking it up. I used to manure in autumn and spring the surface soil about the trees, but the soil is now so much improved that I am not careful about more than an autumn dressing. In applying it, keep clear of the stem, and take care that there is nothing like piling manure about the tree; a thin dressing of 2 in. or so is enough. Care must always be taken to prune out all wood that gets decrepid and bark-bound. Manure will kill all Coniferous trees that I have ever cultivated unless applied very sparingly, as I have learnt to my cost.—H. W.

A Useful Garden Implement.—In gardens such an implement as the one here illustrated—which any blacksmith could soon



A Spade Hoe.

make—would be of great practical use in clearing shrubberies and plantations, as well as for earthing-up operations of all kinds. It must be well steeled along the cutting edge, and should be made strong and heavy enough to sever roots as thick as the wrist at a blow. It will then be found a really useful and practicable implement; a combination of the awkward old grub-axe with the hoe and spade, and invaluable for cultivating land near hedges and trees where roots are plentiful, and where the use of the common spade is, to say the least, extremely inconvenient. This implement pretty nearly represents a very useful tool in daily use in Kentish gardens; they call it a mattock-hoe, as it answers the purpose of hoeing, grubbing up roots, and digging at the same time; although a rude and simple-looking implement, it is surprising the variety of uses to which it may be put. In some parts of Kent the land is stiff, and orchard and garden crops necessitating a good deal of traffic on the soil, light tools, so useful on light sandy land, are comparatively useless; therefore tools of great strength have to be provided, and the spade or mattock-hoe is invaluable, as it cuts up the softest weeds or the stoutest suckers with equal facility. Another Kentish tool for breaking up or trenching land, or digging Hop gardens or orchards, is the "spud," or three-tined fork, the size and weight of which would alarm those accustomed to use light steel forks, but which the labourers in Kent prefer to a spade.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 22.—Top-dressing pot Vines. Grafting Gros Colman Grape on other stocks; looking over Apples in fruit room; disbudding Peaches in second house; sowing batch of Melons; potting and plunging Lilacs that have been forced; potting off Balm, and boxing Calceolarias; sowing Carnations, Picotees, Asters, Tagates, Love-lies-bleeding, and Prince's Feather; also Peas, Spinach, and a bed of Carrots. Planting Shallots and Garlic, first-sown Cauliflower plants, Lapstone Kidney and Early Handsworth Potatoes. Pricking out Onions; putting in more Coleus, Alternanthera, and Iresine cuttings; moving Artemisias, Oxalis, and Veronicas into cold frames, and annuals into cool Vineries; putting Cauliflower and Lettuce plants into cold pits; digging vacant land; forking among Gooseberry and Currant bushes; wheeling manure on Asparagus-beds; making a pit ready for Cucumbers; earthing up Cabbage plants; cleaning autumn-sown Onion-bed. Keeping orchard-houses in which the blooms are expanding at from 45° to 50° at night, leaving a little air on constantly; sowing Balsams, German and Ten-week Stocks; levelling down Celery trenches and getting the ground ready for Peas; re-making Mint beds; thinning out and cutting back Ivy on walls; sticking early Peas, and giving them a little earthing up; mending Box edgings.

March 23.—Putting in cuttings of Alternantheras and Mesembryanthemums; watering forced Asparagus beds with warm manure-water; turning over manure for Celery, having previously mixed with it salt and soot. Giving the surface of the Carrot and Beet ground a dressing of soot and preparing it for drilling; sowing Snow's Winter White Broccoli, Brussels Sprouts, and Wallflowers; potting Tomatoes and Capsicums; pricking out Celery and All the Year Round Lettuce; potting young show Pelargoniums for late blooming and small Violets in 8-in. pots; sowing Cockscombs, also Broad Beans, main crop of Parsley, and Long Surrey and James's Carrot; planting Red Cabbage and Globe Artichokes; dividing Dahlias; putting in Plumbago and scented Verbena cuttings, and layering Jasmines; thinning out Mignonette; pricking out Tomatoes; staking Peas; watering all permanent Peach trees in houses; manuring dwarf Roses; top-dressing Camellias with loam.

March 24.—Potting off Lobelia, Golden Chain and other Pelargonium cuttings. Shifting Tree Mignonette into 8-in. pots, using all manure with a top-dressing of loam and sand. Sowing Walcheren Cauliflower, Pine-apple Beet, and Myatt's Victoria Rhubarb; planting Aubrietia græca and Viola Cornuta; also Forty-fold Potatoes, Seakale, and autumn-sown Cabbage plants. Moving potted-off Heliotropes into greenhouse; placing pieces of Seakale roots (thongs) in shed to sprout; digging vacant land; hoeing among growing crops. Keeping Hamburgh Grapes which are in flower at from 66° to 68° at night, according to the weather. Planting the main crops of the following sorts of Potatoes, viz., Snowflake, Breadfruit, Main Crop, Giant King, Model, Schoolmaster, Porter's Excelsior, Paterson's Victoria, King of Potatoes, and Perfection Kidney. Sowing Cucumbers, also Canadian Wonder French Beans in pots. Planting out autumn-sown Cauliflower, also a few Brown Cos Lettuces.

March 25.—Preparing ground for new Seakale beds, and also for Globe Artichokes; earthing up Potatoes in frames; forking over the ground amongst Cabbage plants; getting netting and other coverings over Peach trees for protection; looking over fruit room, and removing any fruits that are decaying; tying in young shoots in Peach house; potting Stocks as they show flower; shifting young Fuchsias into 6-in. pots; sowing Seakale and Watercresses; planting out Lily of the Valley that has been forced; pricking out Celery plants; thinning out young Asparagus plants; and earthing up broad Beans.

March 26.—Potting Alyssum; sowing blue Larkspurs, Primulas of sorts, and Amaranthus; also Malta and Paris Cos Lettuce; likewise main crop of Celery, and putting it in Cucumber pit, placing glass over the pots; also sowing Chervil Radishes, and Meredith's Hybrid Cashmere Melon. Planting more Cauliflowers; putting in some Golden Willow cuttings; impregnating Primulas for seed; protecting Plums in blossom by means of netting; putting down covers over Green Gage Plum trees every night; searching for fly on Peach trees, and for thrips on Vines; watering Potatoes in frames; salting Asparagus beds. Digging border for Turnips, also flower borders; forking between Peas and Cabbage, and preparing beds for sowing Brussels Sprouts, Savoys, and Curled Greens. Earthing up early Melons with good stiff soil; also first Cucumbers, and training out the shoots. Earthing up Potatoes in frames; also Cauliflowers under handlights. Salting walks to eradicate Moss.

March 27.—Renovating linings round manure frames; weeding Box edgings and gravel walks; dividing and re-making herb beds; covering up Seakale beds; looking over Pelargoniums and picking off all dead leaves and stopping the shoots where required; clearing off borders, giving them a dressing of soot, and forking them up ready for sowing seeds. Sowing Yew berries and Perilla; also Melons, Cucumbers, Parsnips, and Turnips. Planting Carnations, Fairy Roses, and Gladioli; also Lapstone Kidney Potato, and rows of Cauliflowers between Early Peas; and dividing and replanting Pennyroyal. Pricking off seedling Petunias; putting variegated Pelargoniums into cold pits; preparing land for Sweet Peas; digging and manuring among Rhubarb stools; putting manure in ground for Hollyhocks.

Greenhouses.

Shading.—A house of any form facing the south, where the sun in the middle of the day comes directly upon the occupants, needs shading for a time on the sun-exposed side for almost any kind of plants; whereas, in the case of structures placed in the opposite direction, the bars and rafters break the force of the sunshine, and this, coupled with its striking them obliquely, much reduces the necessity for shading. Large numbers of tender-leaved, fine-foliaged plants, such as Cyanophyllums, Caladiums, Alocasias, Palms, and Ferns absolutely require shade when the sun is powerful, as otherwise, if the foliage be not positively burnt, it gets so brown as to make it unsightly. It is much the best plan to put those plants, both flowering and fine-leaved, that want shade, at one end of the house, using shade there only. It cannot be too often impressed upon beginners in the cultivation of plants that the blinds in all cases should be movable, and that they should never be down before there is absolute necessity for it, nor to fail in rolling them up as soon in the afternoons as they can be dispensed with. The material used should also not be thicker than just to break the force of the sun's rays.

Achimenes and Caladiums.—Achimenes for late blooming that have not been started should at once be put into heat. Those first started in pans will shortly be ready for placing in the pots or hanging baskets in which they are to be grown. For large houses there is nothing more effective than these plants in good-sized wire baskets suspended from the roof. For general purposes pots of small or medium size will be found the most useful. Their rapid growth necessitates a liberal supply of water through the growing season, for which reason see that the drainage is efficient. Any Caladiums not yet started should immediately be shaken out and repotted. These will be serviceable, retaining, as they do, their leaves fresh and in good condition through the autumn. If there be a deficiency of any kind when the young crowns have got 6 in. or 8 in. in length, they may be cut out from the tubers, placed singly in small pots, and treated as is usual in the case of cuttings, in which way they will shortly get established.

Propagation of Fine-leaved Plants.—Cuttings of Cyanophyllums, Aralias, Crotons, Dracænas, Ficuses, &c., should be taken off as soon as they are large enough for the purpose. In the case of most of them the young shoots that are formed after heading back root much more readily than the points of the strong branches, especially when obtained with a heel, as they can be got at this stage of their growth. All the larger-leaved plants of this description require sufficient room in the cutting-pots, or they are liable to damp off; and every effort should be made to retain in perfect condition the whole of the leaves which they possess, as upon being clothed with perfect foliage down to the base depends their appearance afterwards. Plants that require to be increased by division of the crowns are easiest managed about the time when they commence growth. Some of the species of Pandanus, Musas, Hedychiums, Cyperus, Anthuriums, &c., may therefore now be divided as wanted, potting the pieces separated singly and keeping them close until they have become established.

Ardisia crenulata.—Both the red and white fruited varieties of this plant, when well managed, are amongst the most useful berry-bearing subjects which we have. Where young shoots are obtainable they should now be propagated, putting them separately in small pots, or, if in larger numbers together, taking care that they are so treated that whatever leaves they possess may sustain no injury. For room decoration they are deservedly great favourites, lasting, as they do, with care in good condition for months. If considerable numbers are wanted, it takes some time to get up a stock from cuttings, and beautiful plants may be raised from seed, which if sown now in pots or pans, drained and filled with open sandy soil tolerably compressed, the seeds slightly covered and placed in a brisk growing temperature, after some time the seedlings will make their appearance, but

they are slower in all stages than many other plants.

Bouvardias.—A sufficiency of cuttings should at once be got in; they will succeed either made from the roots or shoots; where enough of the latter are not at hand, a good-sized plant or two will provide a number of the former, using the stronger pieces in bits from ½ in. to 1 in. long, putting them in pots or pans partially filled with sandy soil, the upper portion being sand alone, and inserting them about level with the surface of the material. If kept moist and warm they will soon commence to grow, and they should be placed singly in small pots as soon as large enough to handle.

Azaleas.—Those that have done flowering should at once be placed in a warm house and kept syringed to encourage them to make growth. Previous to putting them into warmth they should be closely looked over to see that they are free from thrips; should any trace of these be found the plants ought to be either fumigated or be dipped or syringed in Tobacco water. Any that require larger pots it will be better to defer moving till some further progress is made in the growth of the young shoots, as until this takes place the roots of Azaleas do not begin to move.

Flower Garden.

Carnations and Picotees.—The Tree or perpetual-flowering varieties of Carnation require attention at this time; they produce plenty of blooms when aided by a warm greenhouse temperature. The stems should be tied to sticks, else the weight of the flowers bends them down, and they snap at the joints. Some of the large full flowers are very beautiful, but nearly all of them burst the calyx unless it be tied round with a strip of matting before the flowers open. See that a goodly number of cuttings of all the varieties are put in for flowering from January to June next year. The very smallest offsets, if inserted in sandy soil, will soon form roots on a gentle hotbed.

Hollyhocks.—Instructions as to planting out choice-named varieties have already been given; see, therefore, that this operation is carried out as soon as the plants have been inured to the open air. Later propagated plants should be placed in cold frames when they have become well established, and they must also be speedily hardened off. For ordinary decorative purposes seedlings make the best display; and if the seeds be saved from the finest double flowers there will be comparatively few inferior varieties amongst them. If the seeds be saved from varieties of decided colours without crossing, the seedlings will vary but little from their parents, and half of them will be as good.

Pansies.—A few pots may be removed from frames to the greenhouse, where their agreeable perfume and rich colours will be appreciated. They ought not to be placed there until they are in flower, as if at a distance from the glass the growths soon become drawn up weakly. Cuttings may now be put in to produce late flowers of a better quality than can be obtained from old plants. The flowers of show Pansies very speedily deteriorate in quality unless all of them are picked off at frequent intervals in order to allow the plants to have a short rest. The growths ought to be thinned out, and the surface of the soil dressed with rich compost, when the young shoots may be pegged down over it.

Primula cortusoides and all Hardy Primroses give the greatest satisfaction when grown in pots under glass. The flowers can be inspected in all sorts of weather, and they occupy such a very small space, that they may find a place in the smallest gardens. We had a small bed of Primula cortusoides which stood out without any attention for several winters; but the plants were ultimately lost. We are now planting out a bed of the white, lilac, and red forms of P. amœna; planted at this time, they will flower as strongly as the plants in pots.

Delphiniums, Phloxes, and Pyrethrums in Beds, if they have not been replanted, should now be attended to without delay, as some of them have made considerable growth. Delphinium seeds, if sown now in heat and well attended to, will produce flowers in succession to the old established plants. D. formosum and D. Madame Henry Jacotot are two of the very best; these seeds should be sown in spring. The one has bluish-purple flowers, the other blossoms of a beautiful clear light blue.

Fruit.

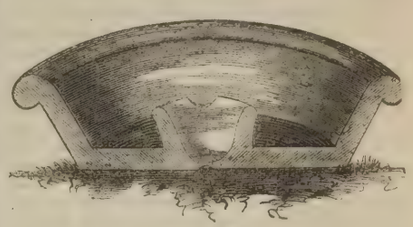
If pruning of all kinds, staking, tying, and nailing be finished, as by this time they should be, attention must now be directed towards devising ways and means for protecting the trees when in blossom. Though the trees are backward, any grafting that has to be done had better receive attention at once, for the double reason that there is now more leisure for doing it, and that it is very probable that when warm weather sets in growth will be very rapid, and, consequently, a good grafting time be very limited. Any trees that are languishing through poverty of soil, or over-fruitfulness, may be rendered vigorous by now removing the surface soil right down to the roots and replacing the same with good maiden loam and a liberal admixture of well-decayed manure. Well press the soil right down to the roots and finish off by a thick coating of manure on the surface as far as the roots of the tree extend. The surface-dressing and manuring of Raspberries should no longer be delayed. No hardy fruit so soon shows the good results of manurial dressings or gives better returns than the Raspberry; and this fact should be an incentive to the accomplishment of the operation. Thin out straggling branches or boughs, and eradicate the suckers from round about the stems of Nuts. The value of the sticks thus removed for various purposes will pay for the labour, not to mention the benefit accruing to the trees, as root-suckers are little better than parasites, for they live on the vitality which would otherwise aid in the production of more or better fruit.

Vegetables.

Onions, Parsnips, Early Horn Carrots, Peas, Broad Beans, Radishes, and Lettuces should now be sown; and a good batch of early Potatoes, Shallots, and Garlic be planted. Every endeavour should be made to bring up arrears of work, the result of the long winter. Preparation should be made for planting the principal plot of Potatoes; deep tilth, moderately enriched soil, thorough drainage, head-room for the haulm by planting the tubers a good distance apart, and medium-sized seed tubers with but two sprouts, constitute all that is required in order to ensure success. Peas and Broad Beans should be sown successionally, according to the demand. As a rule, as soon as one lot emerges above the soil another should be sown. Earth up and stake Peas, and on the cold or windward side screen them with Laurel or other evergreen boughs. Sparrows and chaffinches at this early season have an insatiable taste for the tender tops, and when once they commence their attack nothing short of annihilation will deter them. Radish, Turnip, Broccoli, and Cabbage seeds are equally dainty morsels to these pests, and, unless netted over as soon as sown, woe betide them as soon as the first chaffinch finds them out.

Cauliflower plants wintered in hand-lights should now be finally thinned out, about three of the best being left to mature on the ground; the remainder should be carefully removed with balls of earth, and planted in the warmest available position. A deep drill helps to ward off cutting winds, and as soon as the plants get sturdy it can be filled in level, and no other earthing up is required. Prick out Cauliflowers sown in heat a few weeks ago; a south border and a little evergreen branch protection are all that is required. Such plants will make a good succession to those now being planted. Brussels Sprouts and early Cabbages should be treated in a similar manner. The heavy work now requiring attention will be the digging out of Celery trenches, clearing off stems of Broccoli, Brussels Sprouts, and other winter greens, and preparing the ground for Potatoes, Spinach, Peas, Runner Beans, and the like. Let all the walks and edgings be put in good order, and maintain neatness at all times by arranging that wheeling over the walks or all other heavy traffic be done during the prevalence of drying winds.

Pot Saucer.—The accompanying woodcut represents a garden saucer of considerable utility. As will be seen, it is really a circular trough, the pot standing on the inner rim. The centre, however, is not open, but a cup into which the overflow from the rim and the drainings from the pot escape and pass away through a hole in the bottom. Into this central cup some roots descend and find moisture. The advantages of this saucer are that it keeps the plants moist, without subjecting them to saturation; it allows of frequent waterings with fresh water without inducing rotting or stagnation of the soil. The common garden saucer, judiciously used, is a great aid to the cultivator, and answers perfectly for many purposes; but this has special value in many



Saucer for Plants.

cases where the other would be worse than useless, and it deserves general adoption in gardens where many plants are grown. It is made by Messrs. Down & Harlock, Cheam, Surrey.

Rustic Baskets.—To those who appreciate a really pretty rustic basket, allow me to recommend Wych Elm rods for their manufacture. The bark being thick, wrinkled, and deeply serrated, resembles that known as virgin cork on a reduced scale, without being so heavy in appearance. The heart of the rod is tough, and the bark never seems to have a tendency to crack or peel off it even when exposed to a temperature under glass of from 80° to 100°, *i.e.*, when the baskets of which it is made are used to hold plants in pots. I have not tested them with loose soil, but have no doubt of their proving satisfactory. The rods can be obtained of wattled fence or common hurdle makers, and are very cheap. One rod of, say, 8 ft. to 10 ft. in length, and from 1 in. to 2 in. thick, on an average, will make a basket quite large enough to hold a fair-sized pot. If required, such rods can be delivered split up the middle. Nothing more is wanted for making up such baskets but some small galvanised or copper wire, and they stand a vast amount of wear and tear.—F. M.

Siebold's Stonecrop (Sedum Sieboldi).—This is a dwarf and creeping form of the Stonecrop, admirably adapted for planting on little rockeries, on the tops of old walls, or as an edging to raised beds or borders. Grown in pots or wire baskets it also makes an excellent

Siebold's Stonecrop as a Basket Plant.

room plant. It requires well-drained, rather loose soil, and a not too liberal supply of water. Its flowers are rose, tinged with purple.

Birds and Seeds (1536).—Red lead is not dangerous, provided the hands are washed after sowing the seeds. I use it every spring and find it most effectual. Place the seeds in a saucer or basin, pour just sufficient water over them to damp them and cause the lead to adhere; then sprinkle the lead over the seeds, and stir them about till all have taken on a coat of red, adding a little more lead if it be necessary, to dry up all the moisture. The proportions need not be exact. As the lead will not affect the germination, simply use sufficient to make each seed look red. Soaking the seeds in paraffin oil has also a deterrent effect.—E.

House and Window Gardening.

Primroses as Window Plants.—The Primrose, both single and double, is deservedly a favourite garden flower, but its value as a pot plant for window decoration is not perhaps so well known as it should be. There is not the slightest reason why our dwellings should not be made gay with this charming spring flower at an earlier period of the year than it comes naturally into bloom in the open air. Primroses are impatient of forcing, but they flower beautifully in the window of a cool room, and expand their pretty bright blooms as well, and oftentimes better, than when in the open ground. Nor are they particular as to aspect; according to my experience they thrive quite as well in a north window as in one more fully exposed to the sun. It is this latter quality which renders Primroses especially valuable, as we really find but few plants which during February and March will grow and flower freely in a north aspect. Many apartments which at this season of the year present a rather dreary appearance might be effectively and inexpensively enlivened by filling their windows with Primroses; and the most satisfactory part of the matter is that Primroses not only live there, but the owner has the pleasure of seeing them grow, expand, and develop fresh beauty every day. It lies in the power of every one to render their homes bright and pleasant in early spring by means of these ever-welcome flowers. By planting them out during summer in good soil in a sheltered situation and keeping them well watered they may be lifted with good crowns and roots, placed in 4-in. and 6-in. pots, and stored in a frame, or in some sheltered spot where they can be protected during severe weather, from thence to be introduced in spring into the situations which they are intended to beautify.—J.

The Killarney Fern Indoors.—I have read with interest several letters on the subject of the Killarney Fern (Trichomanes radicans), and mine, I think, ought to be mentioned, as it measures 11 ft. 8 in. in circumference. It was given to me about twenty years ago, with one or two fronds, and it has always been grown in a glass-case in the drawing-room, or rather in a succession of cases, as it has often outgrown its home. The case has doors at the side, which are opened when visitors come to admire the Fern; and I water it overhead whenever the fronds have no damp on them. The superfluous water drains into a kind of little tank under the bottom of the box in which the Fern grows, and this tank has a tap to draw the water off. I find it rejoices in a liberal supply of bits of sandstone, over which its rhizomes creep much more readily than they do over the earth into which it is supposed to send its roots.—M. D.

Stonecrops and Houseleeks in Windows.—Happening to pass through a thickly-populated district during the recent severe frost, my attention was directed to a collection of plants grouped on the window-sills of a dwelling, and which, notwithstanding the intense cold, presented as fresh and bright an appearance as if growing under more favourable conditions. Is it not strange, and matter for regret, that the pretty little neat-habited Stonecrops, so hardy in their nature, and which may be so grown as to completely drape and hide from view the bare sides of the pots, should not be more extensively grown for open-air decoration during the winter months? Their culture is so exceedingly easy that any one, having the accommodatien of a few square feet of space in an open, sunny situation, may grow them to great perfection. All that they need is abundant supplies of water in hot weather, administering occasional doses of pure liquid manure or soot-water when the pots get full of roots. During the summer months but little difficulty is experienced in furnishing the windows with flowers and verdure. The list of plants, however, which are sufficiently hardy to present a fresh, bright, ornamental appearance during protracted frosts is unfortunately very limited. Evergreens, even of the most robust kind, are apt to turn brown and dingy when exposed to the bitter drying winds which often accompany hard frosts, and which, freezing through and drying up the balls of earth, deprive the plants of their due supply of moisture, and with the consequent effect of causing the foliage to lose its lustre and freshness. To such trials the Stonecrops and Houseleeks are impervious; they remain, even in the most exposed situations, charmingly fresh and green the whole winter through. They may also be employed where plants of taller growth would be inadmissible. It is also fortunate that in both families we possess a considerable number of species capable of being thus used; consequently there is but little difficulty in forming a varied and most interesting collection.—J. C.

Grasses for Summer Vases.—We shall soon be able to avail ourselves of the bloom spikes and leaves of Grasses for the ornamentation of Vases, and doubtless I am not singular in entertaining pleasurable anticipations of the time when these graceful adjuncts to a bouquet are again at our command. When Camellias are over, Roses are nearly ready to take their place in our flower vases; when the long summer reign of these is coming to a close, Dahlias and Asters are at our call for similar uses; and these, again, are succeeded by Chrysanthemums, which carry us on until Camellias are ready for us again. But flower-spikes of Grasses, which are coming in during May, are at their best all through June, and are getting scarce towards the end of July; what is there, therefore, that can fill their place at other seasons of the year? Literally nothing;

Vase of Flowers and Grasses.

let us, therefore, make the most of them while they last. Grasses certainly have been more used during the last few years than previously for vases, that is, if the competitions for table decorations at our flower shows may be taken as indicating the style of the period. At the same time, I feel sure that they might be much more used than they have yet been. In the engraving which accompanies this it will be seen that Grasses predominate over all the other types of flowers and foliage; and the general effect can hardly be surpassed for grace and elegance. The fashion of the day to value plants more for their rarity than for their intrinsic beauty, will, no doubt, account for the want of attention that has hitherto been paid to many wild plants of common occurrence suitable for decorative purposes. There are many foreign Grasses of an exceedingly graceful character which might be grown in pots, and thus made available for conservatory uses as well as for bouquets and vases.—W.

A Simple Window Ornament.—Many persons know, but some do not, that a pretty and easily-grown window plant may be obtained by soaking a round piece of coarse sponge in warm water until it is thoroughly expanded. After squeezing it about dry, place in the openings Millet, Red Clover, and Barley-grass seeds, Rice, and Oats. Hang the sponge in a window where the sun shines a part of the day, and sprinkle it lightly with water every morning for a week. Soon tender leaves will shoot out, and growing rapidly, will form a drooping mass of living green. If regularly sprinkled, it will later be dotted with the blossoms of the clover.—*Glasgow Herald.*

Trailers for Window Boxes.—I have for several years grown a box of Mignonette, with Sweet Peas sown in a single row close to the outer edge of the box; Invincible Scarlet, black and white, mixed with a few of the Painted Lady. They droop over, and hang about 2 feet, completely hiding the box; and if the pods are clipped off as they appear they will continue to flower till the frost comes. They should be sown the beginning of March.—S. M. M.

Camellias under a Verandah.—It may interest some to know that Camellias thrive and look well under a verandah. We have some doing remarkably well and full of healthy buds as large as small Nuts. They have protection from frost only.—W.

A Fine Window Plant (Dielytra spectabilis).—If at this season, when this plant is pushing up its early growths, good strong clumps of it be lifted and placed in a warm window, they will soon make beautiful plants. Out-of-doors a very sheltered position should be chosen for this plant, as, starting early into growth, it is liable to suffer from spring frosts.—L.

Harrison's Musk.—This is a decided improvement on the old variety, and its scent is equally strong. It makes an excellent window plant, and at this season may be readily increased by division of the roots, or by means of cuttings.—G.

GLASSHOUSES AND FRAMES.

Culture of Stephanotis floribunda (1570).—The Stephanotis is propagated by means of cuttings of the half-ripe wood inserted in silver-sand and placed in a close hand-light, in a warm house, until rooted. If the pot can be plunged in bottom-heat, such as a mild tan-bed, the formation of roots will be much facilitated. Every morning give air for about an hour, and preserve the sand in a moist condition. The following March prepare some well-seasoned fibrous peat, taking care that it is, when used, of the same temperature as the house, and pot the cuttings off into small pots. Water very gently, keeping them in a temperature of 55° by night and from 60° to 65° by day. As soon as the pots become filled with roots, shift into 4-in. pots. Place three stakes round the edge of the pot, and train the shoots to them as they grow. During the growing season, maintain atmospheric humidity by frequent syringings in hot weather, and by damping down the paths of the house. By the middle of August growth will have ceased, and from that time forward until the advent of cold weather free ventilation must be given, with the object of thoroughly ripening the wood. The Stephanotis will thrive very well amongst an ordinary collection of stove plants, but will flower much more freely if placed during the late summer and autumn months in a cool structure. One good point in the culture of this plant is to give a distinct period of rest, which is best afforded by wintering the plants in a temperature ranging at 50° by night and 55° by day. When planted out—and in this manner better results are obtained with less trouble—the shoots should be trained near the glass, merely affording shade enough to prevent scorching. Where a walled-in front border or a centre bed exists, there is no difficulty in making good provision for the roots. Some 6 in. of brick rubble should form the drainage, and the compost may consist of half peat and loam, adding thereto some silver-sand and a little crushed charcoal and pounded brick. Plant out in March, watering carefully until good growth is made, when copious supplies will be needed. If pot culture is preferred, shift about the middle of February into 8-in. pots, using the compost recommended for planting out. Affix a balloon-shaped trellis (which may be easily made with thin hazel rods), shorten back the shoots to about two-thirds of their length, and train as required during the growing season. Mealy bug is often very

troublesome, and must be kept under by means of frequent spongings.—J. C. B.

HOW TO GROW CELOSIAS.

There are many fine flowering annuals for both out and indoor decoration, but I know of none more ornamental or useful than the Celosias. They may be had in flower from June to January, and during all that time they may be used for room or conservatory embellishment with excellent effect. They have no scent worth mentioning, but the colours of the flowers are both interesting and varied. As with other annuals, there are many strains of Celosias; some exhibit a good deal of the Cockscomb style, others form long narrow inflorescence; but the best produce plumes more feathery than the finest heads of Pampas Grass. It may be said these are the only kinds really worth growing, so very much superior are they to all others; but the worst of it is they are rather difficult to secure. The best way is to buy a mixed packet of seed, grow the whole well, and save seed only from the very best; we thus improve the strain, especially if seed be saved in this manner year after year. Celosias produce seed freely; but, as is often the case, the best are always the shyest in this respect. When the flowers show signs of decaying, the plants should be placed in some warm, dry, airy house, to prevent them from damping and to ripen the seed. This should be gathered a little before it is fully ripe or it may drop out. The best, or, in fact, the only, mode of propagating the Celosia is from the seed. It may be sown from February to July, firstly to produce early plants for midsummer and autumn blooming, and lastly for plants to bloom late in autumn and midwinter.

The seed may be sown either in pots or pans; we generally use 8-in. pots for the purpose. They are filled quarter full of crocks, over which is put some rough material, and the remainder is made up of a mixture of loam, leaf-soil, and sand in equal parts. This compost is made moderately firm, the seed is sprinkled thinly on the surface, and then covered over with a little of the same mixture; a gentle watering is then given, and the seed soon germintes in either a top heat of 60° or a bottom-heat of 70°. Under the latter treatment the young plants come up sooner, but healthy young seedlings may be secured both ways. As soon as the young plants are about 2 in. high they are carefully lifted and potted singly in 3 in. pots, using the same kind of mixture as that in which the seed was sown, and giving them the same temperature, &c., as before. From this time onwards there is only one pest that is to be guarded against, and that is the red spider; it is particularly fond of the Celosia, and very often spoils the plants when not checked. When young the leaves may be sponged if there be any sign of spider; and, as the plants become large, frequent syringing will keep it in subjection.

As the young plants gain size it will be found that the pots soon become filled with roots, when a shift into larger pots must be given, the size being determined by the amount of roots; previous to flowering, care must be taken that they never get pot-bound, for when that occurs they invariably start into bloom, thus affording a certain means of flowering them at any time, and in any sized pot. From 3-in. pots they should be shifted into 5-in. or 6-in. ones. Fair-sized plants may be bloomed in the latter size, and when they are wanted for small vase decoration this size will be found very useful. After being taken from the 3-in. pots, well-decayed manure should be substituted in the potting compost for the leaf soil, as Celosias are rather strong-feeding plants. When they have been potted a second time they may be again placed in a mild close atmosphere, but after the beginning of June they succeed very well in an unheated frame, where, being near the glass, dwarf sturdy plants are the result. They may be placed in the conservatory or window just as the flowers are forming, but they should not be taken into a room until they have nearly or quite expanded, and the time during which they remain in bloom will surprise people not acquainted with them. Three months is not an unusual time for them to retain all their good properties in this respect; owing to this, plants which come into bloom in July will be found in the same condition in the beginning of October, and plants just coming into bloom in October will remain so until after the new year. The latter stock of plants should be kept hardy—that is, not grown in a close warm place. but in frames fully exposed to the sun.

The younger and more vigorous the plants are during the short days, the better do they bloom and withstand a low temperature. When in flower, especially in winter, they do not require much heat; a temperature anywhere between 35° and 60° suits them. What they want more than heat is a dry atmosphere, as damp soon rots the feathers. It is chiefly on this account that they succeed so well in rooms. I have also found them to last a very long time in church decoration, a point of importance in the case of those who (like ourselves) have to decorate the church nine months out of twelve. If any one imagines that Celosia culture is a difficult matter, let me assure them to the contrary; no plants are more easily grown, and none will yield a better return for attention paid to them, whether that be much or little. D. E. L.

Forced Shrubs.—It may be well to tell the inexperienced that when hardy shrubs that have been forced are taken out of conservatories, &c., they should not be placed out-of-doors under shrubs, or in any out-of-the-way place; on the contrary, they should be put into a greenhouse or frame to make their growth before being put out. Thus treated, they will force much more easily the next season. Some Rhododendrons thus managed for four years have done good service, and the same may be said of Ghent Azaleas.—J.

Iris reticulata under Glass.—I have just had a bunch of this beautiful Iris sent me by an amateur who grows it at this season of the year in his greenhouse. It is not the freest flowering variety of the Iris tribe; but he informs me that he has a quantity of it in flower at the present time- I need hardly state that Iris reticulata is perhas the most beautiful of its class; but I have never seen such fine and perfectly developed flowers of it as those just referred to, and I should say the plant would be a most desirable addition to our forcing plants, if growing it in a greenhouse can be called forcing. The flowers are of a deep blue colour, with a bright golden blotch on the lip, shading off to white at the edges, and also spotted with purple. It is even superior to many Orchids.—S.

PRIZES FOR ASPARAGUS.

Sir Henry Thompson has offered to add five guineas to the prizes offered some time ago for Asparagus. The object of these is the improvement of Asparagus by the adoption of the French system, which is a much simpler and less expensive one than that now in use. The first competition will take place next spring at the Bath and West of England show at Tunbridge Wells; and the exhibitions will be continued during seven year, severy year in a different locality. Mr. S. Spalding has also promised five guineas, to be given as an extra prize the year the exhibition is held in Kent. The Hon. and Rev. J. T. Boscawen has given an extra prize of five guineas, to be competed for at the first competition. M. Godefroy-Lebeuf, of Argenteuil, near Paris, offers the sum of £10 to be distributed in prizes. Apart from these sums, over 100 guineas will be given in prizes.

The Plumy Cockscomb (Celosia pyramidalis).

The details of the French system of growing Asparagus are so very clear that they may be shortly stated. Each plant is treated as an individual, requiring much space in which to grow. Experience has taught cultivators that a smaller space than 4 ft. apart will not suffice to give the best result. People might suppose that this means a waste of ground, but it is not so; when the plantation is young, waste of ground is avoided by planting a light crop between the lines—say one of Kidney Beans or of early Potatoes; but after two or three years' growth the Asparagus roots occupy the whole space; and the result is so much more satisfactory than in the common way that the ground affords a more satisfactory return. There are two principal ways of securing crops—one being devoting a certain portion of ground to the crop, as usual

with us; the other alternating plants between small fruits, or placing a plant wherever there is room for one. This last way is highly important, because it may be carried out in small gardens. Healthy yearling plants are always chosen, and they are planted about the time when growth commences in spring. They are invariably planted in a shallow trench, somewhat like a Celery trench.

In this trench, about 8 in. deep, the plants are placed on little low hillocks, and they are carefully attended to for the first year. The plants, be it noted, are 4 ft. apart in the line, and 4 ft. apart in the trench. In soil of ordinary quality no manure is used at the time of planting. There are soils in which drainage and preparation might be required; but assuming that the soil is as good as garden soil generally is, no preparation whatever is given beyond planting each root in a handful of fine surface-soil; therefore the great expense which has been supposed to be necessary in the culture of this plant is, at the commencement at all events, avoided. It is when the plants begin to get strong and well established that a little manure is applied. There is thus a great economy in plants and in manure. During the coming two months is the best time to plant, using strong, clean, yearling plants.

ANSWERS TO QUERIES.

1502.—**Planting a Rockwork.**—If the situation is open to the west, so that the full afternoon sun will reach it, many kinds of herbaceous plants will thrive there better even than Ferns. Campanulas garganica carpatica, Arabis lucida variegata, Draba azoides, Lithospermum prostratum, Stonecrops of sorts, Saxifraga longifolia and Phlox frondosa would all be suitable subjects for the purpose. If, on the contrary, high trees or a wall overshadow the place, Ferns would give the greatest satisfaction, with which might be associated such shade-loving subjects as Saxifragas sarmentosa and umbrosa, and Nertera depressa. We would also plant here and there a few Snowdrops, winter Aconites and Crocuses, as well as a few Primroses and the pretty Primula denticula, which like a sheltered situation. A pretty edging to the rockwork may be formed by meaus of the small-leaved variegated Ivy, which presents at all times a charming contrast to Ferns and such-like plants.—C. B.

1520.—**Red Spider on Vines and Peach Trees.**—There is but little difficulty in preserving plants from the attacks of the red spider, providing timely measures are taken. Growers should always bear in mind that this pest luxuriates in a hot, dry atmosphere, and that where the plant is healthy and the proper atmospherical conditions are maintained it cannot multiply to any serious extent. In the first place, as soon as the Peach trees and Vines are fairly in growth, make a point of putting a little sulphur in the water used for syringing. Work the sulphur in the form of a paste, it will then readily mix with the water. A 2½-in. pot of sulphur will suffice for a house 50 ft. long. In the case of the Peach trees, work well with the syringe into the under surfaces of the leaves. It is there that the enemy congregates. Many syringings does not suffice. One good washing in the manner recommended every week should preserve both Vines and Peach trees from the attacks of this pest. Take care that the latter gets plenty of moisture at the roots; it may be that it suffers a little in this respect. Dryness at the roots, accompanied by an arid atmosphere, are sure to breed the spider to a serious extent. —J. C. B.

1571.—**Greenhouse in Town.**—Soft-wooded flowering plants, such as Geraniums, Fuchsias, Lantanas, Lobelias, Petunias, Heliotropes, and Tropæolums, would bloom very well in such a structure during the summer months. Begonias Weltoniensis and Dregei are very pretty free-flowering plants. We would also recommend the formation of a small collection of succulents of various kinds, amongst which may be specially mentioned Echeverias metallica and retusa, both winter-flowering plants. One or two Camellias and Indian Azaleas might also be included in the list. If the house is freely ventilated during the summer months they will succeed fairly well. We would also recommend the addition of a couple of well-furnished hanging baskets, for which Ivy-leaf Geranium l'Elégante and Tradescantia zebrina are excellent subjects.—C.

1709.—**Growing Mushrooms.**—If the permanent cover interferes with the arrangements for properly covering the bed, to maintain the requisite temperature remove it, and trust entirely to coverings of litter and mats to keep off rains, &c. Procure sufficient fresh stable manure to make a bed, when trod down firmly, from 15 in. to 18 in. thick. If made in the form of a ridge, it may be 18 in. or more in the centre, and taper down to the edges. Shake out the short manure from the long litter, if there is much of the long litter mixed with it; but if not, mix all together. Let it remain on the heap to ferment for a week or ten days, but permit no rain to fall on it. The fermentation is to carry off any rankness, and prevent over-heating when the bed is made up. At the expiration of the time mentioned turn it over, mixing the outsides with the centre, and leave it again four or five days. Then shake it up again and make up the bed as firmly as possible. Place a watch stick in it, and spawn when the temperature of the bed is about 75°, or 80° with no indications of its rising higher. Guard against the temperature of the bed falling below 60° by increasing the thickness of the coverings of litter should it be necessary. Until the spawn is used it should be kept in a perfectly dry place, as it will run and exhaust itself if it be the least damp.—E. H.

1743.—**Culture of Kalosanthes.**—These are very easily cultivated and flower very freely. Cuttings put in early last summer should flower well in June this year. The reason that they do not flower is probably that the plants have been grown in a dark, badly-ventilated part of the greenhouse. The plants should be placed in the full sun all through the season near the glass, and they also enjoy plenty of fresh air. Treated thus they flower very freely; and it is best to grow up a succession of plants and throw away those that have flowered. A specimen may be grown 12 ft. in circumference in two years, and will form a dense mass of flowers; but it will only do so well once.—J. D.

1745.—**Cucumber-growing in Warm Greenhouses.**—Turfy loam, as full of fibre as possible, and about one-third old hotbed manure or leaf-mould mixed with it, will grow Cucumbers well. Train up the leading shoot unstopped till it has nearly reached its full limit, but pinch in all laterals one joint beyond the fruit. If too thick, some of the laterals may require removal, but do as much of the pruning as possible with the finger and thumb. Take 65° as the mean night temperature, but for summer the question of temperature is not so important, as plenty of Cucumbers are grown without artificial heat at all after May, by shutting up the house early, with the sunshine inside. Maintain a moist atmosphere by sprinkling water about the laths and walls. When bearing freely give liquid manure twice a week. Place the sheep manure in a tub, fill it with soft water, well stir it, and when settled it will be excellent for Cucumbers in bearing. In the pruning of Cucumbers keep the growth thin enough to do justice to the foliage.—E. H.

1744.—**Manuring Crops.**—The mixture of stable manure and guano is suitable for Gooseberry and Currant bushes; guano is not so good for Potatoes; phosphates are better. Carrots and Parsnips should have no strong manures given to them, but the mixture would suit Onions and Turnips. The stable manure will be better dug into the land in winter, and the artificial compounds applied as a top dressing, or in a liquid form after the plants are up—about four or five pounds to the square rod, according to its quality. Guano should be applied cautiously to Peas, if at all. Cabbages are gross feeders, and for them anything in the shape of manure is suitable. Salt is a capital manure, especially for light porous soils.—E. H.

1734.—**Effects of the Weather.**—Cut back the Aucubas early next month to living wood. They will all break again. In the severe winter of 1860-61 many of our Deodars were killed to the snow line, but they all broke again, and many of them made handsome specimens and are still doing well. Do not be in a hurry in cutting down; see what life remains. When the dead wood is all cut out, select a new leader, and assist it to become erect by some mechanical contrivance; a stout stake will in most cases suffice.—E. H.

1749.—**How to Make a Herb Bed.**—The best time to make herb beds is in April. Where the soil is good the question of aspect is not so important. The following are indispensable: Thyme (common and Lemon), Sage, Mint, Tarragon, Winter Marjoram, Fennel, Balm, Chervil, and Parsley. Sage and Thyme may be increased by cuttings or seeds, the former preferable; Mint, Tarragon, Marjoram, Balm, and Fennel by division of roots, although the latter is easily raised from seeds sown now. Chervil should be sown now, again in a month's time, and again in August for winter. Parsley should be sown now, and again in middle of July. Annual Herbs, such as Basil, Sweet Marjoram, and summer Savory, sow in a gentle hotbed in April and plant out in May; or sow the seed in a warm position in the open air in the latter month.—E. H.

1564.—**Roses for Low Walls.**—Maréchal Niel, Climbing Devoniensis, Duchess of Edinburgh, and Souvenir de la Malmaison, are amongst the finest of the climbing Roses. They are vigorous growers, and should be planted quite 6 ft. apart, so that the shoots may be trained horizontally.—B.

1566.—**Propagating Tacsonias.**—Take free, healthy cuttings of the half-matured wood, cut them to two eyes, and insert them deeply in sandy peat. Place in a hand-light or frame; keep close and moist until roots are emitted. From the middle of July to the middle of August is the best time for taking the cuttings.—J. C. B.

1572.—**Flowering Plants for Fernery.**—If the Ferns are in a close glass case it will be useless to attempt to grow flowering plants with them. If they are in the open air, Primulas, Saxifrages, and flowering bulbs may be planted amongst them. The Canary Creeper is of quick growth and flowers freely.—C.

1575.—**Propagating Berberis Darwini.**—This handsome flowering shrub is easily propagated by means of seed. Sow at once in pans of loam and leaf-mould; place in a cold frame, covering with a pane of glass until the seedlings appear above ground. Then gradually inure to the open air. We should not suppose that the berries are hurtful; the fruits of its congeners, dulcis, aquifolium, and the common Barberry, are comestible.—C. B.

1559.—**Plants for Greenhouse.**—For a select list of the best and most useful Pelargoniums and Fuchsias I would refer "Amateur" to p. 804, Vol. I. Any of those there named cannot fail to give the greatest satisfaction. Golden Gem, Bijou, aurea, floribunda, and Little Beauty are good varieties of Calceolarias. Rose Maréchal Niel, Tacsonia Van Volxemi, Passifloras Impératice Eugénie and Campbelli, and Lapagerias alba and rosea are amongst the best of flowering climbing plants.—J. C. B.

1510.—**Flowering Evergreens for Walls.**—We know of nothing to equal the Magnolia grandiflora for this purpose. There are the evergreen Roses, which, however, lose their freshness in severe weather, whereas the Magnolia when thus placed remains in good condition the whole year through. Procure the Exmouth variety, which flowers in a young state.—B.

1576.—**Camellias Failing.**—It is really difficult to assign a reason for the Camellias failing in the manner described, and only very bad treatment could produce such disastrous results. Have the plants stood on an open stage over a flue, some unsuspected crack in which might have caused the damage? If the foliage was healthy when the plants were removed to the warm house, it is evident that they must have received a sudden and severe check, or they would not have gone bad in such a short space of time.—J. C. B.

1562.—**Flowers for Bouquets in June.**—We should think that the best plan would be to devote the house to Tea and other Roses and double Geraniums, which are welcome in all floral arrangements, and are specially adapted for button-holes. Mignonette might also be sown. There are many other choice flowers which would come in at that time, but which require to be grown one season for the purpose.—J. C.

1573.—**Pelargoniums Failing.**—It was wrong to shift the Pelargoniums in the dead of the winter. They should have been kept in small pots until they were fairly in growth. Allow them to remain as they are, watering very carefully. If the wood is sound, they will soon commence to break from the old stems.—C.

1574.—**Stephanotis Leaves Turning Yellow.**—We can only surmise that the soil has been maintained in a too moist condition. Allow it to dry out, and then water, each time just enough to moisten it through. Great care in this respect will restore the roots to health, and cause the formation of fresh fibre.—C.

1621.—**Sparrows Eating Lawn Seeds.**—Take pieces of bright tin, about 3 in. square; bore a small hole in one corner of each, and suspend them by light string tied to stakes at intervals over the lawn, so that they sway freely about with the wind, only just clearing the surface of the ground. The birds cannot stand this. The higher the support, and the more freely the tin sways the less they like it. A few at intervals of 10 or 12 yards over the lawn are enough. Any old pieces of tin will do cut up, but they must be bright.—SUB.

Weedy Lawns.—Coltsfoot is a very troublesome weed. About three years ago I found it a great nuisance. Where I could, I had it dug up; but where the soil was dry and light close to the house, I found it rooting 2 ft. or 3 ft. into the foundations. If a piece 1 in. long is left in the ground, the chances are that it will turn up alive. I therefore persistently beheaded every

one as fast as they appeared; and, when I could without injury to plants around, added a little salt to the cut stems. By this means I cleared my place in about two years. I should think if "Lover of Green Lawns" made free use of his roller and mowing machine, the Coltsfoot would have little chance of long life above ground, at any rate on his lawn.—RUSTIC.

1727.—**Cats in Gardens.**—If the garden is walled all round it is easy to keep out these pests by placing wire netting flat on the wall. When thus placed (with the consent of the neighbouring owners), the wire netting of about 1 yard width will be found to hang down a little on each side, and no cat in the world has any idea of how to get round the angle.—WITHYCOMBE.

1719.—**Raising New Zealand Flax from Seeds.** The seeds vegetate quite freely in a heated house or gentle hotbed. Sow thinly in shallow boxes, and when the plants are 6 in. high plant them out in the open garden.—J. D.

1728.—**Forcing Duc Van Thol Tulips.**—If these have been treated the same as Hyacinths every bulb ought to have produced a flower if they were well ripened last year. Forcing ought not to be attempted until the bulbs have produced a considerable proportion of roots, and then the temperature ought not to exceed 50° as a minimum to begin with.—J.

1730.—**Pruning Roses for Exhibition.**—To obtain flowers from Hybrid Perpetual Roses about the end of August, it would be necessary to prune them early, so that they would flower early to be cut over, in order that they may start again, and the second flowering would be about the end of August in an early season. It would be a mistake to allow the Roses to grow and prune so late that only one set of bloom would be obtained.—J. D.

1368.—Leopoldshal Kainit can be obtained here from J. Cadle & Co., Docks, Gloucester, and is a cheap manure, but unless properly used may not be of much benefit. I should advise you to read an article which appeared in the *Farm Journal* of November 25 last, by G. Embrey, of Gloucester, on the use of Kainit in agriculture.—G. N.

1754.—**Culture of Tuberoses.**—What is the latest month these will open properly in a temperature of 55°? Also, how long do the bulbs take to flower from time of starting? And what is to be done with the side spikes? Are they to be nipped off?—C. L. [They will open all the year round in the temperature you name. They take from three to five months to come into flower from the time of planting, according to the time of year and the treatment they receive. The side-shoots are best rubbed off if good blooms only are wanted.]

1755.—**Parffian for Roses.**—What quantity of paraffin to a gallon of water would make a suitable mixture for Roses?—H. W. [We, of course, presume you want the mixture for killing insects on Roses. A good wineglassful of paraffin to a gallon of water will be plenty strong enough. If the Rose shoots are very tender, half the quantity will be enough.]

1756.—**Dielytra spectabilis.**—Will some one give me information on the culture of this plant?—G. W. [If for outdoor culture, plant it in deep, rich garden soil, and let it alone. If for pots, plant it out in spring and lift it in autumn, pot it, and place in greenhouse or window. The roots may be divided when too large.]

1757.—**Spiræa filipendula.**—I have some plants of this, which I keep in a steady bottom-heat. What treatment do they require when they begin to grow?—S. [Are you sure it is not Spiræa japonica? S. filipendula is a hardy border plant seldom used for forcing. In either case take the plants out of the bottom-heat, and place them on an airy shelf in the greenhouse.]

1758.—**Cucumbers in Frames.**—On February 27 I got some manure from a stable, and put it on my garden in a heap; and on 4th inst. I put it, ten barrow-loads into my frame, which is 5 ft. by 3 ft. On 6th inst. I put about 4 in. of earth on the top of the manure, and put in a Telegraph Cucumber plant. I then put on the lights. Yesterday and to-day the manure has steamed very much. I therefore opened the lights about ½ in. to allow it to escape; but what I am the most surprised at is that the bed has sunk down quite 1 ft., although I made it as firm as possible. Will it do the plant any harm if I take it out, and add a few more barrow-loads of manure on the bed?—G. E. A. N. [If the plant is still small you might remove the soil, and put in more manure, or better still, leaves; but if growing freely, add 1 in. of soil on the top, without disturbing it in any way. If the heat goes down put a lining of manure round the sides of the frame.]

1759.—**Moss Roses.**—Each Rose bought and planted in November last had about three shoots each, each shoot 3 ft. long. They are all breaking bud nearly to the top. How much should I shorten them when pruning?—C. H. [Let them remain as they are.]

1760.—**Improving Garden Soil.**—The mould in my garden is of a damp nature, and in some parts where it is hard it is covered with Moss. I have tried to grow flowers and vegetables, but they do not come to perfection. Can this mould be made any use of whatever? and which would it do for best, flower or vegetable garden?—G. H. MORTIMER, *Pimlico*. [The ground wants draining. Trench it 2 ft. or 3 ft. deep, and in the bottom of each trench bury a quantity of old bricks or stones; also apply some wood ashes to the soil to kill the Moss.]

1761.—**Cropping a London Garden.**—I have a garden in London on the clay; I do not know what to grow, and when I know what to grow I do not know how to grow it. I have two long beds, both manured, one facing the north and the other the south.—K. B. W. [If you read GARDENING from time to time you will get all the information you need; much has already been said on the subject.]

1762.—**Hyacinths after Flowering.**—My Hyacinths (in glasses) are nearly over; how shall I save them for next season?—NOVICE. [Plant them out in the garden; they are little or no use for next year.]

1763.—**Plants in Leaf-mould.**—Will Fuchsias and Geraniums do potted in leaf-mould?—I. A. G. [Yes, if you add half loam, or even common garden mould and some sand.]

1764.—**Helleborus niger**—When is the best time to plant this?—SUBSCRIBER. [Plant now or in April.]

1765.—**Tomatoes.**—What is the best soil for these?—S. [Turfy loam and a little leaf-mould.]

1766.—**Hyacinths in Pots.**—Will it be better to let my Hyacinths in pots remain in them for another season, or take them out and dry them off?—NOVICE. [Plant them out, and let them flower in the garden next year.]

1767.—**Planting Potatoes.**—When may I plant Magnum Bonum Potatoes? and what distance from set to set, and row from row? AMATEUR R. K. [Plant early next month. The rows may be 2½ ft. apart, and the sets 1½ ft. or wider if convenient.]

1768.—**Double Violets not Blooming.**—I have some nice plants, the buds of which wither instead of opening.—QUEENIE [Place them in a light airy window, and give them a little weak manure-water occasionally; water them only when they need it.]

1769.—**Planting Grape Vines.**—I have a Black Hamburgh Vine in a large pot; would it do planted inside of a greenhouse, as I have no place outside that would do, it is just breaking into leaf. What is the best soil? and should it be cut back? I can only plant it on top of the stages, as the flue and hot-water pipes go all round the house.—I. A. G. [If you can make room for a large square box inside the house the Vine would do in it, but it will not succeed well over the flues; cannot you make a place outside? Soil, loam and old mortar rubbish; plant at once; do not cut it.]

Procuring Clematis. — *S.* — These may be got at any good hardy plant nursery.

Double White Rocket.—*Ellesmere.*—At any good hardy plant nursery. See advertising columns.

Creeper for the Back of Greenhouse.—*J. A. G.*—A Gloire de Dijon, Maréchal Niel, or Devoniensis Rose will be as good as anything you can employ.

Sowing Sweet Peas.—*Tyrone.*—These may be sown till the end of April for autumn blooming.

Nasturtiums Eaten by Grubs.—*Tyrone.*—Mix lime and soot with the soil at once. The Nasturtiums will not be planted till May.

Stove in Greenhouse.—*W. L. E.*—The stove to heat a flue may be inside the house, but the fireplace must of course be outside.

Depth of Box for Japanese Maize.—*Tyrone.*—6 in. will do, but if deeper the better.

Ripening Pears in Cellars.—*Constant Reader.*—The cellar is too damp and the temperature too close and warm. Keep them as cool as possible, and dry.

QUERIES.

1770.—**Climbers for Walls.**—What will grow best on a wall with an east aspect? I have tried Virginian Creeper, which shrivels, and the leaves fall off before turning red.—BRAMBLE.

1771.—**Lawn Tennis Court.**—I am about laying down a lawn tennis court; the ground is somewhat on the incline. Can any practical reader give me any information how to proceed with the work, and the necessary materials required? At present the Grass is rank, and the subsoil (about 2 ft. down) is stiff loam or clay. Also what space is necessary for a full-sized and efficient tennis lawn?—R. K.

1772.—**Uses of Sulphate of Ammonia.**—Will some one tell me how to use sulphate of ammonia in a flower garden as an artificial manure or otherwise?—T. WILLIAMS.

1773.—**Plants for Screens.**—I have a room in my house with a window at each end. Outside one of them is a piece of ground where clothes are hung out to dry. This is disagreeable. Could any one suggest an inexpensive way of shutting out the view with flowers? It is a large window, not a bay.—OXONIAN.

1774.—**Growing Herbs.**—I wish to have a good supply of Mint, Sage, Thyme, and Parsley, all through the summer, beginning as early as possible. Will any one kindly give me a few hints?—LOCO.

1775.—**Gladioli for Exhibition.**—Would some reader who has grown Gladioli for exhibition tell me if Gladioli potted in 6-in. pots and plunged in the open border would give as good results as if planted in the ground? My reason for desiring to grow them in pots is that in case of boisterous weather I could remove them to the greenhouse a short time before the show, and so have the flower-spikes in good condition; but if this would be at the sacrifice of size in the flowers and spikes I would rather plant them in the open ground and provide a temporary protection during the blooming season.—FLORIBUNDUS.

1776.—**Hardy Coleus.**—I find in catalogues that Coleus Verschafelti is spoken off as the only hardy sort, and that not pefectly so. This is wrong, as there is a kind much more able to withstand the cold. It is a black-leaved kind, almost like the Perilla; yet far handsomer and more velvety. I lost my plants of it in winter. Can any one tell me the name of this Coleus, and where it can be obtained?—WITHYCOMBE.

1777.—**Cucumbers not Growing.**—For three years I have grown Cucumbers with tolerable success, and at the closing of last year I was requested to have these plants fruiting much earlier than heretofore; therefore I commenced operations at the beginning of the present year, and find that the plants in lieu of being earlier, will, if anything, be later. In January I put the seeds in; they came up all right, made their third leaf, and then remained at a standstill. The house is about 30 ft. by 12 ft., span roof, bed down each side, about 2 ft. wide and 1½ ft. deep. It is heated by means of a flue and two rows of 4-in. hot-water pipes, which run right round. From the time the seeds were put in, I have kept it as near 70° as possible—at times 75° with a moist temperature continually; but with all this, the plants will not grow. What must I do? The soil consists of one good-sized barrowful of Hops, which were used last year for heating outside frames; two of rotten manure, used last year for Mushrooms; and six of old rotten turf.—ONE IN A PROPER FIX.

1778.—**A Good Winter Vegetable.**—Seeing in a recent issue of GARDENING an article on the Leek from "A. H.," where he says they may be grown with 9 in. to 12 in. of clear white, I am desirous of gaining particulars as to rearing, transplanting, and growing Leeks; what manure is best for them, and how applied.—TYNESIDE.

1779.—**Culture of Statice Halfordi.**—Will some one kindly give me instructions as to the culture of this plant?—SUBSCRIBER.

1780.—**Culture of Polemonium confertum.**—Will any one tell me the soil and situation suitable for the successful culture of this hardy plant?—H. C.

1781.—**Black Kidney Potato.**—Can any reader inform me if there is another name for this Potato? In Mid-Kent it is called Nigger-boy. Also, where can sets of it be purchased?—R. BURNS.

1782.—**Black or Nigger-boy Radishes.**—Perhaps some one can tell me by what other name this Radish goes, and where the seed can be obtained?—R. BURNS.

1783.—**Removal of Fruit Trees, Shrubs, &c.**—As I am about to leave my house, I shall feel obliged if any reader will inform me if I can remove fruit trees, Rose trees, shrubs, &c., from the garden. I purchased them from the person from whom I took the house, and I hold the house upon a three years' agreement, which is silent upon the subject of removal of trees and shrubs.—A CONSTANT READER.

1784.—**Chrysanthemums for Show.**—When and where should I strike Chrysanthemum cuttings? What soil is most suitable? How can I grow them pyramid shape? Also, the last time for potting and stopping, so as to get them in for November show?—A. L.

1785.—**How to grow Arums.**—Would any one give me cultural directions for the following Arums: Dracunculus, æthiopica, italicum, crinitum, and maculatum marmoratum.—S.

1786.—**Soil for Hardy Lady's-slipper.**—Will any one tell me if the following Cypripediums will succeed well in pots of good turfy fibrous loam, the pots being half filled with drainage, viz.—C. Occidentale, arietinum, pubescens, spectabile?—L. S. B.

1787.—**Hyacinths not Growing.**—I have some Hyacinth bulbs which I planted in September in pots, and they have neither sent out roots or leaves; can any reader tell me the best thing to do with them?—GEORGE WHITE.

1788.—**Old-fashioned Flowers.**—My old-fashioned plants, which I am anxious to cultivate, will not thrive. I mean especially Primroses, Polyanthuses, Daisies, Pansies, and Alpine Cress. The roots come out of the ground, the leaves become smaller, and after a year or two the plants disappear. I have tried various aspects; I have planted and divided them at various seasons, or left them to themselves; but always with the same result. Will any one suggest a remedy?—E. R.

1789.—**Blue Flower for North Aspect.**—Would some one tell me the name of a small plant, the seeds of which I could get at any nurseryman's, which would grow in a north aspect in front of bushes? One with small blue flowers preferred.—H.

1790.—**Budding Plum Stocks.**—I have a quantity of Plum suckers, and I want to remove them to different parts of my garden; would it be best to graft or bud the suckers first, and then remove them at the fall of the year? Would Apples come to perfection grafted on Plum suckers?—F. B. B.

1791.—**Sowing Begonias.**—Having some Begonia seed of the tuberous-rooted varieties, I should be glad if some one would give me information as to what heat they require to raise them so as to bloom the same season?—C. C.

1792.—**Soot and Lime for Crops.**—Are these beneficial to Onions, Peas, and Wheat, and what quantity can I apply per square yard to each of the above named crops?—R. K.

THE HOUSEHOLD.

CABBAGE COOKERY.

OF all culinary vegetables the Cabbage tribe is the most ancient and the most extensively cultivated. Being extremely likely to run into varieties at the smallest provocation either from the soil or climate, the original wild Cabbage has given rise to the various white and red Cabbages, Savoys, Brussels Sprouts, Cauliflowers, Broccoli, Kale, the different Borecoles generally included under the popular name of "Greens," and even the Tree Cabbage of Jersey and the Turnip-rooted Cabbage, or Kohl Rabi as it is generally called. The usual method of cooking Cabbages in England is to cut them in four, soak for a couple of hours in cold salt water, and throw them into boiling water, to which a handful of salt and a pinch of carbonate of soda have been added. After about half-an-hour's boiling they are taken out and drained in a cullender or squeezed between two plates, and are then served up to table without any further preparation. A better way, however, of cooking Cabbage is to steam it or bake it. By steaming or baking we avoid the subsequent squeezing, which always spoils their appearance. Prepared in either of these ways, the Cabbage is at best an insipid vegetable, requiring the addition of many condiments to make it palatable. Those who know how to cook vegetables, however, have devised a large number of remedies for the constitutional tastelessness of this wholesome vegetable.

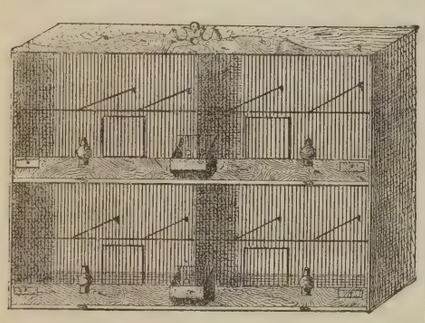
CABBAGE WITH BACON.—Trim and quarter one or more young Cabbages or Savoys. Soak in cold water for two hours. Throw into boiling water, boil for twenty mi-

nutes, and drain thoroughly, or if you have the appliances you may bake or steam instead. Mince a piece of bacon fat very finely, adding chopped Shallot, Onion, sweet Herbs, pepper and spice to taste; mix the mince well together and throw into a saucepan. When the bacon is melted lay your Cabbage in it, and add enough hob stock to half cover it. Simmer gently for twenty-minutes, and place the pieces of Cabbage on a dish. Thicken the liquor left behind with a little flour and pour over all.

STUFFED CABBAGE LEAVES TURKISH FASHION.—Blanch the long leaves of a White Cabbage. Cut out a number of pieces of the leaves of about 3 in. square, taking care to avoid the coarser ribs of the leaf. Make a mince of a pound of fillet of mutton, two handfuls blanched Rice, chopped Onion or Shallot, Parsley, fine Herbs, salt and pepper. In the centre of each piece of Cabbage leaf place a small heap of the mince and fold it like a small parcel, tying a piece of packetthread round it to keep it from opening. Arrange the little packets in rows in a stewpan, pressing them closely together. Cover them with broth and reduce to about one half. Place on a moderate fire for half-an hour and pile on a dish in the form of a pyramid. Pass the liquor in the stewpan through a sieve, boil up, thicken with beaten-up egg, and flavour with lemon juice to taste.

HOME PETS.

Breeding Cage. — The accompanying sketch is a four compartment breeding cage, which for saving time in feeding, &c., is invaluable. The best wood is American Pine; the front parts should be Mahogany. The doors are in front, being made of wire. One seed-box answers for two compartments, as may be seen by glancing at the sketch. A water-bottle is provided for each division; also egg tray in each corner. One sand tray is sufficient for two compartments, as it runs right along. This four-division cage can be made very cheaply by any one having a little ingenuity and mechanical taste, and can be ornamented at will. A good



Breeding Cage for Canaries.

size would be 3 ft. square and say 1 ft. deep. The wire should be what is called No. 17, and for the cross pieces No. 13. The tin binding wire for securing them together is 10d. per lb., Nos. 17 and 13 about 8d. per lb. To pierce the holes in the wood ready to receive the wires it is a good plan to file down a bradawl to the exact size and length the wire is to go into the wood, as in this case the wires can all be cut the same length, and no difficulty will arise in fixing them.—A.D'A.

Breeding Canaries.—I have bred canaries for several years and only lost two young birds during the time. The method I pursue is this: Give the parent birds chopped egg, bread crumbs, and Maw seed mixed from the time that they are put in the breeding cage; also plenty of green stuff and a bath daily till the hen sits. I always leave the eggs in the nest, and do not allow them to be frequently looked at. I believe failure of so many broods arises from the constant peeping of friends. The eight young ones I raised last year were hatched and reared in the sitting-room, there were plenty of light and warmth, but the cage was never disturbed, except for cleaning and supplying the birds with food.—S. S.

Food for Bullfinches.—Is Millet a wholesome seed to give bullfinches and canaries? I wish to vary their usual diet of rape and canary seed.—H. R., *Christchurch*.

Birds for Aviary.—What birds (British and foreign) would be best for a small aviary, 2 ft. by 3 ft. and 4 ft. high, in a conservatory?—EVAN DHU.

BEES.

Plants for Bees and starting Bee-keeping.—"W. B." is wrongly informed that "'Bees never gather honey near their own hives.' Mignonette is good, so is the common blue Veronica, and many other plants; but his bees can gather but a very small proportion of their honey from his own garden; they will range over a radius of two miles from the hives, gathering from all flowers suitable. "W. B." says he has been offered a "stock" or a "swarm" of bees in the spring. If he gets the former, let him have it now by all means, feed it; and he may have a swarm also by the end of May if the weather is propitious. If a swarm, he must, of course, wait until his friend has one to send him. I should strongly advise him to use bar-frame hives; and of these the Woodbury size is the best, but not the original Woodbury construction. Let him have his frames with wide shoulders, fitting one against the other without notches or tacks. The aspect is immaterial, so long as the entrances are not exposed to cold north-east winds in winter, and the hives are not in too hot a position in summer. They must not be moved about, but where placed must stand. A stock to travel 100 miles should (I presume it is in a straw skep) be covered with cheese-cloth tied firmly over the open mouth, and reversed, *i.e.*, the crown downwards, so that the combs rest on the crown instead of hanging from it, as in the ordinary position. This is to avoid risk of breaking down; a rope handle should be put across for railway porters to lift by, and distinctly labelled "This side up." A swarm may be sent in any box with plenty of ventilation, and turned into its hive on arrival. If in a good honey country, and in a good year, 40 lbs., or even as much as 100 lbs., of honey may be obtained from a stock; but 20 lbs. to 30 lbs. is a fair quantity. By the bar-frame system, and using an extracter, 100 lbs. may be obtained, more likely than 40 lbs. from a skep. Sugar and water (not beer) boiled to a syrup is obviously cheaper for bees to live upon during the winter than honey, and more healthy for them.—APIS.

POULTRY.

Pure-bred Fowls.—Are pure-bred birds more profitable than cross-bred ones? Yes, if they be the right birds in the right place—that is to say, of a breed suited to the locality and conditions under which they are kept. No one should attempt to keep a delicate kind on a cold, damp soil or exposed situation, or a range-loving kind, such as game, in a small back yard. And yet high prices are paid for pens of pure-bred fowls every day by persons ignorant of their requirements; failure is the result, and a return to the old stamp of mongrel, which, in nine cases out of ten, is an indifferent layer, and eats its head off six months during the year. Again, one can never feel the amount of interest in a lot of cross-bred birds, perhaps not two of which are alike, as in a nice pen of some pure breed, in which there is something to study and admire. It is a well known fact that cross-bred birds eat much more than pure-bred ones. Then as to laying qualities, what mongrel hen was ever known to successfully compete with the Hamburgh or Leghorn in point of number of eggs? Perhaps the most economical method to get together a pen of pure-bred birds is to purchase a sitting of eggs from some good breeder, of which numbers are now being advertised at from 5s. to 10s. a dozen, and to carefully set them under a good steady hen, and, almost needless to add, to look well after the chickens until matured.—ANDALUSIAN.

Food for Fowls.—Can anyone tell me whether Hominy is as good as Oatmeal for feeding fowls?—HEN-WIFE.

How to Make an Incubator.—How can an amateur make a cheap and effective small machine for artificial hatching chickens?—A NORWICH SUBSCRIBER.

Brahma Fowls.—These should have low perches about 1 ft. from the ground, and they should be made large and square to suit their large feet.—M. J. S.

White Brahma Fowls.—Now is the proper time to set eggs for obtaining pullets to lay in winter. Chickens should only be hatched during March, April, or beginning of May to be profitable.

Chickens Losing the Use of their Legs.—I had some light Brahma Dorking chickens which were hatched on January 15th 1880, and for the last fortnight they have lost the use of their legs, yet they eat well. Can any reader kindly inform me how to cure them?—G. N. B.

Eggs for Hatching.—Eggs, if placed in holes on their broad ends, will keep a month for setting; but if stored on the small end not more than half that time with certainty. Of course the fresher eggs are the better for setting, and the stronger the chicks.—W. B.

Tortoise.—What is the lowest temperature to which tortoises can be exposed without injury? On what will they feed if left to themselves in a warm kitchen garden? Or what should I give them? Do they require water? I should be much obliged for any information. I have also a pair of small American water tortoises; should I give them a little raw fish?—H. R., *Christchurch*.

GARDENING
ILLUSTRATED.

VOL. II.—No. 55. *SATURDAY, MARCH* 27, 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

VARIEGATED TREES.

Of all variegated trees, suited alike for large or small gardens, the variegated Maple (Acer Negundo albo-variegatus), which we now figure, is perhaps the most striking and ornamental in appearance. It may be employed in various ways. Grown in bush form on its own roots, or grafted close to the ground on a stock of the plain-leaved variety, it forms handsome bushy specimens, which may be used in combinations of all kinds. It may be used to form the outside margin of groups which have been already planted in the ordinary way with variegated or plain-leaved trees or shrubs. Grafted as a half-standard at various heights, it can be employed in groups planted with regularity, and consisting of trees or shrubs arranged in an order graduated according to the stature of each. If a rather tall half-standard is required, it should be grafted on a stock of Acer californicum. A group formed exclusively of this variegated Maple, grafted as tall standards and half-standards, with purple-leaved or deep green-leaved shrubs planted among them as underwood, presents a most splendid effect; but this can only be done when the adjoining grounds are extensive. In small gardens a well-grown single specimen, either trained as a standard or bush, will give much better effect than rows or groups of it. Indeed, the greatest mistake we have seen made with this handsome tree has been overplanting. A large shapely head of it standing boldly out from among glossy green, low-growing shrubs has a much more telling effect than long banks and borders planted solely with this one kind of tree. This Acer will grow in almost any kind of soil or situation, but its variegation is brought out to the best advantage when it is planted in deep sandy and not too rich a soil, and in a warm sheltered position, where its leafage is not torn by the wind. The Japanese Maples which have been introduced to our gardens during the last few years are admirable subjects for small gardens, where a warm soil, and not too cold a climate, exists. They have beautiful copper-coloured, Palm-shaped leaves, they are elegant in habit, and though rather expensive they well repay their cost. They are also excellent subjects grown in large pots for unheated conservatories or corridors. They are extensively grown in Messrs. Veitch's nursery, Coomle Wood, Kingston-on-Thames. The purple-leaved Peach is also a handsome tree of recent introduction. It is perfectly hardy, grows freely in good soil, and its rich bronze or purple foliage would form a striking contrast to that of the Acer negundo above alluded to. Some of the variegated Privets, too, when grown in tree form are well suited to small gardens; and if a golden-leaved tree is needed, the golden-leaved Elder surpasses all others, the variegated Holly excepted. It is a plant of free growth, and only requires to be cut down nearly to the ground yearly to form a bush of large, bright, golden foliage. In some of the London parks it is used in the front of shrubberies, and for forming a background to beds of summer bedding plants. There is also a silver-leaved variety of the Elder, but it is not nearly so effective as the golden-leaved kind. The Golden Yew also makes a fine lawn tree. It should be grafted on stocks of the common kind, and may be grown either in the form of standards, pyramids, or bushes. We have seen it grafted on the top of plants left uncut in hedges, and when large heads

THE SILVER-LEAVED MAPLE.
(Acer Negundo variegatum).

are formed a fine effect is gained. There is a copper-coloured-leaved Filbert well worth growing in the rougher parts of the garden; and with the copper-leaved Beeches of course every one is acquainted. In conclusion we may remark, with regard to variegated trees, that a preponderance of any one kind should be avoided, and that in all cases one well-grown specimen of each kind will give better results than a crowded mass of trees and shrubs of any kind.

VEGETABLES.

NOTES ON SOWING SEEDS.

Sow only seeds of good quality, both as regards germinating power and pure stocks. A favourable seed time can generally be had by watching and waiting, and promptly taking advantage of it when it arrives; it is better to wait a few days than to sow when the ground is in an unfit condition to receive the seed. But with land difficult to work in a backward season a crop may often be successfully got in with the aid of a few light boards laid across the bed; this, in some cases, may perhaps involve a little more labour, but it ensures success. The same means may be usefully employed in transplanting in wet seasons, as nothing makes land that is naturally adhesive so unfit for plants as treading on it when its surface is wet. All seeds are best sown in drills, at varying distances, according to each particular kind, but in all cases room should be allowed to use the hoe freely. Both thick and very thin sowing are, in certain cases, evils to be avoided; but the character of the land should be considered in deciding what quantity of seed to sow. On light, warm land, where every seed will grow, fewer seeds should be sown than on damp, heavy land, and where, perhaps, in a cold, unfavourable season, slugs and other insect enemies may be troublesome. Besides, no matter how good the seeds may be, some will produce better and stronger plants than others, and there should always be sufficient plants on the ground to allow of a choice being made, so that the crop, when finally thinned, may consist of selected plants only.

The depth at which seeds should be buried should bear some proportion to the size of the seed; but the character of the soil in which they are laid is even of more importance. In warm, dry soils seeds may be safely and advantageously placed deeper than where the soil is of a heavier nature. Drills for what are termed small seeds need not in any case be more than ½ in. deep, and less will suffice on heavy soils. In the latter case, unless the soil be in a mellow condition, cover with a prepared compost, of which burnt earth, or decayed vegetable matter from the waste-heap, form the chief part. When this plan is adopted, no matter what the soil or the season, the seeds will germinate regularly and well. Larger seeds, such as Peas and Beans, may be covered 2 in. for early crops, while later sowings may be put in a little deeper. The same remark applies to later sowings of small seeds, such as those of Turnips, as it often happens that in dry weather, by burying them just a little deeper, the seeds can be laid in moist soil, and will, in consequence, germinate more speedily, and when seeds lie long in the land the crop cannot be so even or regular. In certain cases the germination of seeds may be hastened by mixing them with some damp substance, such as sand, or by soaking them in water for twenty-four hours or so before sowing; but the most natural way is usually the best, and artificial plans should only be adopted where, from some unavoidable cause, the sowing of the crop has been delayed.

All seeds should be sown on moderately firm land; for some plants, such as Onions, this is indispensable, and it is especially necessary if the land be of such a nature as to not readily consolidate or settle down, and there is a vast difference in different gardens in this respect. Treading is the means commonly adopted to secure solidity, but where land is very light the iron roller may be drawn over it twice in contrary directions. If the surface be not sufficiently dry to bear the roller, or even the feet, at the time of sowing, delay the sowing till the surface is in a suitable condition. This need not, however, interefere with the sowing of the seeds, as the final treading or rolling may be given a week or ten days after the seeds have been sown, and it will be better to do it then than not at all.

Nothing is better than lime dustings to preserve young plants from slugs, and early in the morning or late in the evening is the best time to apply them. Stirring the surface among the young crops the moment they appear, freely and often, will also help to keep the slugs in check, as they cannot travel well over a rough, uneven surface, and the stirring will also encourage and stimulate the young plants to grow up out of their reach. Scattering dry ashes over any crop to which slugs are partial is likewise a good preventive, as their soft, slimy bodies cannot get over the sharp, jagged edges of the small particles of cinder with which sifted ashes abound. Where mice or birds are numerous and troublesome, the seeds should be thinly coated with red lead just previous to sowing, in order to make them distasteful. This is easily done: first damp the quantity of seeds to be sown with water or oil; then scatter a little dry lead over them, and stir and mix altogether. It must not be forgotten by persons unaccustomed to the use of such substances that red lead is poisonous. Paraffin oil may also be used for soaking seeds in to preserve them from vermin; but as commonly sold in the shops it greatly varies in strength, and should be used first experimentally till its effect has been fully proved.

Celeriac or Turnip-rooted Celery.—Of vegetables used in foreign countries, large quantities are not worth growing in England;

Turnip-rooted Celery (Celeriac).

but the Celeriac is an exception. It is by no means difficult to grow; and it is one of the most useful of winter vegetables, coming into use, as it does, when the kitchen garden is almost bare. On the Continent it is met with on every table, and is considered a welcome delicacy. A deep, well-prepared, rich soil is necessary to grow it well. It should be sown in February or March on a hotbed, or in pans under glass; the seed will come up in about sixteen days. Thin out, transplant in another genial bed as soon as the seedlings will bear handling, and plant them in the open ground in May, 14 in. apart, in rows 16 in. asunder. Frequent hoeings and a thick mulching are of great benefit to the plants; and during summer water must be abundantly supplied. The roots of the Celeriac are ready for use by the beginning of October, and they may be kept in the open ground until the following April, if protection be given them, consisting of mats, straw, or any other kind; otherwise they must be removed to a cold cellar before severe weather sets in, or they may be put in a bed close together after part of the leaves has been cut off. Thus situated, they will be easily secured from frost. In February, however, they must be again removed, in order to check growth, which would destroy their quality. Treated in this way, Celeriac will be most serviceable during the winter, and will afford excellent dishes. It never requires earthing up—an advantage which it has over Celery. As regards its use, cut off the leaves, remove all irregular knobs, give the root a hard brushing in clean water, and it will be ready for the cook. In a raw state, cut into thin slices, it forms a good addition to winter salads. Cut in pieces ½ in. thick, and, when boiled, fried with butter, and served with sauce, is the general way in which it is put on French tables. Boiled as above and made into salad, with salt, pepper, oil, and vinegar, like Potatoes, is the chief way in which it is used in Germany.—D. G.

Vegetables for a Clay Subsoil.—Situated as we are, under clouds of smoke and chemical vapours, with a subsoil of clay yards deep, it requires both time and attention to select the sorts of vegetables most suitable for cropping such a soil, as many of the better kinds do not yield even one-third of a crop. Allow me, therefore, to enumerate such varieties as may be relied upon to produce, with proper attention, satisfactory results, commencing with Broccoli, which depend so much on the character of the winter and the method of cultivation. Frogmore, Knight's Protecting, Dwarf Russian, and Brimstone we find to stand well. Brimstone is, however, most to be trusted. Amongst Cauliflowers, Autumn Giant is quite at home, and also Walcheren, for August sowing. Negro, or dark or pale Dun Kidney Beans answer well. Amongst Lettuces, Tom Thumb and All the Year Round have proved to be very good, but all the Cos varieties under ordinary cultivation are poor. Peas, being most important, require extra attention, for if the seed get starved before it comes through the soil a poor crop may be expected. A trench, a spade deep and about 1 ft. wide, should be taken out, and filled up with leaves or littery manure, and covered over with soil; on this sow the Peas, which will thus be kept dry and warm. Little Gem, sown thinly, three rows on a 4 ft. bed, with a few branches between the rows, produces good crops, and comes in early. In fact, it is a useful little Pea and well-flavoured, and as it only grows from 12 in. to 18 in. in height, it may be sown in any snug corner. Alpha and Advancer may be both sown on the same day, as the latter is eight to ten days later than the former; both are good in flavour, and abundant bearers. For the general crop, Champion of England, Yorkshire Hero, and Prince of Wales should be selected; and for late crops, Ne Plus Ultra and Omega, combining, as they do, quantity and quality. Omega only grows about 3 ft. in height, and is very desirable where Pea stakes are scarce.—J. S.

Shallots from Seed.—I do not think it is generally known that Shallots will grow much finer from seed than from the parent root. The seed should be sown early in March in ground prepared as for Onions, namely—trench the ground two spits deep with a quantity of manure, and then tread the surface as hard as you can. Sow the seed in drills. This is the common, not the true, Shallot. The common Shallot is very nearly allied to the Onion, and seeds freely. The true one does not.—W. S.

Beck's Green Gem Bean.—I have received so many letters from readers of GARDENING ILLUSTRATED anxious to procure this excellent dwarf Broad Bean, that I fear it is not in many of the country nurserymen's seed lists. It is by no means a new or rare vegetable, as I have grown it for years from seeds procured from Messrs. Veitch, of Chelsea, and Messrs. Osborn, of Fulham. It is a really genuine acquisition for amateurs with small gardens, as it produces an immense crop of delicious small Beans, greatly preferred for table to the large Broad Beans in general cultivation. There are plenty of willing purchasers for such things who have no use for startling novelties.—J. GROOM, *Linton*.

The Hop as a Vegetable.—Although so much grown for its well-known use, and often seen as a climber in small gardens, the Hop is little grown in England as a vegetable. In Belgium its use as a vegetable is almost universal. The young shoots are cut as soon as they are 2 in. or 3 in. above the ground, and boiled in salt and water; they are then dried and sprinkled with the juice of a Lemon to keep them white. Before serving, put them again over the fire for a few minutes, with salt and plenty of butter, then add eggs mixed with milk, when they may be eaten like Asparagus, to which they are not inferior. Managed in this way, it makes a most delicate and refined dish. The young shoots of Hops are generally cut twice for the sake of strengthening the plants; therefore it would not be advisable to grow Hops

for their shoots to be used as a vegetable only—when they could be gathered in Hop-fields, in gardens, and even in a wild state, all of which are equally good. If this were well known, many of the inhabitants of Kent would add a wholesome dish to their tables, and might even make money by sending the shoots to market. —D.

Crisp Celery.—In order to grow crisp Celery, the manure put into the trenches should be as rich and rotten as possible. If there be any straw or dryness in the manure, the Celery is sure to be pithy and not crisp. Another great point is never to let the plants suffer from want of water or liquid manure, both when first planted out and during dry, warm summers; some varieties of the dwarfer kinds of Celery are more nutty and crisp than the larger-growing sorts. Among whites, Sandringham and Turner's Incomparable belong to this class; and amongst reds Sulham Prize Pink and Major Clarke's Red.

Garlic.—Garlic, though flourishing best in a dry, fertile soil and warm situation, will do almost anywhere. Plant the cloves, *i.e.*, the separated portions of the "bulbs," in shallow drills about 1 ft. asunder, and 6 in. apart in the row, covering them with soil to the depth of an inch or two. Or plant old bulbs 1 ft. apart each way, and never deep, as wet is apt to get down among the cloves, causing canker and mildew. Merely stretch a line or measure; take the bulbs by the neck, and press them half, or say two-thirds, into the soil. Then drop a pinch of fine sifted cinder ashes over them, to prevent worms from drawing them out of the ground. February or March are about the best seasons to plant them. A small quantity may be planted in autumn, if it is desired to have a stock early the following season. From this autumnal, or, to speak more precisely, October planting, bulbs may be taken up for use early in the succeeding summer. Any time after the leaves turn yellow the crop may be taken up and dried, hanging it up in bunches by the stalks in any airy room. It requires no culture whatever, excepting to be kept free from weeds—if it be necessary to mention in connection with any one small crop what is a first necessity with all.—J. B.

Autumn Broccoli.—Two years ago, having found a small planting of Self-protecting Autumn Broccoli to come into use just at the desired season—viz., in autumn, after Cauliflowers were over—we last year grew it largely with the most satisfactory results, as we had an abundant supply until the early spring varieties were fit for use. We sowed the seeds of it the first week in April, and as soon as the plants were large enough to handle, they were pricked out into nursery beds until the first crop of Peas was cleared off in the end of June, when drills were drawn, and the young Broccoli plants put out 2½ ft. apart, with a crowbar, on solid land. One good soaking of water, and an occasional surface-hoeing, were all the attention they received until November, when they presented as dwarf and even a surface as I ever saw in a plantation of Broccoli, every plant being short and sturdy in the stem, with a fine head of leaves that curled over and enveloped the heads so completely as to defy any moderate frost. As a precaution, however, against any sudden visitation of severe weather, we laid them slightly sloping to the north, and packed dry Fern and litter securely among them, reserving a supply for effectually protecting overhead should frost become intense, as I find Broccoli or Cauliflowers are much better in quality when protected in this way than when lifted and placed in close pits or cellars.—J.

Leeks for Use in Spring.—At this season of the year, when old Onions are getting past their best, and autumn-sown ones are scarcely fit for use, Leeks become especially valuable, and by many are preferred to Onions on account of their mild flavour. The seed should be sown at once, and as soon as the young plants are large enough, they should be transplanted in shallow trenches, like Celery, two or three rows abreast, so as to allow of soil being worked amongst them. If planted on level ground deep holes should be made, and the plants dropped in, with just sufficient soil to cover them, afterwards earthing them up as they grow. I find the London Flag and Ayton Castle excellent kinds for general purposes.—J.

FRUIT.

MELON CULTURE IN COOL PITS OR FRAMES.

Everybody who has a pit or two for bringing on bedding plants has the means within his reach of securing a supply of good-flavoured Melons at least in August, September, and October. In Melon culture, without much artificial heat, one of the chief elements of success lies in the selection of suitable kinds for the purpose; and one of the best varieties I have hitherto tried under cool treatment is Victory of Bath. It is a green-fleshed kind, possessing a hardy, vigorous constitution, sets freely, is of good flavour, and, I may add, is first-class in every respect. Amongst scarlet-fleshed kinds we have hitherto found Scarlet Gem most useful, the only objection to it being its size—it is rather too small.

The end of March is early enough to make the first sowing, to have strong plants to turn out the first or second week in May; and a pit may generally be spared by that time, as many of the hardier kinds of bedding plants will then be hardening off in the open air. Another sowing may be made about the middle of April, and a third about the end of the month will furnish a succession of plants for planting all the pits as they become vacant. When the pit or frame is clear of bedding plants, clear it out and have it thoroughly lime-washed, and filled to within a foot of the glass with any fermenting materials that may be at hand. Stable manure is the best, treading it well down; the object is to get a nice root warmth to start the plants till we have warm summer weather. When the heat has subsided a little—and as the bulk is not great it is not likely to be violent—pack into the centre of each light about three barrowloads of good strong turfy loam, levelling a little of it down to the back and front, in order to keep down any noxious gases that may arise from the fermenting material. In two or three days, when the soil is nicely warm, the plants may be put out, and unless the lights or sashes are very large, one plant in the centre of each light will be sufficient. There is never anything gained by crowding, but rather the reverse. The pits must be matted up at night, unless the nights are quite warm in July. The after management is very simple, the great secret of success being timely attention to their wants, which may be shortly summed up thus:—

In planting take care that there is room for the full development of the foliage, without coming in contact with the glass, and then, if the ventilation is attended to, there will be no fear of scorching. Attend frequently to the stopping and pegging out of the shoots; to allow them to grow into a thicket, and then to be compelled to use the knife to amputate strong growths, is bad. Earth them up as soon as they have fairly begun to run, pressing down the soil rather firmly. A firm soil checks grossness of growth and promotes fruitfulness. Sprinkle them about half-past three o'clock in the afternoons of fine days with water that has stood in the sun all day, shutting up at the same time. When a sufficient number of fruit for a crop is set (and with summer Melons there is not much difficulty about this matter, for bees and insects generally perform that part of the work after May) cut off all that are not required, and mulch the beds over with short manure. During the time the fruit is swelling, Melons take a good deal of nourishment, and the mulching will be a great support to them.

Red spider is the greatest enemy with which Melons have to contend in the way of insect pests, but by taking care that the pits are cleansed and whitewashed annually, sprinkling and shutting up early on fine days, giving air early in the morning, to be followed by a free circulation, but no shading, and moderate root watering, with water from which the chill has been taken—if all these things are attended to there will not be much trouble with regard to red spider. Whenever, however, it has by any neglect or oversight effected a lodgment, the best remedy I have ever found for it is, after the morning ventilation has been given, on a warm sunny day, to close the pit, having previously thoroughly saturated its atmosphere with clean soft water, by syringing the walls and every available part of the interior, so as to fill it with a dense vapour, and to keep it closed several hours, if necessary repeating the syringing and slightly shading if the day is very hot. The theory upon which this cure depends is this: red spider thrives amazingly in a high dry atmosphere, but moisture in any state it abhors; and a close, warm, moist atmosphere is death to it. I have always found this remedy efficient, if taken in time, in the case of both Melons and Cucumber. Of course when the leaves are destroyed by it nothing will resuscitate them. The two most fertile sources of red spider on any plant are extreme dryness either at the root or in the surrounding atmosphere, and deficient ventilation. As the fruit approaches maturity, less moisture must be given, especially at the roots; although if the weather is very bright, a light sprinkling or dewing over with a fine rose or a syringe in the afternoon will help to keep the foliage clean and healthy, for without healthy foliage finely-flavoured fruit cannot be obtained. E. H.

Hedge of Grape Vines on the Top of a Wall.

Growing Fruit or Creepers on the Tops of Walls.—The annexed sketch shows an easy and ornamental way of adding to the height of walls when such a course is necessary. A simple wire railing is placed on the top of the wall, and along it may be trained any kind of flowering climbers, such as Clematis, Tea Roses, &c.; or in very warm, sunny places Grape Vines would answer admirably.

Strawberries that Resist Wet.—Those that I have found to stand wet weather best are Keen's Seedling, Dr. Hogg (a good variety of British Queen), Admiral Dundas, Elton (a late variety), and the old Eliza. These, I think, are superior to all the new kinds.—Rambler.

How to make Vines Break their Lower Buds.—Early forced Vines, especially pot Vines, are generally disposed to break their top buds, or the latest formed ones, first. A sharp bend, by tightening the tissues and arresting the ascent of the sap, will cause the lower buds to break—at least those immediately below the bend; but twisting the cane regularly its whole length checks the rush of sap through the tissues more effectually, and causes all the buds to break. Another good plan is to keep the bottom part of the cane near the pipes and the top away from them, and comparatively cool. I have often adopted this plan with long Vine rods of one year's growth, and have always found it to be successful.—J.

Canterbury Bells.—Now is the best time to sow seed of Campanula medium and its varieties if it be desired to secure large, massive plants that will produce several spikes of flowers, and display the beauties of one of our finest hardy border plants to the best advantage. The seed is small, and may, if plentiful, be sown in

a warm spot in the open ground, but it is much safer to sow it in shallow pans or boxes placed in a frame or on a shelf in the greenhouse, as in the latter case all the seed will probably germinate and an abundance of plants be secured. When these are large enough to handle conveniently, prick them out into some shady spot, and keep them watered until the plants are well rooted. From that time they may safely be left to take care of themselves until September, when they should be transplanted into their permanent places in the flower borders, and so treated will not only get well established before the winter arrives, but will also develop their blooming crowns for the next year. This constitutes nearly all that it is needful to say as to the raising of a seedling stock of these Campanulas, better known as Canterbury Bells. They may be classed into three sections—single flowers, as seen in the old-fashioned single Bells; doubles, as found in the stout massive flowers in which two, three, and even four bells seem to be compressed into the outer one; and duplex flowers, as seen in the calycanthema forms, in which one bell grows in the other, and the combined two resemble a cup standing in a saucer. The single varieties, as of old, are still to be had, but no one would care to be dependent upon these only who have once seen the beautiful products of a fine modern double and semi-double strain, and which will also produce some single flowers. Whilst the old single strains comprised only white and blue colours, the modern strains include nearly a score of hues, inclusive of white, lavender, mauve, several shades of purple, pink, rose, salmon, and also blue. The duplex strains have hitherto been chiefly confined to white and blue, but other colours are now being introduced. It is a curious fact in relation to this section that whilst the seed of the white form is of a pale hue and the seed of the blue form is of a dark tint, the seed of the double and semi-double forms of all colours is the same, viz., a glossy brown. The habit of the latter section is compact and good, the plants when in bloom ranging from 18 in. to 24 in. in height, forming perfect pyramids of flowers. From frequent experience I have found that these may be lifted and placed in pots even when in full bloom without injury, and as they invariable flower from the middle of June to the middle of July, according to place and season, it would be possible, in the shape of a large group of these in pots, to introduce to some of the midsummer shows a very novel and interesting feature. If so required, or if to be used for corridor, house, or conservatory decoration, it would be best to lift the plants and pot them into 6-in. pots early in May; this would enable them to get well established before the blooming period. The calycanthema section usually exhibits both a taller and a looser growth, and should be planted in borders behind the double and single kinds.—A.

The Foxglove.—The wild Foxglove of our hedgerows is a favourite and pleasing summer flower growing here and there singly or in clumps by the sides of the lanes, or in the woods; but its decorative qualities are best seen when growing in large masses. Wild Foxgloves seldom differ in colour; rarely is one seen that is not of the common red kind, and if one that is really distinct were found it probably would be torn from its roots and borne away in triumph. Garden varieties are not so circumscribed in this respect. In these the colours vary much, and include pure white, cream, rose, red, deep red, and other shades. The great charm, however, of the garden varieties lies in pretty throat markings, consisting of spots and blotchings of deep purple and maroon, and these, when seen in large flowers, make them resemble those of a Gloxinia; hence the name gloxinioides, applied to some finely-spotted kinds. The garden plants are more robust, the stems stouter, and the flowers much larger than those of the wild kind; and, altogether, they make at the present time truly grand border flowers. The seed being small, it is best sown in pans or boxes under glass early in May, and when the young plants are well up they should be placed out of doors to get thoroughly hardened before finally planting out. Where planted in shrubbery borders it is well to make clumps of three plants, as they produce a finer effect than when set singly. Not unfrequently the Foxglove blooms two years in succession; but in all cases it is well to sow a little seed annually.—A. D.

A Blue-flowered Garden Plant (Commelina cœlestis).—I would like to draw the attention of those who love a mixed border to the above plant, which deserves to be well known. The colour of its flowers are of that lovely and intense blue so rare in Nature, and its leaves, somewhat resembling the Begonia in shape, are very pretty. If tubers be planted at once in the open, they will commence to flower in June, and if prevented seeding by being kept well picked, will continue in bloom the whole summer. It appears to thrive in almost any soil, and in the winter simply wants taking up and storing away as a Dahlia. When I add that this plant can be purchased for the modest sum of fourpence, the wonder is increased that it is not everywhere seen in the gardens of all those lovers of Nature who get beyond the stereotyped Calceolaria and Geranium. It is called the Blue Spiderwort.—LEWIS W.

Calceolarias in Trenches.—The readiest way of protecting these from late spring frosts is to transplant them into trenches, similar to those used for late Celery. We have just transferred our stock with good balls of earth into trenches 3 ft. wide and 1 ft. deep; a few cross bearers are then laid over the trench, and at night or during hail or snow storms they are covered with long canvas screens; or evergreen branches might be substituted until the beds are cleared for their reception.—J. G.

Tyerman's Groundsel (Senecio pulcher).—This is a first-rate border plant, growing to a

Tyerman's Groundsel (Senecio pulcher), showing growth of plant.

height of 2½ ft., and bearing large purple Daisy-shaped blossoms from early in summer till late in autumn. It grows well in rich sandy soil, and it can be increased by seed and division of the roots. It is obtainable at any good hardy plant nursery.

Tuberous-rooted Begonias.—These beautiful, free-blooming, and easily cultivated flowers are rapidly becoming great favourites; and the more widely they become known, the more they will commend themselves to notice, as undoubtedly they are the best value that can be obtained—in the first instance during the months of June, July, August, and September as ornaments of the summer bedding garden; and, secondly, as soon as there is any danger of frost at night, as ornaments of the conservatory for another month or six weeks by lifting them into pots from the beds, which can be done without the slightest check, as they invariably lift with capital balls and masses of fibrous roots closely and compactly surrounding the tuber. They afford five months of continuous and uninterrmittent bloom, which is more than any other plant with which we are acquainted will do. All they require to make them thrive and grow luxuriantly and quickly into large, free-branching tufts is a light, rich soil, and copious waterings while making their growth if the summer be at all hot and dry. The beds should also not be planted too thickly, as if the tubers be at all strong and of good size they make such vigorous and abundant growth, that if put too close to one another the plants will soon get crowded; but when this inadvertently happens, every second one may with perfect safety be taken up even in the middle of summer and removed to another bed, where, after a good watering, it will next day appear as if it had never been transplanted at all, and the room afforded by its removal will be most welcome and serviceable to those left in the bed, allowing them fully to develop themselves, by means of which growth they will soon cover and fill up the gaps made by the removals in question. Begonias require a sheltered situation, fully exposed to the sun, as they object to exposure to high winds, which are apt to break off the soft succulent stems at their junction with the tuber. No amount of heavy rains does them the slightest injury; the blooms are not knocked off by it, and though the heads droop somewhat and bend under it, they rise again absolutely uninjured as soon as the sun shines out after the shower. Those who wish to increase their stock of these lovely plants should begin in good time to take off their cuttings, just as they would those of a zonal Pelargonium, about the middle of July, and these cuttings will root freely in silver-sand and water in from a fortnight to three weeks, and before the end of the season make good-sized tubers, which often give a little bloom towards the end of autumn, and flower abundantly in the open ground the following year. Indeed, young tubers in about their second year often yield individually finer blooms than older and larger ones, which as soon as they commence to start and show the eyes from whence the shoots spring, may be cut up just like a Potato.—W. E. G.

Raby Castle Wallflower.—This is the best habited of all the Wallflowers, and, to my mind, the best in colour, notwithstanding the prejudice (at least for market purposes) in favour of the dark varieties. It is nearly equal in colour to Cheiranthus Marshalli, and a few plants of it in early spring brighten up a place wonderfully. But I am desirous of pointing out its utility as a pot or decorative plant. Sown now (March or April), and when strong enough planted out to nurse in poor stiff soil, stout dwarf plants about 9 in. or 1 ft. high will be the result. These lifted late in autumn, wintered in a cold pit, and introduced early in spring to the conservatory or window, will yield a scent and give a mass of flower that will be very acceptable so early in the season. Everybody loves the scent of a Wallflower.—T. W.

How to Raise Anemones from Seed.—The following method will enable any one to raise Anemones with complete success, provided the soil be suitable—namely, a moist loam. The seed may be sown at once. As to the seed-bed it need not be large. Choose the sunniest part of the garden. Dig and rake till the surface is very fine, tread it down, and give it a good watering. Wait until the surface is dry enough to scratch with a fine rake; sow broadcast, covering the seed about the thickness of a shilling; beat flat with a spade, and give a light sprinkling of water. Now comes the most important point in my method. Never let a ray of sunshine reach the bed; cover it with newspapers, spreading a few Pea sticks or something to retain the covering in its place. Keep the surface of the bed always moist. In about twenty days the young plants will begin to appear; when all seem up, remove the covering, and no further care will be needed except watering. This must be strictly attended to, for if the bed becomes once thoroughly dry, the plants are apt, after forming small bulbs about the size of Peas, to stop growing, the foliage to die, and the bulbs to lie dormant for months; but if kept well watered through the summer they will go on growing all through the winter, and begin to blossom the following spring. Some young seedlings from seed sown as soon as it was ripe last year, removed to a box placed outside a south window, without any protection, are now showing young blossom-buds and will soon be in flower. The seedlings may either be left to blossom where they were sown, or be transplanted in September or October.—H. P.

Winter Aconites and Snowdrops Under Trees.—Much has been written respecting undergrowth for trees. Where this difficulty really exists, I would recommend the above to be planted thickly, as when seen in large masses they are exceedingly pretty at this comparatively flowerless season. They will thrive even where Grass will not grow, under the densest of deciduous trees.—C.

Outdoor Verbenas.—Good plants of Verbenas cannot be had except good cuttings are procurable. The best means of ensuring these for spring propagation is to keep a few store plants in pots all the summer, cutting them pretty closely in in the autumn, and giving them a shift into larger pots of rich soil. Soon afterwards they should be set in a cool house or pit from which frost is excluded, and in this way better cuttings will be ensured in spring than those from autumn-struck plants.—G.

Iris Reticulata in Borders.—Here, in Derbyshire, Iris reticulata is perfectly hardy, and I have never found the slightest difficulty in growing it. It succeeds well in almost any situation, although when grown in a warm and sheltered position its flowers are much finer than they otherwise would be. The bulbs increase rapidly if left in the ground undisturbed. —H. C.

ROSES.

WALL ROSES.

These in some instances soon become unsightly, but, planted in good soil and worked on suitable stocks, they are the finest ornaments that can be used for the adornment of a dwelling. I passed one only a few days since, the whole front of which was covered with Maréchal Niel and Gloire de Dijon, two of the best Roses that can be used for the purpose, as they are both free growing, and if properly treated and trained are very floriferous. The way to get the greatest number of fine blooms is to lay in as much of the medium-sized young wood as there is fair room for, from the ends of which the blooms come, but if spurred back in the ordinary manner they push little else but strong shoots, that become so large and gross as to be killed or injured by frost during the winter. It is to be feared that Roses have suffered much in this way from the severe one we have just passed through, and therefore much judgment and care will be necessary in the pruning and thinning to see that such wood only is left that has escaped being cut, which the colour and condition of the bark will show, for, if affected to any serious extent, it will by this have turned nearly black, or be full of dark spots, arising from decay of the parts. Maréchal Niel is very liable to become affected in this way, as is also the climbing Devoniensis, a superb Rose for walls and a very robust grower. The colours of the three mentioned being all pale, they look far the best against red brick, which shows them off to advantage. The difficulty with many is the training, but if the walls are trellised over with galvanised wire, or simply have the same strained horizontally along every other course, the matter is an easy one, as they can then be tied securely and the use of nails and shreds abolished. A trellis, however, put up diamond-fashion, with the wires about 9 in. apart, looks best, and costs but little more, and such a one answers well for the support of all kinds of creepers.

The Banksian Roses, both yellow and white, are capital wall plants where there is much to space to cover, and are great favourites with many for cutting, their small miniature clusters of flowers being just the thing for dressing glasses or working up in bouquets. These had, like the foregoing, bloom on the young sprayey wood of the previous year, and only require thinning out in the summer to admit plenty of light and air to ripen and harden it up. Banksians do best on a south aspect, and so also do the Maréchal Niel and climbing Devoniensis, both of which are rather tender, especially in early spring when making fresh foliage, but the Gloire de Dijon is so hardy that it will succeed almost anywhere, and when in partial shade the flowers come beautifully tinted, and are altogether much richer in colour than when more fully exposed. If we would have the Tea kinds safe, the only place to plant is at the foot of low walls, or make up narrow borders near the same, where they can be protected by straw hurdles, or something of that kind, to shield them from the severity of the weather. Mulched and managed in this way, the tops may be preserved intact, and fine blooms may be obtained for exhibition or other purposes. One of the best growers I know of these lovely sweet-scented flowers has screens made of Reed, Gorse, or Bracken, whichever comes to hand first, and these he puts up by means of a few posts and rails, so as to form a succession of barriers against wind and frost, the latter of which is warded off in winter by placing others of lighter make as copings over the top. Cared for in this way, the plants are never injured at any time, and therefore are always strong and vigorous, quite different from what one often sees under less favoured circumstances, when they are sometimes so crippled as to be unable to break again.—S. D.

Fairy Roses.—Neat, bushy little plants of brightly-flowered Fairy Roses at all times meet with a ready demand in Covent Garden, where they may now be found in abundance. Considering their easy culture and their usefulness, they might with advantage be grown more largely than they are in greenhouses and windows. They are grown as follows:—Cuttings, consisting of the young tops, are inserted in pots of sandy soil in May or June, and placed in a warm house where they can be shaded from direct sunshine until they are fairly rooted. They are then potted singly into 4-in. pots, using sandy loam and leaf-mould. When these pots are filled with roots they are shifted into 5-in. or 6-in. pots, kept in a light, airy house, where they receive abundance of water at the roots, and by the following spring bushy plants, well furnished with deep green leaves and a profusion of buds and blossoms are the result. It is necessary to fumigate occasionally to keep down green fly, to which these little Roses are

Flower of Senecio pulcher (natural size).

subject, and frequent syringings on fine days greatly improve their growth. In vases in rooms such plants last a long time in perfection, and they furnish sprays of green leafage and buds for bouquets and other floral arrangements.—C.

Pruning Roses.—The method of pruning Roses usually adopted cannot be considered a good one; for, instead of the trees increasing yearly in size and vigour, they are, when established, kept nearly at the same size. What plant is more lovely isolated on an open lawn than a spreading, naturally grown Rose? The best I ever saw had simply their heads relieved of the weakest shoots, the strong branches being allowed to grow at will. In a few years large branching heads, furnished with long garlands of blossoms, were the result.—S.

Cesspool Manure for Grass.—If ground peat charcoal is used in cesspools, a first-class manure will be made almost equal to the best guano at about a quarter of the cost. —Rustic.

Gooseberry Caterpillars.—Some years ago I had a large garden half a mile from any other, and my Gooseberry and Currant bushes were yearly infested with numerous caterpillars. After trying various things ineffectually, I found white Hellebore a specific, pouring boiling water over it, and when cold, syringing the lower leaves of the bushes on a dry day on the first appearance of the caterpillars. All appeared to be poisoned by a single application. I continued to use it for three successive seasons, and for several years after my garden was free from these pests.—Anonymous.

Myrobella Plum for Hedges.—I think that Myrobella Plum promises well as a hedge plant, but it does not seem to like damp soil. I planted the two ends of a somewhat neglected field adjoining my garden, and find that at the top and bottom of the field where the drainage is good the Plum has grown well, but in the centre, where the soil was rather wet, it has made very little growth. —George H. Wilson.

Bottom-Heat in Frames.—I have given these forcing frames much attention, and for the information of others I will relate how to properly construct one. Make a wooden frame, on four legs, 9 in. deep, 3 ft. long, and 2 ft. wide, with a bottom, and have a round hole, 8 in. or 10 in., in centre of same. Now get made a tin trough—say 21 in. by 18 in., and 2 in. deep; have a small tin pipe ¼ in. in diameter, about 6 in. long, soldered up through the bottom of the trough at one end to within ¼ in. of the top; at the other end have a feeding pipe ½ in. in diameter, with screw top for the purpose of filling; it should be 9 in. long, and soldered at the other end inside the trough about ½ in. from bottom, that the water may flow out. Place the trough in the case, a small hole being made in bottom for drain-pipe. Now get a slate (or two, if one large enough is not to be had) the size of the bottom of case, and place it over trough and cement it round with Portland cement, to keep in the steam (I use slabs of baked clay ½ in. thick, which is very porous); fill the trough with water, place underneath a lamp (mineral oil) about 2 in. from the bottom of boiler. A sun burner ⅞ in. thick is the best to use, and large enough. The reason why that style is best is you use a conical chimney, which you can cover with a cylinder of thin sheet iron, and by having a small hole punched the size of a shilling, 1⅛ in. from bottom through it, you can regulate the flame, it being a protection to the chimney from draughts or splashing of water. Now, supposing your glass frame is made, you can place it in, but means must be taken to ensure ventilation by having openings 3 in. or 4 in. wide at back or sides. You will now have a moist heat, which is the object in view, not a dry one, because the steam under the slate bed keeps the Cocoa-nut fibre moist without injury to seeds or cuttings, and none of the fumes of the lamp can get in. If the ventilation is perfect you will have no drip; 75° is enough. A thermometer is indispensable. If required for outdoor use simply board up round the legs of the frame, making holes near the bottom to admit air to enable the lamp to burn.—Petros.

Snowdrops in Masses.—These delicate harbingers of spring are now in full beauty; but to be able to see them in perfection they must be allowed to thoroughly establish themselves in masses. On ground that has been dug their purity of colour gets dimmed through heavy rains, but in permanent positions, carpeted by Moss, Grass, or Ivy, they are simply exquisite.—J.

Help for Ireland.—We hear that the sum of £100 has been received from Messrs. Sutton & Sons, the Queen's seedsmen, Reading, as a donation towards the Duchess of Marlborough's Relief Fund; and we understand that the same firm has just presented 100 bushels of their celebrated disease-resisting Potato Magnum Bonum

to Mr. E. Purdon, of the *Irish Farmers' Gazette* Peasants' Seed Potato Fund, besides a large quantity of the same variety to the Irish Church Mission at Connemara, for distribution among the population who are in such distress in that district.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 29.—Boxing and potting Pelargoniums; propagating Verbenas, Mesembryanthemums, Lobelias, and Ageratums; potting off spring-struck Lobelias and Petunias; cutting up a large Dendrobium nobile, and making three plants of it; sowing annuals, also Scotch Kale, Brussels Sprouts, Savoys, Cottager's Kale, and a little Autumn Giant Cauliflower; likewise sowing Grass seeds in bare places on lawn; also more Radishes, Walcheren Cauliflower, and Celery; putting in Purple King Verbena cuttings and Pink pipings; plunging Rhododendrons, Azaleas, and spare Lilacs; putting in another forcing of Seakale, and covering up a number of crowns out-of-doors with flower-pots, over which soil is put to keep them as late as possible; moving Salvias to cold pits, also Balm; tying up Lettuces to blanch; levelling Celery land for Peas; digging in litter round Globe Artichokes; top-dressing Japan Lilies with peat and sheep manure; earthing up Cucumbers and Cabbage plants; clipping Holly hedges; hoeing among Wallflowers, Sweet Williams, and Lettuces; sowing Green Curled Endive, and All the Year Round and White Cos Lettuce; also Long and Red and White Turnip Radishes; drawing drills for Carrots and Beet; hand-weeding and Dutch-hoeing amongst autumn-sown Onions; making new Mushroom bed under north wall for summer use; earthing up Potatoes in frames.

March 30.—Putting Hollyhocks out-of-doors, and potting off bedding plants that are established into cold pits; preparing border for Carnations; top-dressing pot Vines with loam and manure, giving them a little Standen's manure once a week, and watering them every other day; pruning Roses; making alleys deeper between Asparagus beds with a view to afford them better drainage; sowing the main crop of the following sorts of Carrots, viz., Early Horn, Early Nantes, James's Intermediate, Long Surrey, and Altrincham; also main crop of Beetroot; potting spring-struck, Petunias, Heliotropes, Salvias, and Verbenas; renovating linings round frames; hoeing amongst Strawberries; potting Azaleas, Camellias, Cytisus, Palms, and Ericas; also potting spring-struck Pelargoniums, Alyssum, Coleus, seedling Petunias, and Balsams; placing the latter in Cucumber-pit; sowing Solanum capsicastrum and French Beans in heat, and another frame of Radishes; planting China Roses; beginning to plant Strawberries, taking them up with a ball and planting them with a trowel; also putting out Cucumbers and transplanting Balm.

March 31.—Sowing Leeks, also Vegetable Marrows and Ridge Cucumbers; putting in cuttings of Dahlias and choice sorts of zonal Pelargoniums for winter flowering; pricking out Celery in boxes; also Golden Pyrethrum and Tagetes signata; clearing off Seakale beds and getting them forked up; sticking Peas and earthing them up; potting Ghent Azaleas, Dielytras, and Spiræas; sowing Peas, Long-pod Beans, Asparagus, and Spinach; planting Pansies, Neopolitan Violets, and Sweet Peas; putting in cuttings of Iresine and Alternanthera; digging land for permanent Seakale, and manuring ground for remainder of autumn-sown Cauliflower; placing Celery plants in cold pits; earthing up autumn-sown Cabbage; shifting Strawberries, the fruits of which are swelling, into a warmer house, and removing those which are ripening fruit into a cool Vinery, in order to improve their flavour; top-dressing Strawberry beds.

April 1.—Preparing old Rhubarb ground for Potatoes; sowing Self-protecting Broccoli and Autumn Giant Cauliflower in frames; planting Myatt's Prolific Potato, and preparing sets for the main crop; sowing the following sorts of Broccoli—Early Purple Cape, Early White Cape, Walcheren, Snow's Winter White, Adams' Early White, and Early Purple Sprouting; also Dwarf Green Curled Savoy, Early Dwarf York Cabbage, Asparagus, and Green Curled Kale; potting off late-sown Tomatoes, Lobelias, and Melon plants; forking up the ground amongst the Cauliflower plants left in the frames to come in early, and giving them a top-dressing of rich manure; potting Petunias and Fuchsias; sowing Cabbage and Cauliflower to be ready September 1; also more Parsley, Alexandra and Neapolitan Lettuce, Early Dutch Turnips (to be ready June 10), Early Horn Carrots (to be ready June 19), and main summer crop of Cucumbers; transplanting Cabbage plants in drills; also last of autumn-bed in the open ground for Radishes; digging vacant borders; earthing up Cucumbers; salting Asparagus and Seakale land; potting Ferns.

April 2.—Sowing Mustard and Cress, Balsams, Asters, and Cockscombs; puttiug in cuttings of Coleus and Alternantheras; washing all the Roses with Quassia water to keep down green fly; giving Broad Beans a little earthing; watering Carrots, Asparagus, and Potatoes in frames; clearing off Brussels Sprouts stumps, and getting the ground manured and dug; sowing Asters, Stocks, Sweet Peas, Lupines, Sunflowers, Carnations, and Larkspurs; planting out Lily of the Valley and Hollyhocks; pricking out Celosias; putting scented Verbena cuttings, and moving Mignonette into cold frames; stopping shoots of Cucumber plants that are growing freely; sowing main crop of Beetroot, Salsafy, Scorzonera, all hardy herbs, including Borage, Angelica, and Fennel; planting Strawberry plants, and more Cauliflowers and Lettuces; likewise Pinus austriaca and Yews and Berberries: also Lily of the Valley, and a bed of Carnations; putting Ageratums, Salvias, Petunias, and Verbenas into cold pits, and getting Lilacs out-of-doors; staking Hollyhocks and Mignonette.

April 3.—Potting sweet-scented Verbenas, Fuchsias, the forward Tomatoes, and Sweeet Basil; planting out Melons in manure frames; removing bedding plants from Vineries in cold pits to harden, and thinning Grapes where required; looking over Strawberries in bloom, and picking off all weak and late blooms; also getting another batch into warmer quarters; rolling down all gravel and turf that require it; earthing-up Broad Beans, also autumn-sown Cabbages; mowing Grass verges, hoeing among growing crops, clearing Violet beds.

Greenhouses.—The preparation of bedding plants, both from seeds and cuttings, is now the most important indoor operation. If the sub-tropical plants were sown, as recommended, a few weeks ago, they will now be ready to prick out or pot on, as the case may be. After that, till now growth has started, keep them close and shaded, and then grow them in as cool a temperature as is compatible with health and sturdy growth. Seedlings of Amarantus, Perillas, Cineraria maritima, and others of a similar nature, may be pricked off into boxes and grown in an intermediate temperature. Calceolarias, Verbenas, Gnaphaliums, and Lobelias may be planted out in turf pits, and covered with straw hurdles, mats, or frigi domo. As we have not the convenience for turf pits, we plant them out in trenches that have been prepared for Celery, and cover wlth evergreen boughs. Many Pelargoniums, for want of room, are treated in the same way, and hitherto the plan has been successful. For vases and basket beds, the Ivy-leaved Pelargoniums—many varieties—are invaluable, and cuttings put in now will make good plants by bedding-out time. Amongst other appropriate creepers for such purposes may be named Cobæa scandens, Maurandya Barclayana, Convolvulus major, and Tropæolum canariense, all of which are best raised from seeds. Indoor plants now starting freely into growth must be encouraged. Stake plants in pots as requisite, bearing in mind, however, to use as few for that purpose as possible. As the young shoots lengthen they should be tied out at once to the principal supports. Newly-potted plants should be kept in the warmest corner of the house for a long time and excluded from cold draughts, but to plants in active growth plenty of air should be admitted and abundance of water given. Introduce Mignonette in pots for summer blooming. Rhodanthes are charming plants both for summer and autumn decoration; therefore sow some at once in 4-in. and 6-in. pots or in pans, and when ready prick the young plants out into pots, keeping them near the light and pinching them at the third joint. Hard-wooded greenhouse plants of all descriptions, except Azaleas, which are better moved later on, should immediately be potted. In all cases see that the ball of roots of every plant which has to be moved is thoroughly moistened beforehand; this should be attended to the day previous to potting, so as to give time for the water to drain off. Do not further disturb the roots than by the removal of the drainage crocks from the bottom of each ball; ram the new soil with the potting-stick until it is as close and solid as the ball of the plant; otherwise, when water is given afterwards, it will pass off through the new material, leaving the roots so dry that death or an unhealthy condition is sure to follow. All plants, large and small, should be placed sufficiently low in the pot for it to hold enough water at one application to moisten the soil, as where the watering of a plant has to be done in two or three applications the whole of the surface alone gets moistened.

Flower Garden.—Climbing Roses, Clematises, Virginian Creepers, Wistarias, and other climbers will now require attention as to pruning, regulating, and nailing, and any that need additional stimulus to ward off parasites and promote more vigorous growth should be top-dressed and mulched. Herbaceous plants may now be divided, regulated, and re-arranged; many kinds that are just starting into growth, such as Pyrethrums, Potentillas, Asters, Phloxes, and Delphiniums, will bear division without the least apparent check, and retain their vigour longer than when left in the same position for years. When re-planting, take pains to arrange the plants, both as to height of growth and colour of flowers, in order that the tall growers do not overshadow the dwarfer kinds. When the arrangements are finished, any vacant spaces there may be will come in for the sowing, or planting out of Sweet Peas, Lupins, Mignonette, Stocks, Asters, Zinnias, and other annuals, all of which add both to the beauty and interest of such borders. Cuttings of Herbaceous Phloxes put in some time ago, and now rooted, must be potted off. For want of room or time we had to put in a number of cuttings in a 3-in. pot; these have been potted off singly, one in the same sized pot. A few Phloxes cultivated in pots are very useful, and make a distinct feature in the greenhouse or conservatory about the month of September. The plants for this purpose should be potted as soon as they are fairly established in 6-in. pots. They will each produce one spike of bloom, and after this they should be placed out-of-doors. The plants in beds have made considerable growth, and it has been necessary to place the sticks to some of them. This must be done early, as the stalks snap off in a high wind close to the surface of the ground. Pyrethrums belong to a class of hardy border plants that are not sufficiently known. The large flowers, in form like a double-quilled Aster. are freely produced in June and July. They are also perfectly hardy, and are increased by division of the roots. Our plants were potted in the autumn, and have been wintered in cold frames; they are now planted in beds in rich soil.

Shrubberies.—The pruning of evergreens should be finished at once. Shrubbery borders should be lightly pointed over, taking care not to injure the roots in the operation or to disturb any bulbous plants that may be growing amongst the shrubs. Isolated specimens of newly-planted trees, especially if large, are much benefited by a few shrubs being planted around them for a year or two, to act as a protection from wind, frost, and drought; after the trees get established the nurses may be removed. Prune, where necessary, Ivies on walls, and fasten any in danger of falling away from them. Uncover Myrtles, Magnolias, Clematises, and other half-hardy plants on walls, and otherwise put them in order for the summer. Plant and re-arrange flowering deciduous shrubs, keeping in view ultimate effect, and so dispose of the stronger-growing varieties as not to overgrow the more delicate kinds. Even Hawthorns, beautiful and desirable though they be, frequently occupy the front rank of mixed shrubberies when they would have been better placed further back, or set in groups. The best for dressed grounds are Paul's Double Scarlet, a splendid variety that merits extensive cultivation, Multiplex (the best double white), Punicea (single scarlet), and Rosea superba. The double varieties just named are splendid subjects for pot culture. Mulch all newly-planted trees with leaf-soil, manure, or spent tan; top-dress Hollies, Rhododendrons, and such plants as may require stimulating, with rotten manure and soil.

Vegetables.

Cauliflower plants from frames may now be planted out in well-dug highly-manured ground—a planting trowel being used to remove them in order that as much root as possible and a good ball of earth may be secured—planting them 2 ft. apart each way, which for this crop will be ample space. Sow a full crop of Savoys and Broccoli; sow, also, some seed of Asparagus in lines 18 in. apart; likewise successional crops of Radishes, and occasionally some Lettuces, both Cabbage and Cos kinds. Finish transplanting Onions, and sow the summer crop at once. Sow Round Spinach between rows of Peas, or in some other places, in quantity sufficient to meet the demand; sow also some of the New Zealand Spinach in heat for a summer and early autumn crop; this variety often affords fine succulent leaves when ordinary Spinach cannot be had. Of Carrots sow a full crop in deeply-trenched ground, which should get a good dressing of fresh air-slaked lime. Sow some small kinds of Turnip in lines 1 ft. apart, or in beds 4 ft. wide, on warm, light soil. Earth up and stick Peas as they advance in growth; any exposed to cutting winds should have the assistance of a few evergreen branches to break its force. The following are first-rate sorts for sowing about this time—viz., Champion of England, Laxton's Prolific and Quality, Veitch's Perfection, Dickson's Favourite, M'Lean's Best of All, Prince of Wales, Wonderful, Fairbeard's Surprise, Victoria Marrow, Knight's Tall Marrow, British Queen, and Ne Plus Ultra. Transplant Cabbages as required.

As Rhubarb is a deep-rooting, gross-feeding plant, in all cases it should have rich deep soil, and if it be of a heavy, retentive nature, some old, exhausted tan, leaf-mould, wood-ashes, or sandy road-drift, if such can be procured, all mixed together, with 6 in. or 8 in. of good rotten manure, should be mixed with it, trenching the ground 2 ft. or 2½ ft. deep, plant-

ing 6 ft. apart each way. A crop of Radishes, Spinach, or Lettuce may be had off the ground between the rows before the Rhubarb makes sufficient growth to interfere with them. Existing beds of Rhubarb will be much benefited by heavy drenchings with strong manure water during the next two months. Now is a good time to make a fresh plantation of herbs; fork up the underground creeping roots, prepare a piece of ground in size proportionate to the supply required by digging and putting in a fair amount of manure, forming it into a bed about 4 ft. or 5 ft. wide; then take an inch or two of the soil off the top, lay on the roots not too thickly, and cover them with the soil that was removed, leaving the surface smooth. Growth will soon commence, but the produce will not be so soon ready as from an established bed; consequently it will be well to leave a portion of the old plantation undisturbed until that from the new one is ready for use. Camomile, Pennyroyal, and similar herbs, where required, should be planted in similar beds, putting in rows 1 ft. apart small pieces divided from the old plants. Sage is best grown from cuttings struck in the latter part of summer, when they root freely; such as were struck at that time can now be planted in rows in a bed. Lettuce from frames and under the protection of south walls should now be planted out in well-prepared and richly-manured ground—the richer the better—in order that they may be grown large and crisp, and also to prevent their running early to seed. Plant them 15 in. asunder in the rows, with the same distance between the rows. In taking them up use the planting trowel so as to check them as little as possible.

House and Window Gardening.

Sweet Peas as Basket Plants for Windows.—Baskets of Sweet Peas suspended in the window are elegant objects, so gracefully do their trailing stems and foliage fall over the basket on all sides. To have them in bloom in summer and autumn, the seed should be sown now, in pots placed in a frame or warm window. About twenty Peas in each 4-in. pot will be sufficient; and when the young seedlings are up and require more space, they should be turned out of the pots and planted in the baskets—three or more pots in each, according to its size. The baskets should be thickly lined with green Moss, and the soil used should be rich and light. As the Peas grow liquid manure should be given freely, and the baskets must be hung near the glass. Keep the blooms gathered as they begin to fade; and if a little artificial manure be given late in summer, the plants will bloom far into autumn.—E.

Iris reticulata in Windows.—During snowy or wet weather the beauty of this valuable Iris, when grown in the open border, is often to some extent lost. It therefore requires to be either covered with a hand-light or potted, in order to preserve its flowers. We lately saw some in pots and pans, in a nursery near London, which had been taken from the open ground whilst in full bloom. Placed in a cool house, it keeps in perfect condition for several weeks, and it fills the whole house with its scent. For filling windows this Iris might be used extensively; and if grown in pots or pans, plunged in a bed of ashes or soil during summer, and taken indoors when cold weather sets in, beautiful plants of it in full flower might be had much earlier in the year than they could be obtained in the open air, and they would form fit associates for Cyclamens, Primulas, and similar decorative plants.—C. S.

Flower Pots in Rooms.—The pots in which plants are grown in rooms should be kept clean. Even with careful watering, the surplus water will sometimes be allowed to stand in the saucer, and in consequence the outside surface of the pot will become covered with a layer of whitish or greenish matter. A properly baked pot is very porous, and allows the air to penetrate through it to the roots of the plant, which is absolutely necessary to its proper nourishment and healthy growth. As the dust impedes the transpiration of the leaves, so does the deposition of this whitish or greenish matter on the outside of the pot prevent the air from passing through it into the ball inside. Wherever it occurs, therefore, it should be carefully washed off. Frequent loosening of the surface soil, especially when the plants are watered with liquid manure, and the removal of every weed are, for the same reason, to be recommended.—B. R.

Flower or Fern Boxes.—A pretty and effective stand for Ferns or flowers may be constructed in the following manner:—Procure a box about 2 ft. long and 6 in. wide, and make four blocks for supports 3 in. high; then cover the whole, with the exception of the back, with virgin cork, and finish by giving a good coating of oak varnish. The cost of such a stand is not more than 2s., and it will prove a very useful ornament when placed in a room or in bare and open spaces in the greenhouse.—W. A. G.

Variegated American Aloe.—The uses of Agave americana variegata for decorative purposes can scarcely be too much dwelt upon. For halls, staircases, and lobbies, as well as for its more frequent positions on terraces and pillars and in conservatories, it is invaluable. There are, however, many places of this description where this species would be too large and out of harmony in its proportions with adjacent plants and other "fixings." For such places, there are many smaller species of Agave, which are just as easily grown, and quite as ornamental. Those who wish for information as regards varieties can see a large collection of them at Kew Gardens, and can purchase plants from the leading London nurserymen. They are easily grown in any loose soil, and if well attended to may be kept in vigorous health for years.

Variegated American Aloe (Agave americana variegata).

GLASSHOUSES & FRAMES.

DOUBLE-FLOWERED SEEDLING PETUNIAS.

Finding these so exceedingly useful during the greater part of last summer and autumn for greenhouse and conservatory decoration, as well as for bedding, I would strongly recommend any one having such places to keep gay, to get a packet of seed, of the double varieties, and sow it at once; double kinds being best adapted for pot culture and not so suitable for turning out, their flowers being too heavy to withstand the effect of wind and wet, which, towards the end of the season, sadly mar their beauty. By sowing thus early, plants may be grown to a large size and had in full bloom by July, if nursed on for a time in a warm greenhouse, and then placed in cold frames or a light house where they can get plenty of sun. This renders them short-jointed, and much more floriferous than they otherwise would be, as the least shade draws them up weakly, and makes their branches so puny as to require support. The best I had were plunged out-of-doors in a bed of ashes to keep the pots cool, and thus prevent the soil drying too rapidly. This kind of treatment appeared to suit their requirements exactly, as they grew close and dense, a condition aided by having the points of the shoots nipped out just before the plants received a shift into larger pots.

Although double Petunias may be propagated by means of cuttings, seedlings are preferable, as they grow stronger and give little trouble; but when any of very superior merit show themselves it is always worth while keeping a stock plant of such for cuttings, which, put in now, soon strike root on a manure-bed under a bell-glass kept close for a time. The single forms make grand beds if planted where they can have plenty of room to spread, but, as they are naturally strong growers, a poor soil is best for them, if deep, so that the roots can get well down; that checks any tendency to over-robustness, and yet affords the necessary support during dry weather. Besides forming magnificent beds, single Petunias make fine masses in borders, but when used in that way they require support; the neatest and best way of effecting this is using coarse-meshed rabbit wire cut into yard lengths, which, run round and tied to a stake at the ends, forms a capital frame, through which they thread their shoots and completely hide the wire with their gay blossoms and foliage. There are many other plants of a similar character for which a trellis made in this way answers well, and, as they last for years, nothing for the purpose can be more cheaper or more handy.

As Petunia seeds are very small, they should only be slightly covered at the time of sowing, otherwise the young plants are unable to push through the soil. Pans for such seeds should be filled nearly full with rough leaf-mould, and on the top of that should be put 1 in. or so of finely-sifted soil, made perfectly level and smooth. That done, the next thing is to give a gentle watering, and then they should not be disturbed for a few hours, when all will be ready for sowing. This should be done thinly, and a little silver-sand sprinkled over the seeds, when, if placed in a moist heat, they will soon germinate, especially if the pan be covered with a sheet of glass, or kept dark by a piece of paper for two or three days, as by that means evaporation is intercepted and a more uniform warmth maintained. S.

RAISING ANNUALS.

Of annuals for the flower garden that rank first are the Asters, Stocks, Verbenas, Phlox Drummondi, Marigolds, Antirrhinums, annual Chrysanthemums, Petunias, Violas, Pyrethrums, Mimuluses, and Lobelias. None of these require any bottom-heat whatever, being far better without it; and, if sown and attended to as follows, few failures will arise:—

Prepare some boxes 18 in. long, 12 in. wide, and 3 in. deep, which are a convenient size to remove about, and will hold an ordinary packet of any of the above varieties of seed. Have ready a compost of loam and leaf-mould or decomposed manure, with plenty of sand well mixed. Pass one-half of the compost through a ½-in. sieve; put the rough portion in the bottom of the boxes, which should have a cavity for drainage. Next put the portion of compost not sifted, finally finishing with fine soil passed

through the sieve. Cut a piece of ½-in. lath the width of the box, and by slightly pressing its edge into the soil you will make miniature drills in which to sow the seeds. After sowing, cover slightly with fine soil. Great care is requisite in watering. Never allow the soil to get dry. Either a fine rose or a syringe should be used, or, better still, an old hair-brush. Use the water in a tepid state, dipping your brush into the water, and a gentle shake over the soil will water in such a manner as not to disturb the smallest seed.

Next come the annuals the seeds of which require the aid of bottom-heat to assist germination. Many are the plans offered to the public for the purpose; but fermenting materials have done, and still do, for many, being the cheapest and, if properly managed, the most efficient. A simple plan is to make a strong box, of any convenient size, 18 in. deep; place in any corner of your greenhouse, or under a frame; fill to within a few inches of the top with fresh horse-manure made firm; on this stand your boxes or seed-pans. If a spare light is at liberty, on which to cover the top, so much the better, as it keeps confined the moisture arising, which assists in germinating the seeds. The most difficult seeds can be started in this rude structure—Acacia, Amarantus, Begonia, Gloxinia, Zinnia, Thunbergia, Celosia, Cyclamen, Primula, Cineraria, Calceolaria, and many others; or for the starting of bulbs of Begonias, Gloxinias, Caladiums, and Achimenes, this structure will do, and, if properly made at first, will retain heat sufficiently long to start a batch of either. J. S.

Show Pelargoniums in April.—These must now be kept fairly moist at the roots, or they will lose their lowermost leaves, leaving naked stems to view, and once lost they are never regained. The most robust of the plants, having a stocky growth, should be allowed to grow on for flowering early; those of taller growth, and having the appearance of becoming drawn, should be stopped and induced to break again. They will soon do this, and if they flower later they yet yield a greater amount of bloom. This is an important month with the Pelargonium. The plants should be near the glass, but in an airy position, at the same time not subject to cold draughts of air. This is a point of importance, and respecting which the growers of Pelargoniums for market are very particular. Fumigation must be particularly attended to, for when the days are bright and sunny aphides will make their appearance, and closely infest the points of the branches, and they need to be kept under. Watering, too, at this season requires more than ordinanry care and judgment. Enough is required to merely moisten the balls of earth about the roots and keep the foliage green and fresh, but no more. A superabundance of water in dull, sunless cold weather leads to material harm. When the sun is warm and the atmosphere drying, a syringing overhead will be found of great value. Any re-potting required should be done at once, but a large shift should not be given just now; a plant requires the next largest-sized pot only so that the roots may speedily reach the sides. By tying out the side shoots, so as to give space in the middle, the plants can be trained into even shape, and the foundation of good specimens laid. The more delicate fancy varieties—the "ladies' Pelargoniums," as they have been termed—require similar treatment, but much care in watering; and they should have the warmest part of the house in which they are growing.—D.

Culture of Balsams.—These plants are exceedingly useful during autumn, both for conservatory and sitting-room decoration. They may be easily grown into specimens 18 in. to 20 in. high and 3 ft. in circumference; or, with a little extra care and a suitable place in which to grow them, they may be had 3 ft. high and as many through. I have grown them many years ago 4 ft., and occasionally 4½ ft. in diameter. Balsams have naturally a tendency to run into many varieties, the seed of one plant scarcely ever producing two alike. The double Camellia-flowered varieties are those which are most esteemed, their blossoms sometimes rivalling in beauty those of a finely-striped or flaked Carnation. In order to secure successions of bloom, seeds should be sown at two or three different times between the middle of March and the end of April. As the Balsam is of a vigorous habit, it is not important what kind of soil is used, provided it is of a light nature and tolerably rich. When the seeds are sown, the pots containing them should be plunged in a mild hotbed, and in a few days the young seedlings will make their appearance. As soon as they are sufficiently large enough to handle, they must be potted into 3-in. pots in soil of the same temperature as that from which they have been taken. They should be potted as deeply as possible without burying the lower leaves. At this period of their growth the best position for them, when it can be afforded, is a small hotbed, where they can receive the

Carnation Striped Balsam.

treatment necessary to ensure a healthy growth. Great care must be taken to keep the plants as near the glass as possible, or they will soon grow up lanky and weak. When they have taken hold of the new soil, they should have a little air given on all favourable occasions. This is essential, in order to ensure a stubby robust growth. When the pots have become filled with roots (but not pot-bound), they must be shifted into pots a size larger, an operation which must be repeated till they are potted into the size in which they are intended to bloom. Many are satisfied to bloom their Balsams in 7-in. or 8-in. pots, and if they are healthy, useful plants may be grown in that size; but to have fine specimens, 3ft. or 4ft. in diameter, fit for exhibition, they must be grown in 12-in. or 13-in. pots. As soon as the lower shoots can be got hold of, they must be tied or pegged down, and every fresh tier of shoots must be dealt with in the same manner. If they can be kept in pits near the glass, with plenty of air, and all the flower-buds picked off as they appear, till they are required to bloom, they will grow like Willows; and when the roots have thoroughly permeated the soil they will stand any amount of manure-water. When I have wished to have large specimens, I have given manure-water at every other watering, increasing it in strength as the plants increased in growth. Balsams treated in this way, and grown to the height of 3 ft. or 3½ ft., and from 3 ft. to 4 ft. in diameter, with side branches from top to bottom, all covered with beautiful Carnation-like flowers.—R.

Carnation Flaked Balsam.

Rhodanthes.—The commonly called Everlasting are among the prettiest and easiest grown greenhouse or window plant for summer and autumn. They are extensively cultivated for markets, where they usually find a ready sale. The seed is sown in successive batches in shallow wooden boxes. These are placed in gentle heat until the young plants make their appearance, when they are immediately removed to a lighter and cooler atmosphere, and, as they advance in growth, air is admitted freely to them on every favourable opportunity. When large enough to handle they are pricked off into 5 in. or 6-in. pots, putting from five to seven plants in each. They are then placed in light, airy positions in the houses or frames, where they remain until they come into flower. Sowing usually commences early in February, and continues until the end of April or beginning of May; and from this latter period onward through the summer a succession of bushy, well-flowered plants is maintained. The varieties grown are R. Manglesi and R. maculata and alba. Rhodanthes may also be grown in the open ground in fine rich soil. The seed should be sown at the end of April.

ANSWERS TO QUERIES.

1712.—**Artificial Manure.**—There is no better general artificial manure than Peruvian guano, if it is pure; but it is difficult to obtain it so. With stiff soils absolutely rotten horse manure is not so desirable as the working into it of plenty of long manure fresh from the stable, as the straw supplies fibre to the soil, and even in this respect alone is most valuable. Then phosphates, especially in the form of wood ashes and crushed bones, are good; and phosphates are largely found in phospho-guano. A very superior general manure is Clay's fertiliser, and seems to possess all the ingredients needful for plants. The manure sold by the Amies' Company also has a wide reputation; and the Potato manure sold by Messrs. Hill & Co., of Deptford, is a superior Potato fertiliser.—N.

1710.—**Worms on Lawns.**—Corrosive sublimate (Perchloride of mercury) is soluble in cold water in the proportion of 1 in 16; its specific gravity being five times greater than that of water, the quantity named in the question will require 1 pint of water for its solution, which would be accelerated and rendered more permanent by the addition of a small quantity of sal-ammoniac. On account of its rapid change of state upon coming in contact with organic substances, by which it loses the equivalents of chlorine and becomes converted into chloride of mercury (calomel), I should think its utility for the purpose named questionable. For a trial, I should suggest that you use 1¼ oz., dissolved in three or four gallons of water.—F. W. P.

1606.—**Propagating Hyacinths.**—This can be done by amateurs by keeping the offsets which come off the parent-bulbs of Hyacinths, Tulips, &c., from time to time. These may be planted in autumn in a separate bed of light, sandy soil, and in two or three years or more, according to size, such offsets will become large enough to be planted out like imported bulbs. Or seed of Hyacinths may be collected when the seed-vessels wither and begin to split, and sown out-of-doors, under more or less shelter, in soil enriched with decayed leaf-mould, keeping the bed free from weeds and decaying leaves; but under this plan the bulbs will not be large enough to bloom for four or five years.—C. L. J.

1713.—**Cyclamens, Cinerarias, and Primulas from Seed.**—Cyclamen seed, as a rule, is sown in July or August, or as soon as well matured; grown in warmth, pricked out thinly into other pots, and kept growing on until large enough to be shifted into small single pots, and still kept in gentle heat, that the growth may be continuous and without check. If seed be sown now, it should be placed in a gentle bottom-heat and the plants kept growing; but it is doubtful if such seedlings could be induced to bloom next winter. Chinese Primrose seed may be sown at once in a shallow pan in a gentle warmth; and when seedlings are large enough, prick out into other pans,

and finally pot up singly, keeping in a cool frame all the summer. Cineraria seed may be sown about the middle of June without heat, as the temperature is then warm enough. Use shallow pans here also, and in all cases the soil fine and sandy. Cinerarias should be kept in a cold frame until winter compels their being put into the greenhouse.—D.

1725.—**Cats in Gardens.**—I have found that some galvanised-iron netting, laid flat on the top of the wall, so as to project beyond on both sides, to have been of great benefit in keeping off cats. If there be any particular spot in the garden for which they have a weakness, it is an excellent plan to procure a packet of good strong pins, and, cutting off the heads, insert them into some sticks of firewood, pushing them into the mould, leaving only the points projecting. The first application of one of these points to the sole of the foot of one of these domestic tigers, when with its cleanly habits it commences to dig up a bed of Geraniums, is remarkable; and the feline tribe, being gifted by Nature with a most retentive memory, do not often require a second, but, with that species of freemasonry which exists among them, you will soon find your garden possesses an evil reputation, and as a place to be avoided. Some people may say this is cruel; but is it worse than crushing under foot the peaceful slug, or drowning the apathetic aphis?—LEWIS W.

1612.—**Propagating Virginian Creepers.**—Cuttings of well-ripened wood should be taken during September, or not much later, to be set pretty deep in sandy soil in a sheltered situation. Layers may also be taken from the parent plant from July onwards. By these methods some well-rooted plants could be obtained, which would grow strongly the following season. Meanwhile a screen might cheaply be effected by planting a few quick-growing climbers, such as Nasturtiums of sorts, Tropæolum canariense, or Convolvulus major. As to foliage plants for a border, 8 in. appeared rather a difficult height. Possibly the following might be found suitable:—Pyrethrum Golden Feather, Mrs. Pollock Geranium, bronze tricolor; Centaurea Ragusina, silvery grey; Arabis of sorts, variegated gold or silver.—C. L. J.

1735.—**Flowers for Bees.**—The few flowers grown in a garden would not be of much assistance to the bees; what is of more importance is that there should be plenty of field flowers, as Beans, Tares, White Clover, Sanfoin, Charlock, and most kinds of weeds; also the blooms of Lime and fruit trees. The bees will gather honey near their hives if they cannot find better elsewhere. What is needed is a constant succession of bloom.—E. W.

1732.—**Plants for a Shady Landing.**—India-rubber plants, Oleanders, strong-growing Ferns, Fuchsias, Scarlet Pelargoniums, half-hardy Dracænas, Camellias, Cinerarias, Calceolarias, Balsams, and Chrysanthemums might all do on a large airy landing, but some would have to be grown specially for the purpose first. Few plants would thrive there for any lengthened period, as there would not be sufficient light. The best perennial creepers for such a position would be found in varieties of the spring-blooming Clematis, as these should bloom early in the summer in the sunshine, but bloom later if in the shade. Of annuals, the Canary creeper, the Lophospermum scandens, and the Scyphanthus elegans will do very well.—A.

1726.—**Cucumbers in Frames.**—If a hotbed intended for the growth of Cucumbers has been properly made, and the heat is gently rising, good strong plants should be got, either by begging or purchase, and be planted out at once, care being taken to put a thin sod of turf under the roots to prevent the heat rising and burning the young tender roots. The soil should be in the form of a hill in the centre, and about 3 in. deep at the sides being added to as the plants grow and the roots show on the surface, until it is 6 in. in depth all over the bed. A little steam will do no harm, but too much may soon kill the plants. To avoid this the lights should at the first be kept tilted about ½ in. at the top to allow superfluous steam to escape. To sow seed when the bed is ready would be to allow all the energies of the bed to be used simply to raise plants instead of growing them. Telegraph, Duke of Edinburgh, Model Green Gem, Blue Gown, and Tender and True are all good frame kinds.—D.

1729.—**Cucumbers in Pits.**—A Cucumber pit differs from a frame in this respect—that a pit is composed of brickwork, and a frame is of wood, and movable. With a pit, the well-prepared stable-manure is thrown into the pit, carefully built into the interior, and gently trodden to settle it down; then the needful soil is placed on the surface, raised like a little hill in the centre, but thinner around the sides; and when the raw steam has passed off, the plants are planted into the centre of the hills, and fresh soil is added as the young roots show through the soil. The manure should be well prepared by frequent turnings and waterings until it is equally heated; and after it has been placed in the pit, a little ventilation should be given behind. The plants may be put in about the third or fourth day, and be lightly shaded on hot sunny days. A good soaking of tepid water should be given at least once a week after the steam has abated. If the brick pit be built with open walls, or has pigeon-holes round the sides, some thick linings of manure

An Everlasting Flower (Rhodanthe Manglesi).

may be built up round it, and the heat will pass into the frame, and aid to prolong the inside warmth.—A.

1751.—**Mice in Gardens.**—You must catch them. Get half-a-dozen of the cheap mouse-traps, single ones, and bait with toasted cheese rind, or toasted bacon rind, and put them down at dusk by the Peas. The traps are about two-pence each, and have a door which is closed with a circular wire spring. You will catch all the mice in a few nights, but you must not kill the mice in the traps.—MAJOR.

1714.—**Worms in Fern-cases.**—Lime-water—made by placing a double handful of fresh, hot lime into a gallon of water, stirring it well, and allowing it to stand for a few hours before using—makes a solution that is usually deadly to worms and not injurious to plants. The water need not be sprinkled over the foliage. Allow the soil to get rather dry first, then give a watering in the evening.

1735.—**Plants for Bees.**—Mignonette is without doubt a first-rate honey-flower, as, indeed, are nearly all odorous flowers. As a rule, bees, when leaving the hive, ascend and go a considerable distance for food; but some may feed near home. Still, the Mignonette, if sown several yards from the hive, would no doubt be more attractive than if sown close by. If other bees are feeding on your flowers, you have the satisfaction of knowing that your bees are elsewhere repaying the compliment.—D.

1720.—**Growing the Potato Onion.**—The Potato or underground Onion should be planted in the late autumn, say in October or November, in sheltered places, or at once where not so planted already. The beds should be about 4 ft. wide, and the sets or bulbs planted, or rather dibbled in, about 8 in. apart each way, leaving the top of the bulb level with the soil. Have the soil well worked and manured, keep well hoed during the summer, and lift the crop as soon as ripe early in September.—A. D.

1721.—**Culture of Lilium longiflorum.**—Lilium longiflorum is one of the easiest of all this family to grow, but the bulbs should be lifted and stored in sand during the winter, as slugs, wireworm, and other ground vermin will feed on them. In pots, single bulbs should be planted in sizes of 6 in., and in good rich soil, kept fairly cool and shady in hot weather. It will do grandly in beds planted out in the spring, blooming profusely in August. Where other kinds thrive longiflorum should do well.—D.

1561.—**Steam for Forcing Frame.**—If "V" will get some Portland cement, mix it well into a paste, take a trowel and cover the whole of inside of frame, taking care to fill up all the nicks, he will then have no further trouble with the steam in frame. Before commencing the tank must be cold, and give time for cement to set before lighting the lamp again.—A. E. S.

1738.—**Annuals and Biennials, &c.**—Of annuals that are the better for transplanting—chiefly because, being tender, they cannot be sown with safety out-of-doors—are Asters, Marigolds, Balsams, Stocks, Zinnias, and Phlox Drummondi. Of these that can be sown in the open ground are Helichrysums, Larkspurs, Clarkias, Candytuft, Sweet Peas, Mignonette, Indian Pinks, Viscaria, Chrysanthemums, Malope grandiflora, Godetias, Eschscholtzia, and numerous others. Of biennials sown now to bloom in autumn, the best are the Antirrhinum, Corn Cockle, and Pentstemon, but few others may do so. Of perennials, some Delphiniums, common Carnations, and Myosotis semperflorens may bloom in the autumn; but perennials that will flower the first year are indeed few.

1724.—**Smooth *versus* Prickly Cucumbers.**—There is a certain prejudice in the market in favour of spiny or prickly Cucumbers over smooth ones, but the difference in flavour is very doubtful. Both Telegraph and Duke of Edinburgh are free and good bearers, and do well in a frame without peat; so also will Blue Gown, a prickly kind, and Green Gem, a smooth one.—D.

1723.—**Sowing Malope grandiflora.**—Malope grandiflora is a fine, showy, hardy annual, that may be sown in the open ground with safety at any time from the first of April, either in little patches or in shallow drills. Also seed may be sown in pans and raised under glass in a cold frame or greenhouse; and when the seedlings are 2 in. high the pans should be stood in the open air to harden off before planting out.—A.

1748.—**Soil for Potting.**—The best advice is not to waste time and patience over what is so valueless, but to abandon it to its natural uses, and get some suitable loam, which, mixed with sand and leaf-soil, will make really good potting soil. The great need in any soil employed in potting is to have in its composition fibre which should be natural; but probably no artificial fibre will excel Cocoa fibre refuse, which could be added to stiff loam at the rate of one-third. Leaf-soil also makes a good addition; but it soon decays, and leaves the soil in the pot hollow and open. The frequent watering soon produces congestion in the soil, and tenacious soils gets as hard as brick, preventing the roots from working, presently killing the plants.

1587.—**Mottoes for Sun-dials.**—*Amicis quælibet hora:* Any hour you like for friends. *Docet umbra:* The shadow teaches. *Allez vous:* Pass on. *Horas non numero nisi serenas:* I reckon only the bright hours. *J'avance:* I go forward. *Lux, umbra Dei:* Light is the shadow of God.

1731.—**Sweet-scented Plants for Greenhouses.**—The following sweet-scented plants I have grown in a house such as your correspondent describes with a fair amount of success:—Daphne odoratus, D. cneorum, Acacia armata, Nerium, Oleander, Myrtle, Lemon-scented Verbena, and Heliotrope, which latter will bloom nine months in the year in such a structure as that mentioned. Dwarf standard Roses also will do well. In bulbs, he would succeed with Hyacinth, Narcissus, Jonquil, Lily of the Valley, and Tuberose; and also with Lilium auratum, L. lancifolium, L. rubrum, and other Japanese Lilies, which are all powerfully scented.—LEWIS W.

1727.—**Cats in Gardens.**—Bird-lime will not keep cats out of a garden. If the garden is walled all round a good thing to do would be to cover the top of the wall with broken glass set in mortar.—AJAX.

1722.—**Plants for Unheated Greenhouse.**—A space underneath the close stage of a greenhouse may be utilised to grow Mushrooms, or to blanch Seakale or Rhubarb; or it may be used as a fowl-house, if shut off

from the inside of the greenhouse, and an outlet is made outside. If used for such a purpose of course the stage must be perfectly watertight. At this time of the year nearly all kinds of greenhouse plants will do in an unheated house. Genistas, Deutzias, Dielytras, Cinerarias, Primulas, Calceolarias, show and zonal Pelargoniums, Fuchsias, Balsams, Celosias, Globe Amaranthus, Phlox Drummondi, Lobelias, &c., may be raised from seed. Many of the showy Begonias will also do well, and help to make the house very gay all the summer.—A.

1728.—**Forcing Tulips.**—In large market-growing establishments, where the Van Thol Tulips are forced in large quantities, it is the usual rule to plant the bulbs thickly into boxes, and place them in heat near the glass. Just before they come into flower the plants are carefully lifted out and blocked in half-dozens into 5-in. pots, and each flower, expanding at the same time are thus sent to market. The Tulip bulbs mentioned in the question must have been of bad quality, and not sufficiently matured to carry flowers.—A.

1516.—**The Best Way to Clear a Lawn from Coltsfoot** is by carefully pricking out every flower. As the Coltsfoot is an annual, this prevents any distribution of seed, and consequently the plant is soon got rid of. The flowers come up in March and April before any leaves appear, and are therefore easily seen and gathered. I know this is the only effectual plan to eradicate the pest.—GEO. H. L. RICHARDS. [The Coltsfoot is not an annual. It increases yearly by means of its underground stems or roots, which spread rapidly. Picking the flowers off might do some good, but it would certainly not kill the Coltsfoot.—ED.]

1741.—**Last Year's Seeds.**—I sowed in an unheated greenhouse seeds of last year of Godetia, Dianthus laciniatus, and Mignonette, and they all came up.—C. D.

1733.—**American Blackberries.**—Plant in a row a foot apart, and train to stakes, or erect a wire trellis to train on. Three wires strained to stout stakes will do. The upper one should not be less than 5 ft. high.—E. H.

1725.—**Blood for Vines.**—I have seen it applied successfully at this season to late houses or open-air Vines, or it may be given any time during summer; but when given to Vines in active growth dilute it with water. It is not adapted for weak or sickly Vines, but is a powerful stimulant where the Vines are vigorous and are well provided with roots.—E.

1711.—**Pruning the Arbutus.**—Cut down the Arbutus next month to within 2 ft. of the ground. It will break again and make a good bush.—E. H.

1751.—**Mice in Garden.**—Use traps or poison. Dress the seeds with red lead, and place coal ashes over the crowns of bulbs. Also procure a kitten or two and train them up properly—that is, be kind to them and encourage them to live in the garden. I have a kitten that follows me through the houses, walks upon the stages among the pots, using as much care in placing its feet as I should do myself.—E.

1750.—**Leather Dust in the Garden.**—The waste from a shoe factory should be a valuable manure, and so also are the ashes. Both may be useful applied as a top-dressing to fruit trees, lightly forked in; also as a top-dressing to flower borders. The ashes will be useful for Potatoes and other root crops, especially Turnip, Carrot, and Onions.—H.

1707.—**Phalænopsis in a Stove.**—The Phalænopsis will do in a night temperature of 65° in winter. Two or three degrees less on cold nights will do no harm.—E. H.

1707.—**Phalænopsis in Stove.**—These will do well in a temperature of 60° in winter, other circumstances being favourable. P. Schilleriana will do with a few degrees less heat than P. amabilis; 70° to 10° in summer will do very well indeed. Phalænopsids are easily grown, but they require certain attention at the right time, and are rather particular as to the position in the house they occupy, preferring the shady to the sunny side. They ought also to be near the glass. Give water sparingly in winter, but the roots must never be quite dry. During the growing season plentiful supplies of tepid water are necessary.—J. D.

1582.—**White Chrysanthemums.**—Twelve white Chrysanthemums make a big hole in the varieties of that colour if for conservatory decoration. The following six are good and easily grown: Mrs. G. Rundle, Cassandra, White Globe, White Christine, Elaine (Japanese), and White Cedo Nulli (Pompone). If for cut blooms, the first four of these may be taken, and the following in addition: White Venus, Princess of Teck, Eve, Virgin Queen, Lady St. Clair, (sometimes called Empress of India), and Blonde Beauty. But the last four of these require rather high culture for a first attempt. Some of these varieties are tinged pink on the tip of the petals.—S. S.

1793.—**New Potatoes of 1879.**—*G. B. E.*—It is the rule to regard all new Potatoes offered for the first time in commerce either in the autumn of one year or in the spring of the succeeding year as being sent out in the second year, because that is the first season in which they can be grown. Thus any offered in the autumn or winter of 1878 are classed as sent out in 1879. The best kinds so offered are Woodstock Kidney and Avalanche, White Kidneys, Vicar of Laleham, (blue round), Triumph (red round), Beauty of Hebron (pale pink Kidney), and Early Purple (a purple oval or half Kidney). There may be one or two others not so well known, but all these are *bonâ fide* and distinct new kinds. Of White Rounds there are none known; as, curiously enough, of exhibition quality these are always in a considerable minority as compared with Kidneys, and even coloured Rounds. The past sending-out season has been singularly barren of new kinds, arising no doubt largely from the ravages of the disease of last summer. The best known are Pride of Ontario, an American kind, the tubers large, round, white and prettily tinted with red; Heather Bell, a Scotch raised sort, true Kidney shape, very handsomely mottled with purple; and Beauty of Kent, raised in Kent from the American Snowflake. This kind resembles the Early Rose in colour, but is round.—A. D.

1794.—**Liquid Manure for Plants.**—Which is the best liquid manure for pot Roses and general use.—FLINTMAN. [Drainings of the stable or manure heap, or sheep's manure put in a tub with a handful of salt, and a bag of soot suspended in the tub.]

1795.—**Chrysanthemum Cuttings.**—Shall I shade my cuttings now, or keep them in full sun?—A. H. I. [If well rooted they do not need shade.]

1796.—**Fuchsias Out-of-doors.**—Last autumn I bought some large Fuchsias, which had been in a greenhouse. Not having enough room in my greenhouse, can I expect to get good flowers if I put them out-of-doors in a week or so?—A. H. I. [Put them out-of-doors early in May, and they will bloom well.]

1797.—**Marechal Niel Rose.**—I am afraid that my tree is dead. The branches at the ends are turning black and dry, although it is green enough on the two principal stems. A Briar also out of the old stock is budding out; shall I cut that off?—A. H. I. [Prune back the dead shoots and rub off suckers from the stock.]

1798.—**Roman Hyacinths.**—Can these, now having ceased flowering, be made of any use for next season, and if so, how should they be dealt with?—DELTA. [Plant them out in good garden soil in a sunny position, and water freely in dry weather.]

1799.—**Spiræas Turning Black.**—I have a lot of Spiræas, fine robust plants with hundreds of heads of bloom, but as soon as they begin to break into bloom the necks go black and they drop off. I keep them in my greenhouse.—A. L. [We can assign no reason for the flowers turning black other than that the plants do not get sufficient water and air. They cannot well have too much water when opening their blossoms; and a little liquid manure would be a great help.]

1800.—**Stocks for Weeping Trees.**—I have obtained some common Birch stocks for working Betula alba pendula elegans upon. What height should I cut them for making standards for planting on a lawn? Ican make them up to 8 ft. Should they be grafted or budded, and when?—W. R. D. [8 ft. will not be too high for a good weeping tree. You may either bud or graft them as convenient. It should be done in autumn, but you might try budding at once.]

1801.—**Weeping Roses.**—I have never seen a weeping Rose except upon paper, and presume that they are either rare or unworthy of popularity. What height should the stocks be for planting on a lawn?—W. R. D. [Stocks 6 ft. to 8 ft. high. Instead of pruning back the shoots, simply thin them out, and train those left in a downward direction. There are not many Roses that weep naturally in the sense you mean, but nothing is more easy than to form a weeping Rose tree.]

1802.—**Dry Soil for Potatoes.**—Would light soil under which rag appears at a depth of 2 ft. be considered too dry for Potato growing? If so, how can it be remedied? Will watering benefit the crop? I am planting Earlies and Magnum Bonums.—PENSE A BIEN. [If you mulch the Potatoes with a few inches thick of half-rotten manure after they are earthed up, the soil will be wet enough.]

1803.—**Striking Cuttings.**—Can I strike Geranium cuttings now, and should I harden the plants before making the cuttings? [Geraniums will strike easy now in a warm house. If a little bottom-heat can be given all the better. The plants should not be hardened before the cuttings are taken.]

1804.—**Leaves of Spiræas turning Brown.**—I have some plants of Spiræa japonica in a greenhouse. How can I prevent the tips of the leaves from turning brown?—J. A. M. [Give the plants plenty of water, light, and air.]

1805.—**Cheap Pea Sticks.**—Not being able to procure Pea sticks, the best and most inexpensive substitute for Peas and Beans is asked by—S. N. [A few stout poles or stakes driven firmly into the ground, 5 ft. or 6 ft. apart on each side of the rows, will answer. These should be all of one height, which should be that of the Peas; some tar twine or other strong cord should then be tied to the end stake and passed along the line, making a turn on each stake within a few inches of the ground; and as growth progresses the next turn should be raised a little higher up, and so on until the plants have attained their full height. If the string or cord be applied at the right time, the tendrils of the Peas will clasp firmly round both stakes and strings, and will support the plants almost equal to Pea-sticks; some, indeed, think this plan best, as by it the plants are exposed to more light and air than they otherwise would be, and the pods are more easily picked without injuring the haulm.]

1806.—**Spiræa filipendula.**—I have some young plants which have started very well in a steady bottom-heat. Should they be kept in the hothouse?—H. M. E. [Gradually harden them off, and place them in a light, airy house or frame. This Spiræa is a hardy plant, and does not need either bottom or top heat.]

1807.—**Crocuses after Flowering.**—I have a number of Crocuses that I have grown in boxes and pots. How should they be treated after flowering?—ZERO. [Plant them out in the wildest parts of the garden or shrubbery.]

1808.—**Moss on Walks.**—What will prevent the growth of Moss on walks? My garden is a very old one, and this growth causes much trouble in the constant use of the hoe. [Good drainage is the only cure. Use plenty of salt in dry weather, if there are no live edgings to the walks.]

1809.—**Coal Ashes for Gardens.**—I have riddled and mixed coal ashes with horse manure for use in my kitchen garden. Is this a good manure, and am I right in using coal ashes at all?—F. [If the soil in the garden is stiff and clayey ashes will do good, but if light and loamy they are not needed.]

1810.—**Sand on Lawns.**—Does fine sand rolled into a tennis lawn help to harden the turf?—H. [A little sand would do good if put on when the ground was damp, and well rolled in; but too much should be avoided.]

1811.—**Brussels Sprouts.**—Will some one tell me how to grow these?—T. L. [Sow in beds in June; plant out when large enough in well-manured soil 2½ ft. apart.]

1812.—**Wire for Training Ferns on.**—May I use copper wire on which to train the climbing Fern (Lygodium scandens), or is there anything better?—T. S. [Copper wire will do, but a thin Willow or Hazel stick would be as good; so would strong twine or whip-cord.]

1813.—**Heat for Ferns.**—Do Maiden-hair Ferns (Adiantums) need a higher temperature than 50° to 55° at this season? I can give more if requisite.—J. S. [They would grow in the temperature named, but would do better in one 10° higher.]

1814.—**Saving Parsley Seed.**—How can I get seeds from Parsley, and when will they be fit to sow?—Loco. [Select good curled-leaved plants at once, and plant them in a sunny position in rich soil. They will ripen seed in autumn, which may be sown as soon as gathered, if necessary.]

1815.—**Heating Fernery.**—I have a glass enclosed Fernery which for some years I have endeavoured to heat during winter by means of gas, applied in various ways, but without success; my plants being destroyed by the chemical products of the gas.—K. [There are plenty of heating apparatus advertised in our columns weekly.]

1816.—**Sowing Peas for Succession.**—I have purchased the following collection of Peas, viz., William the First, First Crop, G. F. Wilson, Fillbasket, Laxton's Popular and Supreme. I have already sowed the first the first two kinds, and shall be glad to know when each of the other varieties ought to be put in in order to obtain a good succession. [Plant half of each sort at once, and the other half when they come above ground.]

1817.—**Clematis Flowering only at the Top.**—I have a Clematis Jackmani which has been planted out four years against a wall. It makes very strong growth, but all the blooms are at the top, although I train it from side to side. What can I do to distribute the blooms over the surface?—R. W. [Cut down one half the shoots to within 6 in. or so of the ground; you may then get growths from the bottom to flower on the lower part of the wall.]

1818.—**Propagating Laurels.**—When is the best time for striking these, and which is the best way to take them?—B. [Take off growing shoots 6 in. long in autumn with a little heel attached to them if possible. Place them firmly in the ground in a sheltered situation and in sandy soil.]

1819.—**Plants in Cucumber House.**—What flowers can be grown in a greenhouse which is used for Cucumber growing, the stage being shaded by the Cucumber leaves, and the heat kept at about 70°?—C. P. [Ferns and Mosses would do better than anything else in such a position.]

1820.—**Pyrethrums.**—What is the habit of these plants? I had a dozen last autumn, but lost half. What height do they grow, and are they suitable for the front line in a border (first line)?—P. [The flowering Pyrethrums form tufts of finely-cut foliage from about 6 in. high, but their flowers are borne on stems 9 in. to 12 in. in height. They would do for a front row provided you had no dwarf plants behind them. They require deep sandy soil.]

1821.—**Honeysuckles not Flowering.**—What is the reason of their non-flowering? They grew well last summer; clay soil. I have worked in a lot of manure and best road sweepings. Will this succeed in making them flower?—W. J. R. [Probably the wood does not ripen in the autumn. They want plenty of sun.]

1822.—**Tulips a Second Year.**—Will these succeed next spring if left in the ground, as is the custom with Narcissi and Crocuses?—W. [Yes; perfectly.]

1823.—**Breadfruit Potato.**—Is the American Breadfruit Potato red? and a Kidney or Round also the quality?—A CONSTANT READER. [A round, white Potato of good quality in some soils.]

1824.—**Watering Palms.**—Is it right to water Latania borbonica from the surface of the soil, or to pour it into the saucer, and let it suck up as it requires, throwing the surplus away?—C. F. H. [From the surface of course. Give it sufficient water at a time to thoroughly soak the whole of the soil. There should not be any water in the saucer. Always use water of the same temperature as that in which the plant is growing.]

1825.—**Cutting Branches of Araucarias.**—Would it hurt an Araucaria if its lowest tier of branches were sawn off? I cannot get the weeds removed, as even the second tier of branches are trailing on the ground.—ARAUCARIA IMBRICATA. [It would not hurt the plant much. Do not saw the branches off too close to the stem; and cut over the wounds with a sharp knife afterwards, and smear them over with clay. We should think, however, that by lifting up the branches with a long stick the weeds could be removed, without spoiling the tree.]

1826.—**Hyacinths Grown in Glasses.**—What is the best way of treating Hyacinths which have been grown and flowered in water with a view to their flowering in the garden next year?—RUS IN URBE. [Harden them off a little by placing them in a cool place, and then plant them out in a sunny position out-of-doors in good rich soil. Cut off all the flower-stems.]

1827.—**Propagating Variegated Thyme.**—How can variegated Thyme be propagated, and at what time of the year? Can it be left in its place out-of-doors all the winter without harm?—C. D. [It may be propagated now or in autumn by division of the roots or by cuttings

put in sandy soil under a hand-light. It is perfectly hardy.]

1828.—**How to Grow Mignonette.**—*Mark.*—Mignonette requires rich soil, a good mulching of manure, and plenty of water. If grown in pots, liquid manure is a great help to it when coming into bloom.

1829.—**Growing Cucumbers.**—*Old Subscriber.*—These may be grown without any artificial heat in a greenhouse during summer. Flowering plants will not grow well under them, but Ferns and Mosses might do fairly well.

1830.—**Winter-flowering Fuchsias.**—*Rector's Wife.*—Any kind of Fuchsia may be got to bloom in winter by proper treatment. In autumn prune back some of your plants, re-pot them, and place in a warm, moist temperature till they come into flower; then put them in the conservatory. Cuttings struck in May, June, and July will also flower in winter if the blooms are kept picked off and the shoots pinched weak till, say, November.

Horse-droppings as Manure.—*A. J. B.*—You cannot possibly have anything for mulching Roses or manuring a garden equal to horse-droppings, from which all the straw has been shaken.

Increasing Primulas.—*Beginner.*—Old plants are never so good as those raised from seed.]

Soil for Ferns.—*Beginner.*—Ferns do not need potting every year after they get large enough to occupy, say, 8-in. or 10-in. pots. The roots should never be trimmed nor injured in the least.

Striking Geraniums.—*Beginner.*—These would strike much easier in May and June than now. If you want them for bedding begin at once.

New Foliaged Plant.—*R. W. W.*—Send us a plant, that we may judge of its merits.

Todea superba.—*C. M. C.*—This requires a close, moist atmosphere. It will succeed best in a quiet unheated sunless house, under a glass shade or hand-light, or even without a shade.

Mulching Roses.—*Mark.*—Pruning should, of course, be done before Roses are mulched.

Brompton Stocks.—*F. A.*—These are hardy, and if they have been kept in a cool temperature during winter may be planted out at once.

The Way to Write Labels.—*W. H.*—Always begin at the top of the label and write towards the point.

H. Osborne.—We cannot make out what plant you refer to. Kindly write it plainly.

Wireworms in Soil.—*Gang Forward.*—Give the land a good dressing with salt if it is vacant. Well turn up the soil with a fork, and give another dressing in a week's time. It will then be ready for planting at the end of May. A dressing of quicklime would also be beneficial. Oil-cake sown on the land is a good thing; the wireworms feed on it and burst.

Annuals for Bouquets.—*W. T. B.*—The list of these given at p. 810 (Feb. 28) will suit your purpose well. They shou d all be sown by the end of April.

Eulalia japonica.—*F. S.*—Any of the large nurserymen will procure you plants of this Grass if they do not possess a stock, but probably they do now. The price varies with the size of the plants, but it is not considered an expensive one now it has become more common.

White Moss Trees.—*R. H. W.*—Do you mean Moss Roses?

Names of Plants.—*F. Sutton.*—Garrya elliptica. One of the best of hardy evergreen shrubs.——*W. C.*—Some kind of Lichen, which can only be named by a specialist.——*M. F.*—Boronia megastigma.——*Cumnock.*—Kerria japonica, sometimes called Corchorus japonicus.——*S. B. C.*—The white-leaved plant is the variegated Jacob's Ladder (Polemonium cœruleum), belonging to the order Polemoniaceæ; the white-flowered plant is a double-flowered Plum (Prunus sinensis).——*R. B.*—1, Arabis albida; 2, Daphne Mezereum; 3, Ribes sanguineum.

1831.—**Treatment of Boronias.**—What is the proper treatment for the sweet-scented Boronia after flowering?—A. K.

1832.—**Glazing without Putty.**—I have recently seen some new glass structures with the sash-bars placed horizontally, and apparently thick panes of glass laid on them edge to edge. It looks very neat, but how about its utility? I am about to put up a Vinery and conservatory about 60 ft. by 24 ft., with a division half-way, and would like to have the opinion of some one who has had actual experience of this kind of house. Is it as useful as the old sash and putty system (with sashes the other way)? The new system certainly looks good and strong. The panes appear to be kept in place with sheet lead doubled back over the lower rim. Is the system to be recommended as water-tight, weather-proof, &c.?—E. N.

1833.—**Hotbed Frames.**—I should be obliged if "G. A." (No. 1518, March 6) would tell me what kind of lamp he had the benzoline in. I have tried it, and every lamp I put under the frame is destroyed. The cement and the solder in three different kinds of lamps has come undone, and the top of the lamp fallen off; and in consequence the oil got on fire. Should there be a chimney to the lamp? What distance is the lamp from the bottom of the boiler? If "G. A." will give me all information on the subject I shall be glad.—J. M. M.

1834.—**Culture of Double Geraniums.**—Will some one give me a few directions as to the culture of double Geraniums, as I find it very difficult to grow them successfully?—ARTHUR.

1835.—**Creepers for Tops of Walls.**—I have a dwarf wall at the edge of my lawn; there is a border of flowers and shrubs level with top of wall; the coping is always unsightly. What are the best hardy plants or creepers to cover it quickly?—C. P.

1836.—**Treatment of Watsonias.**—How are these best grown, and what colours do they possess? I have planted mine with Gladioli; is this likely to produce a good effect?—W. J. R.

1837.—**Hotbed Frames.**—Will "G. A." kindly give a little more explanation of his description of his home-made frame in the No. published 6th of March. He says there that he knocked the top and bottom off the case, and fixed the pan to the bottom. Does he fix the bottom to the case again, and, if so, what is the good of knocking it off? Or, if not, how does he manage with the Cocoa-nut fibre, in keeping it in the case, and from the lamp? Why does he use the fibre. And in standing the box on two flower pots I suppose he means the boiler pan is on the pots, as it is as large as the case. And where does he fix the pipe for filling the pan?—C. G.

1838.—**Ants on Lawns.**—Will any reader tell me how to get rid of nests of small red ants, which seem to come up annually on my lawn? I want, if possible, to get rid of them without being cruel to the industrious little fellows, or destroying the Grass.—SPARKE EVANS.

1839.—**Garden Farms in Cornwall.**—Could any one give me any information as to the average size of the garden farms in Cornwall (where Broccoli, &c., are grown), number of men employed, and rent per acre?—G. B.

1840.—**Climbing Roses in Pots.**—What are the best varieties of climbing Roses to grow in pots for the greenhouse? Also best compost to grow them in?—AN AMATEUR.

1841.—**How to Make the Most of a Garden.**—I have about half an acre of ground, which I wish to turn to some useful purpose. It is open to the south-west, but enclosed on all other sides by tall trees; what vegetables can I grow to most advantage?—E. B., *York.*

1842.—**Treatment of Azalea Cuttings.**—In the early part of last summer, I put in a few cuttings of choice Azaleas. They appear to be growing a little, and I shall be glad of information as to proper time to shift them from the cutting pan, and also their after treatment.—H. J. W.

1843.—**Plants for a Frame.**—I have a lean-to frame which faces the south, but is shaded by the adjoining buildings the greater part of the day. It is about 5 ft. by 3 ft.; and about 4½ ft. high at the back and 1 ft. in front. I should like to know the best use I could put this to. I have a greenhouse, and thought the frame might do for sowing seeds in, but fear it is not warm enough.—BEGINNER.

1844.—**Making a Kiln.**—Can any one inform me the simplest way of making a kiln to burn lime-stones picked off the fields, to be used as a manure for bog land, using turf as fuel?—A CONSTANT READER.

1845.—**Guano.**—Can any of your readers recommend from experience what quantity of guano to a gallon of water should be used for Ferns and other choice plants?—L. H.

1846.—**Climbers for Greenhouse Wall.**—Would some reader tell me what plants would do best for this purpose? The wall is rather damp, and has a flue running along its base.—G. W.

1847.—**Sea Sand for Plants.**—Has any reader tried sea sand for striking cuttings in? If so, would they kindly report results, as it would, in many localities, be easier to obtain than silver sand, and less expensive?—G. E.

1848.—**Striking Ferns, Oleanders, and Myrtles.**—I have endeavoured to strike some cuttings of Oleanders and Ficus elastica in a frame heated upon a similar principle to that advocated in GARDENING for hotbed frames (No. 1518). At the end of twenty-three days I turned out the pots to examine the bulbs, with the result that ten cuttings have rotted, and the eleventh remaining one has not shot a fibre, though still sound. Can any one suggest the cause, or direct me to success for raising these, and also Myrtles?—FILICES.

1849.—**Bronze and Golden-leaved Pelargoniums.**—Which is the best variety of bronze Pelargonium? also a good golden self, of spreading, low habit, for bedding?—GANG FORWARD.

1850.—**Wireworm in Beds.**—How can I get rid of wireworms in beds?—GANG FORWARD.

1851.—**Pot Roses in Cold Greenhouses.**—Will some experienced reader of GARDENING kindly instruct me on the culture of Roses in pots in an unheated greenhouse?—F. B. T.

1852.—**Carnations and Hares and Rabbits.**—I have about three dozen good Carnations, which are every winter bitten down by hares and rabbits. How can I protect them?—M. L. B.

1853.—**Drying off Orchids.**—Having just begun to attempt growing a few cool greenhouse Orchids, I have bought, amongst other things, a good healthy plant of Oncidium tigrinum. It is not mentioned in Britten & Gower's "Orchids for Amateurs," and I should be glad to learn when it flowers, and, at what time, if at all, it ought to be dried off. The books I have been able to meet with on this subject are, as usual, not elementary enough; and I cannot find anywhere a plain rule to indicate at what time to begin drying off those Orchids which require it; or any rule at all by which to know when the dry treatment should be stopped.—C. V. A.

1854.—**Plants not Injured by Gas.**—I have a large room with glass roof, heated by steam pipes, in which at night I burn gas. What plants will best thrive in such a room?—B. GODDARD.

1855.—**Cultivation of Freesias.**—I should be glad to learn what soil and treatment are suitable for Freesia Leichtliniana, and F. refracta alba. I planted the bulbs in pots some time ago, and they are just beginning to come up.—C. V. A.

1856.—**Lilium Giganteum from Seed.**—I have had some seeds of Lilium giganteum; when should they sown, in what sort of mould and what heat, and what should the after treatment be? I should also be glad to know within what time they may be expected to germinate.—SOUTH HILL.

1857.—**Street Sweepings for Mushrooms.**—I am given to understand that this is good stuff to grow Mushrooms in; will some one kindly detail their experience of it?—W. G.

1858.—**Plants for Fowls.**—I am aware that the sunflower yields seeds which are relished by fowls. Can anyone suggest any other plant which will yield the same results?—F. A.

1859.—**Leather Shavings as Manure.**—Can I use leather parings as manure, and how must I apply them?—BI.

1860.—**Woodlice in Melon Frames and in Mushroom Houses.**—Will any one tell me the best way to get rid of these pests?—E. O.

1861.—**Propagating Hollies and Laurels.**—I want to increase my stock of Hollies and Laurels, both plain-leaved and variegated; would any one inform me the best way and time to do so?—J. D. H. K.

HOME PETS.

Canaries Breeding.—"Lancashire" asks, a question the answer to which would easily fill a whole number of GARDENING, but I will endeavour to satisfy him in the more important points. The canaries when they are noticed to pair (that is, when the cock feeds the hen) should be fed on eggs (hard boiled), which should be pressed through a piece of perforated zinc or a hair sieve. The yolk only should be given. A supply of green food should also be given. Remember that egg is binding and green food scouring, so be careful to avoid extremes either way. Be careful to have a healthy pair of birds, and if either should exhibit any signs of indisposition, do not fail to administer a dose of Finchine, which should always be kept by all fanciers either of British or foreign cage birds; it is invaluable. The materials for nesting should consist of any soft material, but I prefer white wadding, which can be had for about fourpence per yard. The hen sits thirteen days; the young ones open their eyes when about a week old, and, if strong and healthy, are able to leave the nest at about three weeks old. Give plenty of food as before mentioned, but do not let the egg or green food get sour, as this will kill the young ones. Seeds: Canary, Hemp, Rape, Millet, and Maw.—A. D'A.

Canary with Rough Plumage.—The feathers of my bird are very rough, the wings droop, and it has not sung for more than a week, although not moulting. It has grown too fat, eats ravenously, and is very restless. I feed it on canary seed, and give it hemp once a week. The bird is two years old, and has always been healthy, and sung well till lately. Shall be very glad if any one can tell me what ails it, or what is the proper thing to give it.—TILLY SLOWBOY.

Bird Lice.—Do canaries suffer from these insects, and is Keating's insect powder considered a good thing to shake into their feathers and about the cage?—TILLY SLOWBOY.

Feathers Coming off Canaries.—Will some one say from what cause the feathers of canaries come off in patches, leaving bald places, and what can be done to remedy it?—J. G.

Parrots Losing their Feathers.—My parrot, which has been suffering from moples and losing its feathers, and been in general ill-health, has been much benefited by dried chillies; about six a day. I have so frequently seen enquiries on this subject in GARDENING that I thought some reader might be glad to know of this remedy.—M. J. S.

THE HOUSEHOLD.

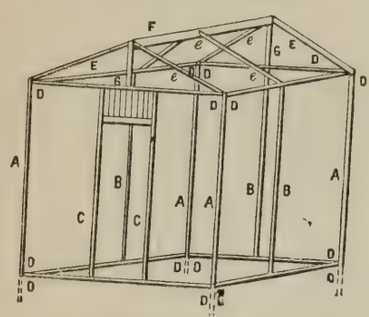
Cooking Cabbage.—Permit me to dissent altogether from the writer in last week's GARDENING, who advocates steaming Cabbage. The cooking of this vegetable may seem scarcely worthy of attention by some persons, but it really is an important matter; and it is generally cooked badly in London restaurants. How anybody who has thought of the matter can suppose that steaming would suit Cabbage is beyond me altogether, inasmuch as the extraction of some of the not very pleasant component parts of the Cabbage by abundance of water is essential to its proper cooking. I have seen steamed Cabbage, but I should not like to see it again.—B.

STUFFED CABBAGE.—For this dish we must choose small or medium-sized Cabbages. Take off their outer leaves, cut them in two, take out the heart and blanch them. Take sufficient sausage meat, thicken it with yolk of egg beaten up and beef marrow. Fill the cavity of the Cabbages and as many of the interstices between the leaves as possible with the forcemeat, tying up the whole with string. Place them in a stewpan with saveloy or Frankfort sausage with Onions, Carrots, a Clove or two, mace, pepper, and salt to taste. Pour stock over the whole, cover the Cabbages with good slices of fat bacon, and allow the whole to simmer for half-an-hour or longer according to their size. When done take off the bacon, undo the thread, and serve in their own liquor.

POULTRY.

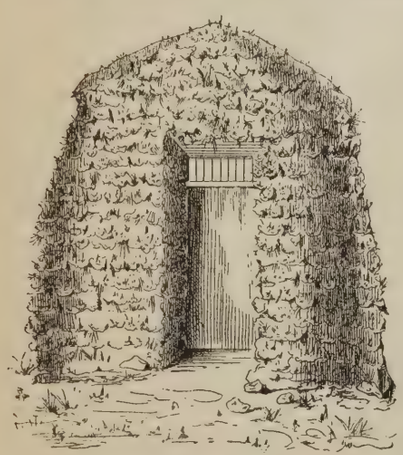
A THIEF-PROOF FOWL HOUSE.

STRICTLY speaking, it is very difficult to build a thief-proof house of any description, but with fowl-houses it is different. Where poultry keepers lose their stock it is generally because they take little, if any, care to secure their birds against



Section of Fowl House.

the visits of tramps and persons of that class, who pay no respect to the difference between *meum* and *tuum*. The fowl stealer will not run any great risk, for if caught and any previous conviction is proved against him his punishment is severe; so, unless he can get the birds easily and without much trouble, he will try his luck elsewhere. I have just completed a fowl-house which, I think, will answer very well. Here is my *modus operandi*: I cut four pieces of quartering, 7 ft. long, 4 in. by 3 in., to form the corner post (A), which I bury in the ground 1 ft. having previously tarred or charred the end to prevent rot. Next cut five pieces 6 ft. long, 3 in. by 2 in.—three for intermediate supports (B) and two for door-posts (C), eight pieces 6 ft., 3 in. by 2 in., to mortice into corner posts, top and bottom (D); the rafters for roof (E) are of 1½ in. by 2½ in. stuff, keeping narrow side up. The length will depend



Fowl House completed.

upon the pitch given to the roof, 18 in. or even 15 in. in 3 ft. will be sufficient to ensure the wet running off. The top plate (F) is 3½ in. by 2in. but must be placed on edge the same as the rafters, as much greater strength will be given to the roof this way; the supports (G) will keep the top plate steady. Now proceed to cover all round, and roof in with feather-edged boards, commencing at the bottom and finishing at the top; the same with the roof, taking care to bring the first feather-edged board over the sides a little, to form an eave, which will prevent the wet getting in should the outer roof become at all damaged at any time. When it is completed, two holes must be cut, one in each side of the roof, to form windows to admit the light; they need only be 4 in. wide by 12 in. long, and cut down the slope the same way as the rafters run. The door I make in three thicknesses of 1 in. each; in the two outside ones the boards are placed perpendicularly, and the inside or middle one horizontally; these are then screwed together and fitted into the doorway. The aperture above the door can either be of bars, as in the plan, or an iron grating; either will do for ventilation. The house is now complete as far as woodwork goes; for to enter into a description of hatching-boxes, nests, perches, &c., would occupy too much space here. This house stands upon a new piece of ground I have for gardening purposes, from which I have cut all the turf, and stacked it all round the house and over the roof, commencing 3 ft. wide at the bottom, gradually decreasing to about 18 in. at the top. In making the wall, when I have built the turves four or five high I drive some pegs pointed at one end, 12 in. long and 1 in. square, through the turves into the ground, each peg 18 in. apart only, every way. When five more turves higher are built up, I peg them on to the last row, and so on to the top; in this manner the wall will be one solid piece, and, if properly built, cannot be pulled down without the aid of pickaxe and shovel, and then only with considerable labour. The roof is covered in the same way (leaving an opening for the roof windows) to the depth of 12 in. to 15 in.; and after beating with a flat piece of wood to make it level and firm, I run some heated coal-tar mixed with fine sand over it to make it waterproof. To prevent the wet getting in at the roof windows, place a piece of glass in a frame over each opening, and by exercising a little ingenuity these windows may be made to open and ventilate the house.

This description of structure will answer two purposes—that of keeping the birds warm in the winter (a most important consideration where a supply of eggs is desired in severe weather), and providing them with a cool roosting-place in the height of summer.

H. BALL.

Gapes in Chickens.—Shut the chickens up in a coop; dust in some slaked lime (which has got cold, but not old), taking care not to let it touch the birds' eyes; keep the coop closely covered for a few minutes.—J. B. T.

Pullets not Laying.—I have not the slightest doubt that if "W. H. S." feeds the pullets with warm food in the morning, and gives them corn before going to roost, that they will lay. Four or five meals a day is too much.—C. W. A.

Fowls Pecking each other.—Can any reader suggest the cause of my fowls disagreeing. I had cross-bred Brahma pullets and a Dorking cock. As they disagreed so, I sold all but two, and bought some cross-bred Hamburgs and a Spanish cross-bred Hamburg cock. These I find disagree the same as the others. I feed them liberally, and they have a good run and are well sheltered and kept quite clean.—A GARDENER.

GARDENING ILLUSTRATED.

PROCURING THE PAPER.—The best way, in all cases where it is possible, is to obtain it through the Newsagents, Booksellers, or Railway Bookstalls. Where, however, in country districts the paper may not be obtained with regularity, it can be procured by post from the Office. All the back numbers of GARDENING are in print, and may be had through the Newsagents or direct from the Office.

SUBSCRIPTIONS BY POST.—According to the postal tariff, GARDENING can be sent through the post to any place in the United Kingdom at the following rates:—Per year, 6s. 6d.; per half-year, 3s. 3d. No subscriptions received for a less period than six months. All payments for subscriptions must be made in advance. Stamps not received for subscriptions.

Post-Office Orders should be filled up in the name of THOMAS SPANSWICK, 37, Southampton Street, Strand, London, and made payable at the King Street, Covent Garden, Money Order Office. All Letters concerning Subscriptions to be addressed to—"The Publisher, GARDENING ILLUSTRATED, 37, Southampton Street, Strand, London, W.C."

For those who can only procure the paper regularly through the post a Subscription Form is subjoined.

ANNUAL ASTERS.

SEEDSMEN offer, under the terms Victoria, Pæony-flowered, Crown-flowered or Cocardeau, Chrysanthemum, Bouquet, Emperor, Porcupine, and Quilled, some two dozen kinds of these Asters, that are largely increased in each case by several diversities of colour, so that a complete collection of all the kinds offered by any one Continental grower would probably comprise some 200 forms or hues of colour. It is scarcely possible, however, to grow all in a circumscribed space. There are several distinctive methods by which the Aster may be classed, such as comparative height, habit, character of flower, suitability for exhibition, for pot culture, or for bedding. Tall Asters comprise the fine Pæony-flowered (which we here figure), the tall Chrysanthemum, the Emperor, the tall Victoria, the Quilled, and a few others. Kinds of medium height are found in the dwarfer forms of the Victoria, the Cocardeau, the Rose, and the Porcupine; the dwarf forms comprise the short Chrysanthemums, the dwarf Pyramidal, and specially the dwarf Bouquet, which is one of the most beautiful of all for pot culture. The best bedding kinds are found in the medium-growing Victorias, the Rose, and the dwarf Chrysanthemum, as these vary from 9 in. to 12 in. in height, and form good bunches of blooms on each plant, and collectively fine masses of colour. The dwarf Bouquet kinds, whilst specially good for pot culture, are also valuable as edgings to beds of taller kinds. For pot culture for exhibition the best are the medium-growing Victorias, as these, if of a good strain, possess unequalled quality and present handsome and even heads of bloom. The distinctive forms, as found in these flowers, are those in request for exhibition purposes, as it is the custom in schedules to invite exhibits under the heads of Incurved, Reflexed, and Quilled flowers, or in some cases it is expressed as Flat-petalled and Quilled, and in others as French and German, the French including the Flat-petalled kinds, and the German the Quilled. These latter distinctions are, however, too arbitrary, and are giving place to those previously named, being more easily comprehended. The best examples of the incurved flowers are found in what is popularly known as Truffaut's Pœony-flowered Asters, formerly esteemed a grand exhibition strain, but which has given way, to some extent, to the more even and massive Victoria. An incurved flower shows all the tips of the petals converging inwards, as is seen in a Chrysanthemum, and the more solid and rotund the form of the flower, the better its prospect on an exhibition stand. All of these have flat petals, and, as a rule, have broader petals than any other kinds have. The most complete examples of solidity and perfection of form are found in the quilled varieties, as these would appear to be made rather than grown. Though not more than half the size of the flat-petalled kinds, they present a mass of quilled petals most evenly set, and in outline almost semi-circular. One is almost inclined to believe that such perfection of evenness could only be obtained by artificial means. It is, however, but the result of that constant care in seed selection which is ever the aim of the grower who prides himself in putting before the public things that are of the finest kind, and of the most meritorious quality.

LARGE PÆONY-FLOWERED ASTER.

The Cocardeau, or Crown-flowered, Asters are partly flat-petalled and partly quilled, the outer margin of the petals being of a dark red or blue, and the centre disc of pure white. These are grown more for their novelty than as presenting special decorative features. This bi-coloured form is, however, also found in some of the finest show quilled kinds, rendering them both valuable and attractive. The charming Bouquet Asters are also of a semi-quilled character, the petals being stiff and closely set. The blooms are of medium size and very compact, and most acceptable for nosegays. For this latter purpose, however, those who grow the Victoria forms will find that the later blooms that start out from the main stems are admirable, the clear bright hues and excellent forms being exceedingly effective however employed. Asters usually bloom through the months of August and September, and are therefore most fittingly described as autumn flowers. The date of blooming can, with some degree of accuracy, be secured by the time of sowing the seed, which should range from the end of March to the end of April, as may be desirable. Classed as a tender annual, although in reality fairly hardy in the autumn, it is necessary to sow the seeds under glass; and if a gentle warmth can be given to assist the germination of such as may be imperfectly matured or are rather aged, so much the better. Sown in pots, pans, or shallow boxes, in fine sandy soil, in any frame or cool house, at any time in the month of April, good seed should germinate freely; and it is

most necessary, to ensure a robust blooming plant, that the young seedlings should be pricked out into a frame or other sheltered place as early as it is safe to do so, that the plants may get strong and stout before being placed in their blooming quarters. Asters like rich soil; they are, in fact, like the Balsam, gross feeders, and prefer both manure and moisture. A rich soil induces robust leafage and rapid root action, and when so excited, the flower-stalk is not so soon developed. If properly treated, the Aster should always be well established in its positions before the upward direction of the stem of the plant is developed.

Asters make fine bedding masses, and admirably succeed some of the late spring-flowering plants that bloom freely until midsummer. When too late for ordinary bedding plants a good body of Asters, removed with balls of soil from the bed where first pricked into, and well soaked with water, soon makes a fine mass of colour, and such a brilliant and varied display of bloom is produced as scarcely any other bedding plant can give. Although it is a common rule to write of some kinds as best adapted for pot culture, yet it is by no means a good plan to give to any pot culture, as the Aster lifts even when in full bloom better, perhaps, than any other annual. Given the size of pot to be filled, and three or six plants may be lifted from the open ground with small balls of soil and be packed in as close as possible together in the pot, the soil fixed firmly around them; let the plants stand for a short time in a shady place, and not a bloom will hang its head or a plant flag, and once established these will continue fresh and beautiful for several weeks. Six good plants, with some five or six expanded flowers on each, packed into a 10-in. pot, form grand bunches for the verandah or corridor, or indeed for any situation where not too much exposed to heat or wind; whilst from nine to twelve plants of the beautiful Bouquet Aster may be planted thickly in pans or vases. These latter, grown in any fashion, are so very neat and effective that no garden should be without them in the late summer months.

The cultivation of the Aster for exhibition purposes renders more than average care and attention necessary. The soil should be deeply and heavily manured, the plants strong, robust, and free from all aphis or other insects; water freely during the hot months of July and August, and especially at blooming time if drought prevails. The plants should be placed in lines at sufficient width apart to enable the required attention in the shape of watering, mulching, tying up to sticks, thinning, shading, &c., to be given. Each stem should have its separate support, as it is of the first importance to keep the blooms from damaging each other. The centre bloom should at all times be removed, as this is invariably coarse, and a strong plant not allowed to carry more than five flowers; four perhaps would be better. A week before the blooms are required for show, temporary shades, made of card, linen, or similar material, should be placed over the blooms, as the desired purity and freshness of colour depends much upon the exclusion of the sun's rays or heavy rains for several days before the time of cutting. Asters may be set up on green-painted, sloping boxes, in lines of three or four deep, as may be desired. Neat circular pieces of white paper—sometimes these have ornamental edgings—should be used to back up each bloom, as these undoubtedly lend a certain air of elegance and refinement to the group of flowers. Exhibition blooms should show

Quilled Aster.

good size, fine form, full centres, solidity of petals, and variety of colour. The saving of good seed by home growers is not a matter of difficulty; indeed, it is not that Continental growers excel us in quality but in quantity, as it is too frequently the case that we get heavy rains just about the blooming time. As the massive double

Pyramidal Aster.

flowers absorb much moisture, it is difficult during dull weather to expel this until too late to save the flower from rot or decay. Seed that will reproduce blooms of the finest quality may be saved here—and indeed is saved, as all our finest Quilled Asters are the products of home-saved seed. Experience has shown that, because of the lesser quantity of petal with which the Quilled Aster is loaded, the seed is much more freely produced by them than with the Victorias or other fine flat-petalled strains. The blooms should be thinned and seed saved from the best flowers only, and should not be cut until the seeds are showing signs of ripeness; then laid out to fully dry on sheets of paper. They may soon be cleaned out, and the seed extracted and stored. Asters, as a rule, sport but little, this element being most found in the bicoloured flowers. A. D.

CHILDREN'S FLOWER SHOWS.

A BETTER idea than the institution of a Childrens' Flower Show could scarcely be imagined; and as spring is just upon us, it is well that little folks should be acquainted with the intentions of its promoters. Many exhibitions are held towards the end of July or commencement of August, which time of the year seems most suited; therefore it is necessary for children who delight in growing and gathering the flowers to know early, in order that time may be given for them to devote all spare moments in cultivating their plants, and will also afford opportunity for those who might wish to show their ingenuity in making floral devices or models to plan out their ideas. By adopting this important method there will undoubtedly be far more entries than would be the case were the matter delayed.

The first and foremost part of the business is for a dozen or more friends to meet and organise the affair, pledge their support, and circulate their intentions by small bills, inviting children to do their best to make the show as attractive as possible by bringing both garden and wild flowers, Ferns, collections of Grasses, floral devices, models (floral or otherwise), and offer prizes, which should consist of good books, ornamental and useful articles, &c., which would be appreciated equally as much as money, and probably do more good, and be valued and prized more highly. A large hall or school-room will be found quite as convenient as going to the expense of erecting booths and tents in a meadow or open space, although the latter is preferable for more extensive exhibitions.

A platform should be erected for the performance of vocal or instrumental music at intervals during the show, and which would answer the purpose of holding an entertainment (by the children, if possible) in the evening, and at which the prizes should be distributed.

Rules for exhibiting must be drawn up and printed, accompanied with a list of the different classes under which plants and flowers can be shown, making special reference to the time at which all names to be given in will close, also the hour at which exhibits will cease to be received. All plants should be under a child's care and attention at least three months before the show. The regulations should be most strictly carried out, as this will avoid all unnecessary confusion when the plants, &c., are brought. Vacant spaces could be well filled up with plants not intended for competition; and it is as well to have a table specially provided for any overplus.

The greatest difficulty is in judging. It is certainly advisable to employ a practical gardener, assisted by at least four others, for this tedious work; for tedious indeed it is, more especially at country shows, where children have every chance in this respect of getting good assortments of wild flowers and Grasses. In London little else but plants and cut garden flowers are obtainable; consequently, the difficulties in judging are more easily overcome.

Some consider that a flower show is hardly complete without an entertainment of some kind to wind up the day. By all means have it if possible, and let the children perform by giving readings and recitations, interspersed with music and singing. The charges of admission I would suggest in the following way:—From 12 to 2 o'clock, 2s.; 2 to 3, 1s.; and from 3 to 5, 6d; or the prices may be modified according to circumstances. Visitors holding 2s. tickets should be entitled to a front seat at the entertainment free; those with 1s. tickets to a second seat; and those who pay 6d. be charged again, as the committee of management think best. Should the show close at 5, and the entertain-

ment commence at 8 o'clock, there would be ample time to have the whole of the plants and flowers taken away if found necessary, in order to give room. The entire success greatly depends on favourable weather and the number of visitors, as even a children's flower show cannot be held without involving considerable expense. But such an institution should command the patronage and encouragement of everybody, and thereby be a means of promoting in the minds of children a greater interest in the growth of plants and flowers. NEWT.

FRUIT.

HOW TO GROW VINES ON THE LONG-ROD SYSTEM.

THE main points of this system are very simple, viz., grow the young rods this year and continue to do so every spring from the lowest bud. These will bear next year at every joint a bunch of Grapes. In autumn the (then two years old) wood which has carried the crop is clean cut out at the bottom, leaving during the winter only the young rods which have been grown during the present season. In these few words the whole system is embodied. To explain the management, I give the treatment suitable for a greenhouse, Vinery, or open walls. I grow all on this plan:—Two houses, one 60 ft. and one 30 ft. long; I refer to the latter. The Vinery—30 ft. long, 16 ft. rafters—is planted with one Black Hamburgh and one Frankenthal, each occupying one-half the house. Each carries six young rods every year, all of which always reach to the top of the 16-ft. long rafters by the end of May or June, when the young wood will be formed and has time to ripen during the whole of summer, which it does up to the top. The laterals or side shoots are never stopped at all. Remember this—it sounds ridiculous to many—at every eye of the rod, at the foot of the lateral, a bud will form, like a filbert almost in size, which must become a fruit bud next year if the laterals have not been interfered with. If they are stopped, this sleeping bud of this year would start to grow into a leaf bud at once, and no crop could be expected next year, When the leaves have fallen, in December, cut all laterals clean off, leaving only bare rods of this year's wood, which, as the season comes round in March, every bud (like a filbert) will break and will be quite certain to be a fruit bud, and will bear a bunch of Grapes. These bare young rods, each about 16 ft. long, grown in one season, and six of them are neatly tied 2½ ft. apart, and between each one of these the young shoots which are to grow this spring are trained up. By midsummer the greenhouse roof is densely crowded with foliage. One would almost be inclined to say "too much;" but not so: the more shade the better grown and coloured are the Grapes. The bare rods of last year's growth are all allowed to break, and their shoots are all stopped two leaves beyond the bunch of Grapes, and all and every succeeding lateral growth is totally stopped as soon as it appears: but only on these old bearing rods which are all bodily cut out at the lowest part in autumn. To induce a strong growth for the intended this year's rods, it is advisable to grow them already a season earlier, and cut them back to a low bud in winter, as a cut-back shoot always grows away far better than a fresh started bud, the sap flowing then already in its proper channel. Thus the bearing wood, cut down to the last eye, starts with a strong push, and forms again the new shoot for the following season. On each of my Vines (six bearing rods of 16 ft. each) I always have a show of above 250 bunches of Grapes in bloom in spring. Of course they are not so large and heavy in autumn (when ripe) as on the spur system; but I can carry double the quantity in regard to weight, and with a judicious thinning out to about fifty to eighty bunches left on each Vine, each weighing from ¾ lb. to 1 lb., I have as large berries, as well grown, coloured and ripened early in September as any of my neighbours; but the bunches are not so large as on the English spur system.

My Vines have stood this simple treatment for twelve years, and are all the better for it, without additional root-pruning or assistance. I give abundance of ventilation after June until the end of September, both front and back all night and day, assisting with a moist atmosphere, syringing every evening until the Grapes begin to colour; they are then kept without dampness touching them, but continue moistening the floor of the house, which, with plenty of ventilation, will keep the foliage in perfect health and all insects down. I never have red spider or scale, nor old wood in the Vinery.

I conclude these remarks by advising all to grow young wood this year for sure crop to follow the next season; and if variety is wanted, I have grafted many kinds on the above-mentioned Vines to grow if a satisfaction; or if not, to be cut out again after the trial given them. My wires are run horizontal, instead of the English longitudinal way, which suits better. This system, to grow Vines, and Grapes too, is the one adopted in most of our German vineyards. J. G. K.

Yorkshire.

Mildew on Vines.—A damp stagnant atmosphere favours the development of mildew, which often attacks Vines in all stages of growth. On Vines planted out it appears on the wood, on the foliage, and on the berries. It generally seizes on the leaves first, and looks like a small speck of mould, similar to that which appears on decayed fruit. These specks very soon multiply in number and increase in size, until the entire leaf is speckled. Before the disease has reached this stage the berries are generally affected as well, and in much the same way. It may be rubbed off them with the hand, but not before the damage is done. The part soon shows signs of a small brown spot and decays. When mildew extends to the wood, it remains on it until it is matured, and when ripened brown the spots of a dark colour are still visible upon the affected parts. Abundance of fresh, dry, warm air will stay the progress of but not eradicate the disease. Liberal dustings with flowers of sulphur are the most effectual remedy, and, if applied in time, will save all. Machines are manufactured for distributing sulphur, and they do their work efficiently. Those who have not got them may use a large pepper-box with a piece of thin gauze cloth tied over the mouth. On young Vines every leaf should be dusted all over every third day until the mildew has altogether disappeared. Other Vines must be treated in a similar way. Bunches affected should have the sulphur well shaken through them. As soon as there is a certainty of its being overcome, the sulphur should all be syringed from the leaves and fruit with clean water. Traces of it generally remain, however, and any Vines affected during the time of their growth should be well washed, and afterwards painted with sulphur when the pruning and cleaning is done. If care in this respect be not taken, it may appear again next season, when the Vines are started into growth; and the consequences may then be more serious. If young Vines are propagated from wood which has been affected with mildew, it appears on them immediately they begin to grow; so that a good deal of caution is necessary wherever its presence is suspected.—J. M.

Birds in Fruit Gardens.—We put bread-crumbs every morning on the window-sill, and the birds soon find them out and come for them every day. This is supposed to take "the sharp edge" off a bird's appetite; and certainly for many years we have not had such a good fruit crop as in 1879, when we tried this plan. I have heard that the same plan has been tried elsewhere with success.—E. R.

VEGETABLES.

Labelling Kitchen Garden Crops.—I find it to be an excellent plan not only to name each variety of vegetable grown in the kitchen garden, but also to add the date of sowing or transplanting, as by referring to these dates when the crop arrives at perfection one may get many useful hints for future guidance. For instance, Cauliflowers or Broccoli we have cut from the open ground for years past with scarcely an interval or blank in the supply. But in order to do this the sorts must be well selected, the dates of sowing and transplanting must be known to a certainty, and situations to suit various soils and seasons must be selected with care, or a protracted drought in summer will cause as great a failure as a protracted frost in winter. And the same applies to all crops. Peas may come in too quickly or at too long intervals apart, even if sown at what was supposed to be the most favourable date for ensuring a constant supply; and if we have no trustworthy reference to depend on we cannot correct the error in succeeding operations. Celery and such crops as are liable to prematurely run to seed if sown too soon, and which we are also anxious to have fit for use as early as possible, can only be grown satisfactorily through close observation to apparently trifling details of culture, and by classifying for special purposes. The labels for all such crops should be at least 1 ft. 6 in. long and 2 in. wide, made of soft yellow deal planed quite smooth and painted white, and the name should be written in large characters with Wolff's garden pencils. Such labels defy the weather, and remain perfectly legible as long as any crop will stand in one position. Herbs, salads, and medicinal plants ordinarily grown in kitchen gardens should have the name by which they are most generally known conspicuously placed on each bed or compartment, so that it may be readily found by the most casual observer. It is only by such means that one can satisfy oneself which varie-

The Chrysanthemum-flowered Aster.

ties of vegetables are really distinct and which are not. A constant supply does not depend on the number of varieties which one may have, nor even on "complete collections," but on the best sorts in each class.—J.

Planting Asparagus.—The worst way of growing Asparagus with which I am acquainted is in the old-fashioned beds, which devour annually as much stable manure as would suffice to dress five times their extent of surface in other parts of the garden, and usually with anything but a satisfactory result. I grow single plants in a single row with an interval of 30 in. from plant to plant. Grown in this manner, without a second row near them, they are able to extend their roots as far as they like on either side. I was induced to try this method three years ago, from having noticed for the last few years a single plant which had come up self-sown near the branches of an old espalier Apple tree. This plant has never been dressed with manure of any sort, and I have observed that what was cut from it was always finer than the average produce of the beds. I took the hint offered me by this intruder, and have profited by it. My single row produced largely last year, and now it has received for the first time a top-dressing of manure. Along one side of the row there runs a wide path, and on the other is an ordinary kitchen garden border, and all that we have to attend to is not to dig or crop too near the row. An occasional dressing of salt, or soot and salt mixed, and rarely one of stable litter, will probably be quite sufficient to maintain the plants in full vigour for several years; but by growing them on this system we can change our ground as often as we like, and plant in other parts of the garden new rows when we think it is time for any of the old ones to be uprooted and destroyed. There are probably few plants that require root-room more than does the Asparagus; hence the impropriety of crowding it in beds, where, owing to the seedlings which are continually being produced, it has often to struggle even for existence. I have just put in a row of plants, one-year-old, which were raised here from seed.—B. S.

Dwarf Kidney and Scarlet Runner Beans.—The dwarf Kidney Bean is one of the most useful vegetables grown as an outdoor crop, and it is also most accommodating if cultivated under glass. It is very impatient of cold, and therefore a warm sheltered situation should be chosen for it. Crops of it are often damaged by being sown too soon; the second week in May is a good time to sow the first crop, and a second sowing at the end of May will furnish a supply till Scarlet Runners come in, after which the Dwarf Beans are seldom asked for. The latter should have 2 ft. between the rows, and 10 in. in the row, and the tall growers 2 ft. 6 in. row from row, and 1 ft. apart in the row; they like a good, rich soil that has been well manured for a previous crop, which is better than rank manure, in which the plants are apt to run too much to foliage instead of fruitfulness. In very hot weather they enjoy a good damping over the foliage about five o'clock in the evening through a fine-rosed watering pot or garden engine. Such treatment strengthens the plants and prolongs the gatherings; it also obviates attacks from red spider, to which they are liable. For the first sowing Early Prolific is an excellent cropper and comes in early, and Pale Dun is a good kind for a general crop, with Canadian Wonder for large pods. Runner Beans require similar treatment to the Dwarf kinds, with the exception of the distance between the rows, which should be 4 ft. apart and 1 ft. in the row. They can be grown with sticks in the same way as Peas, pinching out the points when they reach the top, or they may be run up strings. They are a very valuable crop for both the amateur and the cottager. They do not take up much room, and they can be run on strings against boards or a building, on which the old Scarlet, which is one of the best for general cropping, has, when in flower, a fine appearance. Even in some of the most confined town gardens may often be seen Scarlet Runners flowering profusely and bearing pods in abundance.—S. W.

Growing Peas in Trenches.—As a precaution against drought in the case of mid-season crops, I consider this a decidedly beneficial and satisfactory mode of growing Peas. Our crops of Peas treated in this way have always been excellent. The trenches were prepared as for single rows of Celery, about 6 ft. apart, with a good quantity of old Mushroom-bed manure forked into them, and as soon as the Peas were up and staked, a good mulching of half-decayed manure was applied, by means of which one good soaking of water kept the soil moist for a considerable period. Thus managed, tall sorts, such as British Queen, Ne Plus Ultra, and Champion of England, continued to furnish successional gatherings quite as long as we have had them in more favourable seasons when grown on level ground. In the case of Scarlet Runners, Cauliflowers, and similar crops, some portion of the crops should also be planted in trenches as a precaution against drought.—H.

House and Window Gardening.

Woodwardia radicans.—This is one of the best of Ferns for growing in light airy, but not necessarily sunny windows, especially as a centre-piece for a vase, or for placing on a pedestal, as seen in our illustration. Its fronds being broad and gracefully-arched, it is, when grown in baskets, very pleasing. The fronds produce young plants at their extremities—a circumstance of which advantage is taken when young plants are wanted. All that is necessary is to take a frond furnished with a number of these embryo plants and to lay it on the surface of a broad seed-pan filled with peat and sand in about equal proportions. Peg down the frond

Woodwardia radicans.

quite flat on the mould, keeping the upper surface still upwards, and sprinkle a little silver sand over the whole. Do not, however, bury the frond; but, on the contrary, let the sand just nestle about the axils of the pinnæ and the base of each young bud. The whole must be kept moderately moist and the young plants will strike root. In a cool Fernery the fronds of W. radicans not unfrequently acquire a length of 8 ft. or 10 ft. Woodwardias like a loamy soil; and when confined to small pots are much benefited by frequent applications of manure water, or a top-dressing of some good artificial manure—such as Clay's or Standen's.

Ferns for Rooms.—Two good Ferns for cultivation in sitting-rooms are the common Sea Spleenwort (Asplenium marinum), and Polystychium capense. The stouter texture of the fronds enable them to be easily washed and to bear the somewhat rougher treatment that such plants usually get. The latter is a very rapid grower, but does not care for very much water.—C.

Primula purpurea as a Table Plant at Night.—A few evenings ago I introduced this beautiful hardy Primula to the table after the gas was lighted, and the effect was most striking, for the clear mauve-purple of the blossoms, so perceptible by day, appeared at night to be of a charming pink hue. A plant with the leaves pretty well developed, and having five or six flower-stems, is by no means an ungainly object on the table. There is a tendency now-a-days to make certain plants, such as Palms, Crotons, Ferns, Dracænas, &c., the regulation plants for the table, and any departure from these is regarded as a breach of good taste. But there is no reason why any charming plan should not be utilised for the purpose; and confidently commend to the notice of plant cultivators the subject that heads this note.—D.

The Smilax as a Window Plant.—The Myrsiphyllum asparagoides, commonly known as Smilax, is one of the prettiest climbing plants with which I am acquainted. There are no large and showy leaves or gaudy-coloured flowers to attract attention, but everything about the plant, from its long, slender, Grass-like stem to its small, delicate, fragrant, white flowers, is the very perfection of grace and neatness. The roots, being small, require but little pot room or soil, and the vines shoot up rapidly, clinging to any slight support given in the form of twine, wire, or trellis. Plants are easily produced from seed, or they can be had of any good nurseryman. I do not think the merits of this neat little climbing plant are as fully appreciated as they deserve by those who take delight in cultivating window plants, as it is especially adapted to this purpose. While a majority of plants of a similar habit become large, coarse, and cumbersome when fully developed, this Smilax never reaches such a stage, but is always light and graceful, no matter how strong and vigorous the growth. It is extensively cultivated by American florists, the gentler sex being their principal customers, for Smilax enters largely into those "little nothings" which add so much to the grace and beauty of the final touches of a lady's toilet. Although the Vine of the Smilax appears to be very delicate and fragile, it is quite the reverse, for the stems are almost as tough as wire, and the leaves remain fresh without wilting a long time after the twigs are separated from the parent plant, even in a warm and dry atmosphere; hence the special adaptability to the purpose named.—E. S. F.

Management of Conservatory (1511)—A conservatory, in the strict sense of the word is a glass structure in which plants remain during their blooming period, in which case the only care required is to attend carefully to the watering and ventilation, and screen them from the hot sun, so as to prolong the flowering season as much as possible. Presuming, however, that in the present instance the plants will have to remain in the same structure the whole year through, the main point to observe will be to so arrange the inmates that each one gets the treatment best calculated to bring it to perfection. This would be a more easy matter, and more variety and better results would be obtained, were the house in two divisions—one to be devoted to Ferns and other shade and moisture-loving subjects, the other to such plants as delight in a maximum of light and air. In the first class may be placed many kinds of fine-foliaged plants—such as Aspidistra lurida variegata; Dracænas rubra, congesta, and indivisa; Palms—Chamærops Fortunei, Rhapis flabelliformis, and Corypha australis; Lycopodiums Kraussiana and helvetica; Aralias trifoliata and reticulata; Panicum variegatum and Tradescantia zebrina for hanging baskets; the beautiful flowering climbers, Lapagerias alba and rosea, for training up the roof; and the interesting and varied family of Ferns. This may be considered as a representative list, and comprises some of the most beautiful of those plants which, although requiring a certain amount of light, yet love a somewhat close and at all times moisture-laden atmosphere. It will therefore be seen that if a varied collection of plants is desired some system of grouping must be observed. In any case, even where no separate compartment exists, plants of a like nature may be now placed together, so that the admission of air may be regulated according to their respective natures. This is a point often overlooked by amateurs, but which is really the keystone of success. Provision should be made for shading in hot weather, and it would be preferable to make arrangements for shading one-half or a third of the house at will, as it will be readily seen that the amount of sun required by such flowering-plants as Geraniums, Lobelias, Lantanas, succulents, &c., is greatly in excess of that necessary for the shade-loving subjects mentioned above. The French lath blinds, as supplied by Messrs. Richardson & Co., of Darlington, are best calculated to give satisfaction, as they can be made to any required length, and do not need a roller of any kind.

In lieu of this, rush mats may be used, or that portion of the house devoted to shade-loving plants may be freely sprinkled with flour and water. All soft-wooded flowering plants that bloom during the summer months should only be screened from the hottest sun, and should get air night and day during the summer season. If there is a back wall, we would plant out Camellias to be trained to it, and would plant in the front border, or in a large box, some such climbing plant as Tacsonia Van Volxemi, Passiflora Impératrice Eugénie, and Maréchal Neil Rose. Cobea scandens variegata is also a very free-growing, pretty, and effective climber. What is really required in connection with a greenhouse is a cold frame, in which may be raised and grown along some Chinese Primulas, Cinerarias, Calceolarias, and Cyclamens for winter blooming. It is difficult to grow these plants amongst the miscellaneous contents of a greenhouse. Amongst desirable plants may be mentioned Abutilons, Paris Daisies, Azaleas, Cytisus racemosus, Habrothamnus fascicularis, Coronilla glauca, Sollya lineraris,, Rochea falcata, Echeveria retusa, Kalosanthes, Acacia armata, and Cereus flagelifiormis. These are all of easy culture, requiring plenty of light and air, and are very effective when in bloom.—J. C., *Byfleet.*

Hints on Cuttings.—When we enquire into the conditions favourable to the development of the life latent in the detached portion of a plant which we call a cutting, we find, firstly, that as plants can only absorb liquids it will be necessary that the base of the cutting should be in contact with some moist substance; but as its power of absorption and demand for nourishment is small; so must the amount of moisture and supply of food be limited. It is in order to fulfil these conditions that cuttings are placed in sand, fibrous composts, or some medium which affords moisture, thorough drainage, and that circulation of air which is necessary as well for the life and development of the parts below ground as of those above. Secondly, it will be necessary to establish a certain equilibrium between the evaporation and the absorption, for if a cutting evaporates more than it absorbs it will perish; and as evaporation is principally excited by the plant's contact with the air, it will frequently be necessary to prevent this contact or to diminish its effects. The more leaves a cutting may possess, so much the more necessary will it be to protect it from the air. The exceptions to this law are few, being found chiefly among succulent plants such as the Cactus, Opuntia, and Sedum, and a few others such as the Pelargonium. These succeed without protection from the air and even in sunny positions, whereas all the others should be protected from the direct rays of the sun. The conditions named above are practically obtained by the use of such protections as glasshouses, frames, bell-glasses, &c. Cuttings in general may be grouped under two divisions: those taken during the repose of vegetation, or without leaves; and those taken during active vegetation with leaves attached. Those in the first division will not require to be protected from the air, or at least only exceptionally, and chiefly in order to preserve tender varieties from cold. Those in the second division, excepting succulents, require protection. In order that a plant may live its absorption must be at least equal to its evaporation; and when a portion is detached, as in taking a cutting, then absorption should be greater than evaporation. This is what happens when we make use of glass coverings, and explains their frequent employment, their indispensability when the cutting is herbaceous, taken from young and tender shoots, or covered with leaves, and also how it is possible under such conditions for a leaf, or even a portion of a leaf, to live and develop roots, which leaf if exposed to the contact of dry air would almost immediately perish.—Ombu.

Simple Propagating.—Make a strong box not less than 3 ft. square, 18 in. deep; stand in any part of greenhouse or frame, fill to within 3 in. of top with fresh horse manure made firm (the firmer it is made the better); prepare a mixture of old sawdust or Cocoa-nut fibre, with plenty of sand, mixed together, fill the box to the top; in about four days it will be ready to receive any cuttings you may wish to strike. This plan is most useful for the amateur dahlia grower, as by planting the tubers in the sawdust they soon start into growth.—J. T.

TREES AND SHRUBS.

The Laurustinus in Pots or Tubs.—The Laurustinus, so long employed to ornament our gardens, both large and small, makes a pretty pot plant, and may be forced into bloom at a very early period of the year. It is useful either as a small compact plant for general decorative purposes, or large specimens may be grown in tubs, as shown in our illustration, to be introduced as required into the greenhouse, and they by no means require the lighest and best part of the structure—where they will yield, from Christmas onwards, an abundance of flowers for cutting. Any one who has a warm house may utilise the Laurustinus to great advantage, as the plants may be placed in a light shed or cold frame, from whence they may be introduced into warmer quarters. Where there are corridors and draughty places to decorate, these forced plants will be found as useful as any plant in cultivation, inasmuch as they last so long in flower, and do not show any signs of suffering when exposed to vicissitudes of temperature. It would be well if every one made a point of keeping a stock of Laurustinus in pots, as, apart from the enjoyment to be derived from them early in the year, they serve to guarantee us against exceptionally severe winters. We from time to time experience a season which cuts off a portion of the outdoor plants, and our gardens are denuded of this pretty shrub. Plants of the Laurustinus for forcing, for supplying flowers to the London markets, are generally obtained from the Continent or from nurseries in which they are largely grown for supplying the trade. They are potted in October and November, and introduced into a warm temperature, under which, with plenty of water at the roots and frequent syringing overhead, they soon open their bloom. After flowering, the plants are either plunged in beds of ashes or soil out-of-doors, or are turned out of their pots into good soil in the following autumn, when they are forced as before. A few growers, however, raise their own plants, and dispose of a quantity of them when in a small state for window decoration, &c. In this case cuttings are taken off in August and September, when the wood is becoming firm, and are inserted thickly in pits or frames, into which have been introduced a few inches in depth of sandy soil, made firm. They are kept close for a few weeks, after which air is freely admitted. By the spring they will have made good roots, and they are then transplanted into prepared beds of rich sandy soil in the open air. Here they remain for about two years, when they are lifted and potted, allowing a little room for the roots to expand. After this the pots are plunged in a sunny position, and shifted on into larger pots as may be required. Some have their stems kept clear of shoots, so as to form standards; others are allowed to grow naturally into sturdy bushes. When they have become well-established plants in 6-in., 8-in., or 9-in pots, well set with buds, they are moved into the houses in November and December, to open their flowers. By inserting a quantity of cuttings every year, a succession of good plants is kept up.

Standard Laurustinus.

Shrubs for the Seashore.—I live on the west coast of the county of Ayr, and my experience enables me to state that I would plant, next to Sea Buckthorn and Australian Pines, common Hollies; then evergreen Oak, Arbutus, Noble or Sweet Bay, and the finer evergreens, Pines, &c., all of which will live and thrive, notwithstanding the salt in the air, if they have only protection from the wind. The evergreen Oak (on a dry soil) grows with us into a splendid tree, and should be planted more extensively than it is in England. The Araucaria, Taxus, and Cypress tribe will not form specimens without shelter from the wind, although 20° of cold do no harm whatever.—D.

Flower-pot Stoves.—Some time ago I tried the plan suggested in Gardening for heating a small greenhouse by the means of two flower-pots, and at first experienced two disadvantages—namely, the breaking of the pots, and a deficiency of moisture. I, however, overcame these difficulties by having two pots made of fire-clay, exactly the same as ordinary ones; the lower one of a large size, and the upper a little smaller to fit into it, at the cost of 2s. each. I then had three iron bands put round the lowest pot, and to the top band a couple of handles fixed for the convenience of lifting, and also from the lowest one two slight bars passing under the pot to make it more secure. Then I had a tin pan made and placed on the top of the upper pot, and filled with water, the pipe forming the chimney passing through an open space in the centre of the pan. The water soon gets heated, and a nice steam is diffused throughout the house. In making the fire, care should be taken to put a few small pieces of coal at the bottom of the pot; then fill nearly up with cinders, and on the top of that light the fire with wood and a few more pieces of coal; when that is well ignited fill the remaining space with cinders. I have given this a very fair trial through some of the most severe weather, and find it will keep up a steady growing heat for sixteen or eighteen hours without any attention. It is of great importance to keep the aperture of the chimney where it fits into the pot perfectly clean, as it is apt to get choked, and impede the burning of the fire.—H. M. D. B.

Unheated Greenhouses.—I differ greatly from the writer of an article in Gardening under this heading. I therefore give my experience of an unheated greenhouse, and show how I have kept my plants. I possess a greenhouse 26 ft. by 7 ft., and during the last winter have lost only four Geraniums. I keep Primulas, show and fancy Zonal Pelargoniums, Fuchsias, Azaleas, and Cinerarias. The way I have succeeded is by the use of large sheets of "brown paper." On a frosty night I place the tenderest plants on the floor of the house, cover them with brown paper, and then cover the outsides and the roof with the same material. This plan may be laughed at in England, but in the south of Ireland we find it most efficacious. I have no heat of any kind, and just now all my plants are in fine foliage and healthy in every way. Necessarily they will be rather late, but many would not object to this. I am sheltered by high walls on north and west, and only nine miles from the sea, while the tide washes up to my garden. Perhaps this may account for same. But some nights during the winter we had 16° of frost. Brown paper is a marvellous aid to the preservation of plants.—Amateur.

Manuring Gardens.—As the days lengthen, many readers will be looking out for a good jobbing gardener, and in many cases, I have little doubt, they will fail to find him. I hope my remarks wont give offence to any gardener who may chance to read them; they are intended to apply to the men who "know how to do everything in gardening," and who find fault with everything your previous man thought proper to do. One of their great failings is to spare manure when the supply is abundant, especially if they have to wheel it very far. I have found this the case; therefore I offer a word of caution to those who have plenty of good manure to see—if possible, that it is liberally used; and be careful how you trust the pruning of your trees to such a man.—Rustic.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 5.—Sowing the following sorts of flower seeds—viz., Primulas, Cinerarias, Asters, Stocks, Mignonette, Heart's-ease, Polyanthus, and Nasturtium; potting Balsams, Petunias, and scented-leaved Pelargoniums; removing bedding plants from Vineries to colder quarters; potting Achimenes in 6-in. pots, putting sixteen plants in each pot; potting spring-struck Centaureas, Nasturtiums, Veronica Andersoni variegata, Cedronella cana, Lobelia Paxtoni, various Petunias, and Viola cornuta; shifting Caladiums, Tuberoses, Azaleas, Cytisus, and Camellias into larger pots; also pot Vines; sowing Asparagus; planting two rows of Globe Artichokes, and second pit of Melons; pricking off Marigolds, Prince's Feather, and one light of second sown Cauliflower plants; tying up late Vines; cutting all the old wood out of Deutzias so as to encourage the growth of young shoots; planting a quantity of small Ashleaf Kidney Potatoes to produce seed for next year; finishing levelling down Celery trenches for Peas; thinning fruit in Peach-houses where too thickly set; salting Asparagus beds; clearing manure from Rhubarb crowns out-of-doors; turfing blank places in lawn; digging land for Spinach, and cleaning Herb beds; putting rimmed saucers under Strawberry plants, swelling their fruit, and staking Sweet Peas in open ground; hoeing between vegetable crops, and taking litter off Vinery borders; putting Seakale seed in water to soak, in order to hasten germination.

April 6.—Sowing Dwarf Crimson and Incomparable Dwarf White Celery in a frame for the main crop; also Spinach and Radishes; potting Caladiums, Chrysanthemums, and large Camellias; putting in cuttings of Dahlias and Alternantheras; planting out a four-light pit with Melons and three manure frames with Cucumbers, and earthing up those in a more forward state; getting out trenches for two early rows of Scarlet Runner Beans; clearing off Seakale beds and getting them forked up; watering Mushroom beds with manure-water; potting Tree Mignonette, using half loam, half cow manure, and some silver-sand, and giving but a small shift at a time; sowing Altrincham and Long Orange Carrots, Champion of England and Victoria Marrow Peas, Long-pod Beans, Early Stone, and White Dutch Turnips, Red and White Celery, Seakale, Sorrel, and Green-fleshed Melons, and a row of Sweet Peas; planting Strawberries and Larkspurs; pricking out Tagetes signata and Lettuce plants; getting all established bedding plants out-of-doors; thinning earliest-sown Turnips; earthing up Cauliflowers; clearing away Winter Greens that are running to seed.

April 7.—Potting Feverfew, Penstemons, Hydrangeas, Balsams, and seedling Cyclamens; shaking out and repotting scented Pelargoniums; shifting Cissus discolor in. pots; and Fuchsias into 6-in. pots; sowing French Beans under the protection of a wall; sowing also Cabbage, Winter Greens, Lettuce, and Autumn Giant, Early London, and Walcheren Cauliflower, Sweet Basil, Marjorum, Australian and American Cress; planting Beet for seed and a good breadth of Asparagus; pricking off Asters, Picotees, Carnations, Wigandias, Salvia argentea, and Zinnias; putting Broccoli fit for use into cellars in order to prolong its season as much as possible; salting Cabbage ground; putting annuals from Vineries in sheltered spots out-of-doors; covering Asparagus beds with soil where shoots are peeping; hoeing among Strawberry plants; manuring Rose trees; sowing the following sorts of Peas, viz., Fortyfold, Giant Emerald Marrow, and Omega; also the following sorts of Broad Beans, viz., Johnson's Wonderful, Longpod, Seville Longpod, and Hardy's Pedigree, Windsor; potting Dracænas, Palms, and a few stove plants; pricking off Perilla and Golden Feverthrum; clearing the litter from early Rhubarb, putting manure on the ground, and forking it in round the plants.

April 8.—Potting Daturas in flowering pots and Sweet Peas in 12-in. ones; sowing Radishes, Malope grandiflora, Spinach, Vegetable Marrows, and Ice plants; also Cucumbers, Melons, and Gherkins; likewise Scotch and Buda Kales; transplanting earliest Celery into manure; pricking out Arabis; sowing French Beans under a south wall; potting off Alternantheras, Coleus, and Dahlias; pricking out Celery in boxes, also from boxes into frames; giving early Vinery where the bunches are thinned a good soaking of guano-water, and getting all vacant ground dug up.

April 9.—Sowing a collection of ornamental Grasses, also Mustard and Cress; pricking out Brussels Sprouts and Cauliflower plants in frames; planting out spring-sown All the Year Round and Giant White Cos Lettuce; getting all Broccoli into the store-shed as fast as it becomes fit for use; Dutch hoeing amongst Strawberries, Gooseberries, and Currants; turning over gravel walks to give them a fresh appearance. Potting blue Salvias, spring-struck Verbenas, Iresines, and young tree Carnations; potting off Cockscombs; sowing French Beans and Grass seeds; planting out all frame Violets; pricking off Perilla and Stocks; putting in cuttings of Mrs. Pollock, Goldfinch, and Cloth of Gold Pelargoniums, and placing them in heat; also Plumbago, Bouvardias, and scented Verbenas; throwing out trenches for main crop of Celery.

April 10.—Cleaning off Broccoli stumps and other vegetable refuse, and getting manure on to the ground; earthing up and sticking Peas; getting nets put over Broccoli seeds to keep them from small birds; potting off Wigandias and other fine-leaved plants for conservatory; potting off Balsams and seedling Lobelias; sowing ornamental Grasses and Gourds, Incomparable and London Colewort, Fearnought Cabbage, Couve Tronchuda, and Seakale; planting Lettuce and picking off annuals in frames; washing Gardenias to free them from scale; covering Potatoes peeping above-ground with fine soil; watering Cauliflower plants under hand-lights with sewage; getting all established bedding plants out-of-doors; also Balm.

Flower Garden.

Auriculas.—Choice named varieties of these should now be removed into the greenhouse. Many of the pips are opening, but the best pips will not open without a little heat; they will do fairly well in frames, should the weather be mild; but dull, cloudy weather, and the temperature but little above the freezing point night and day, will be productive of mischief. The air of ordinary Auricula frames is too cold and damp for the most tender flowers. Placing mats on the frames at night and removing them in the morning is also troublesome. Alpine Auriculas are much more hardy than other kinds.

Carnations and Picotees.—The weather has been comparatively favourable for plants of these that have been potted into their flowering pots and placed out-of-doors. Athough the east winds have been cold enough, there have been no heavy rains. See that the plants are quite secure, and if any of them show, by their foliage shrinking, that a wireworm is at the root, remove the plants and destroy the intruder. Now is a good time to sow seeds to produce strong flowering plants for next year. Sow in pots or pans, which may be placed either in a cold frame or on a gentle hotbed, on which the seeds will vegetate rather more freely. The frame might also be available for many other subjects, such as Asters, Stocks, Zinnias, Rhodanthes, and other half-tender annuals which may be sown at this time. See that the ground is in a friable state between rows of seedlings that are expected to bloom this year. Look for slugs and the leather-coated grub, which still does mischief if unchecked.

Dahlias.—Success in reference to these can only be attained by good treatment now. See that they are not coddled too long in heat, nor exposed to cold east winds. The soil where the plants are to be placed should be turned over in fine weather, and a reserve of suitable compost may be prepared to place round the roots at planting-out time. Supports for them should be prepared.

Gladioli.—The general collection of these may now be planted out; and of all the plants with which we have had to deal, the Gladiolus, more than any other, requires a light, deep, rich, well-prepared soil. A change of stock is essential to the production of the best flowers. Plant them from 1 ft. apart, with a little sharp white sand under and over each bulb; then fill up the drills with loam well pulverised.

Phloxes in Pots.—If the frames are wanted for more tender subjects, these may well be placed out-of-doors in a sheltered situation. See that the plants are potted at once, if not already done.

Flower Beds.—Where it is intended to form new beds for flowers or fine-foliaged plants, they should be prepared at once. The soil should be taken out to a depth of 2 ft. to 3 ft.; a layer of brick rubbish from 6 in. to 1 ft. in thickness should then be placed in the bottom and covered lightly with partly decayed manure, and filled up with a mixture of soil suitable for the plants intended to be used. Towards the middle of next month, it is probable that Hyacinths and some varieties of Tulips may require support; a method of doing this is to have stiff wires, about 15 in. length, bent round at one end to form an eye; these can be readily inserted into the ground. Pass the matting used for tying through the eye, and tie it just under the blooms, and as the stalk lengthens the wires are lifted to the required height. Such supports are much neater than small sticks, and with a little trouble the wires might be made to clasp the stems, thus dispensing with the tying. Seeds of annuals, such as Mignonette, Beet, Iberis. Carduus, Larkspurs, Love-lies-bleeding, Prince's Feather, Sweet Peas, Linums, &c., may now be freely sown. As the majority of annuals are short-lived as regards flowers, the best plan to adopt when a succession is desired is to sow at intervals of a fortnight—the main point tending to success being that fine seeds are not buried too deeply nor sown too thickly.

Grass should be thoroughly freed of weeds, the growth of which will soon be rapid; roll and mow frequently. Also roll and weed roads and paths as often as may be necessary; tar-paved walks which show signs of deterioration should be painted over with tar, and covered thickly with fine sea-shells, sand, or similar materials. This time of the year, provided the walks be dry, is preferable to the summer time for this work. The tar should be put on hot with long-handled brushes, and the shell or other materials should be spread over the surface before the tar has set or become dry.

Shrubbery.

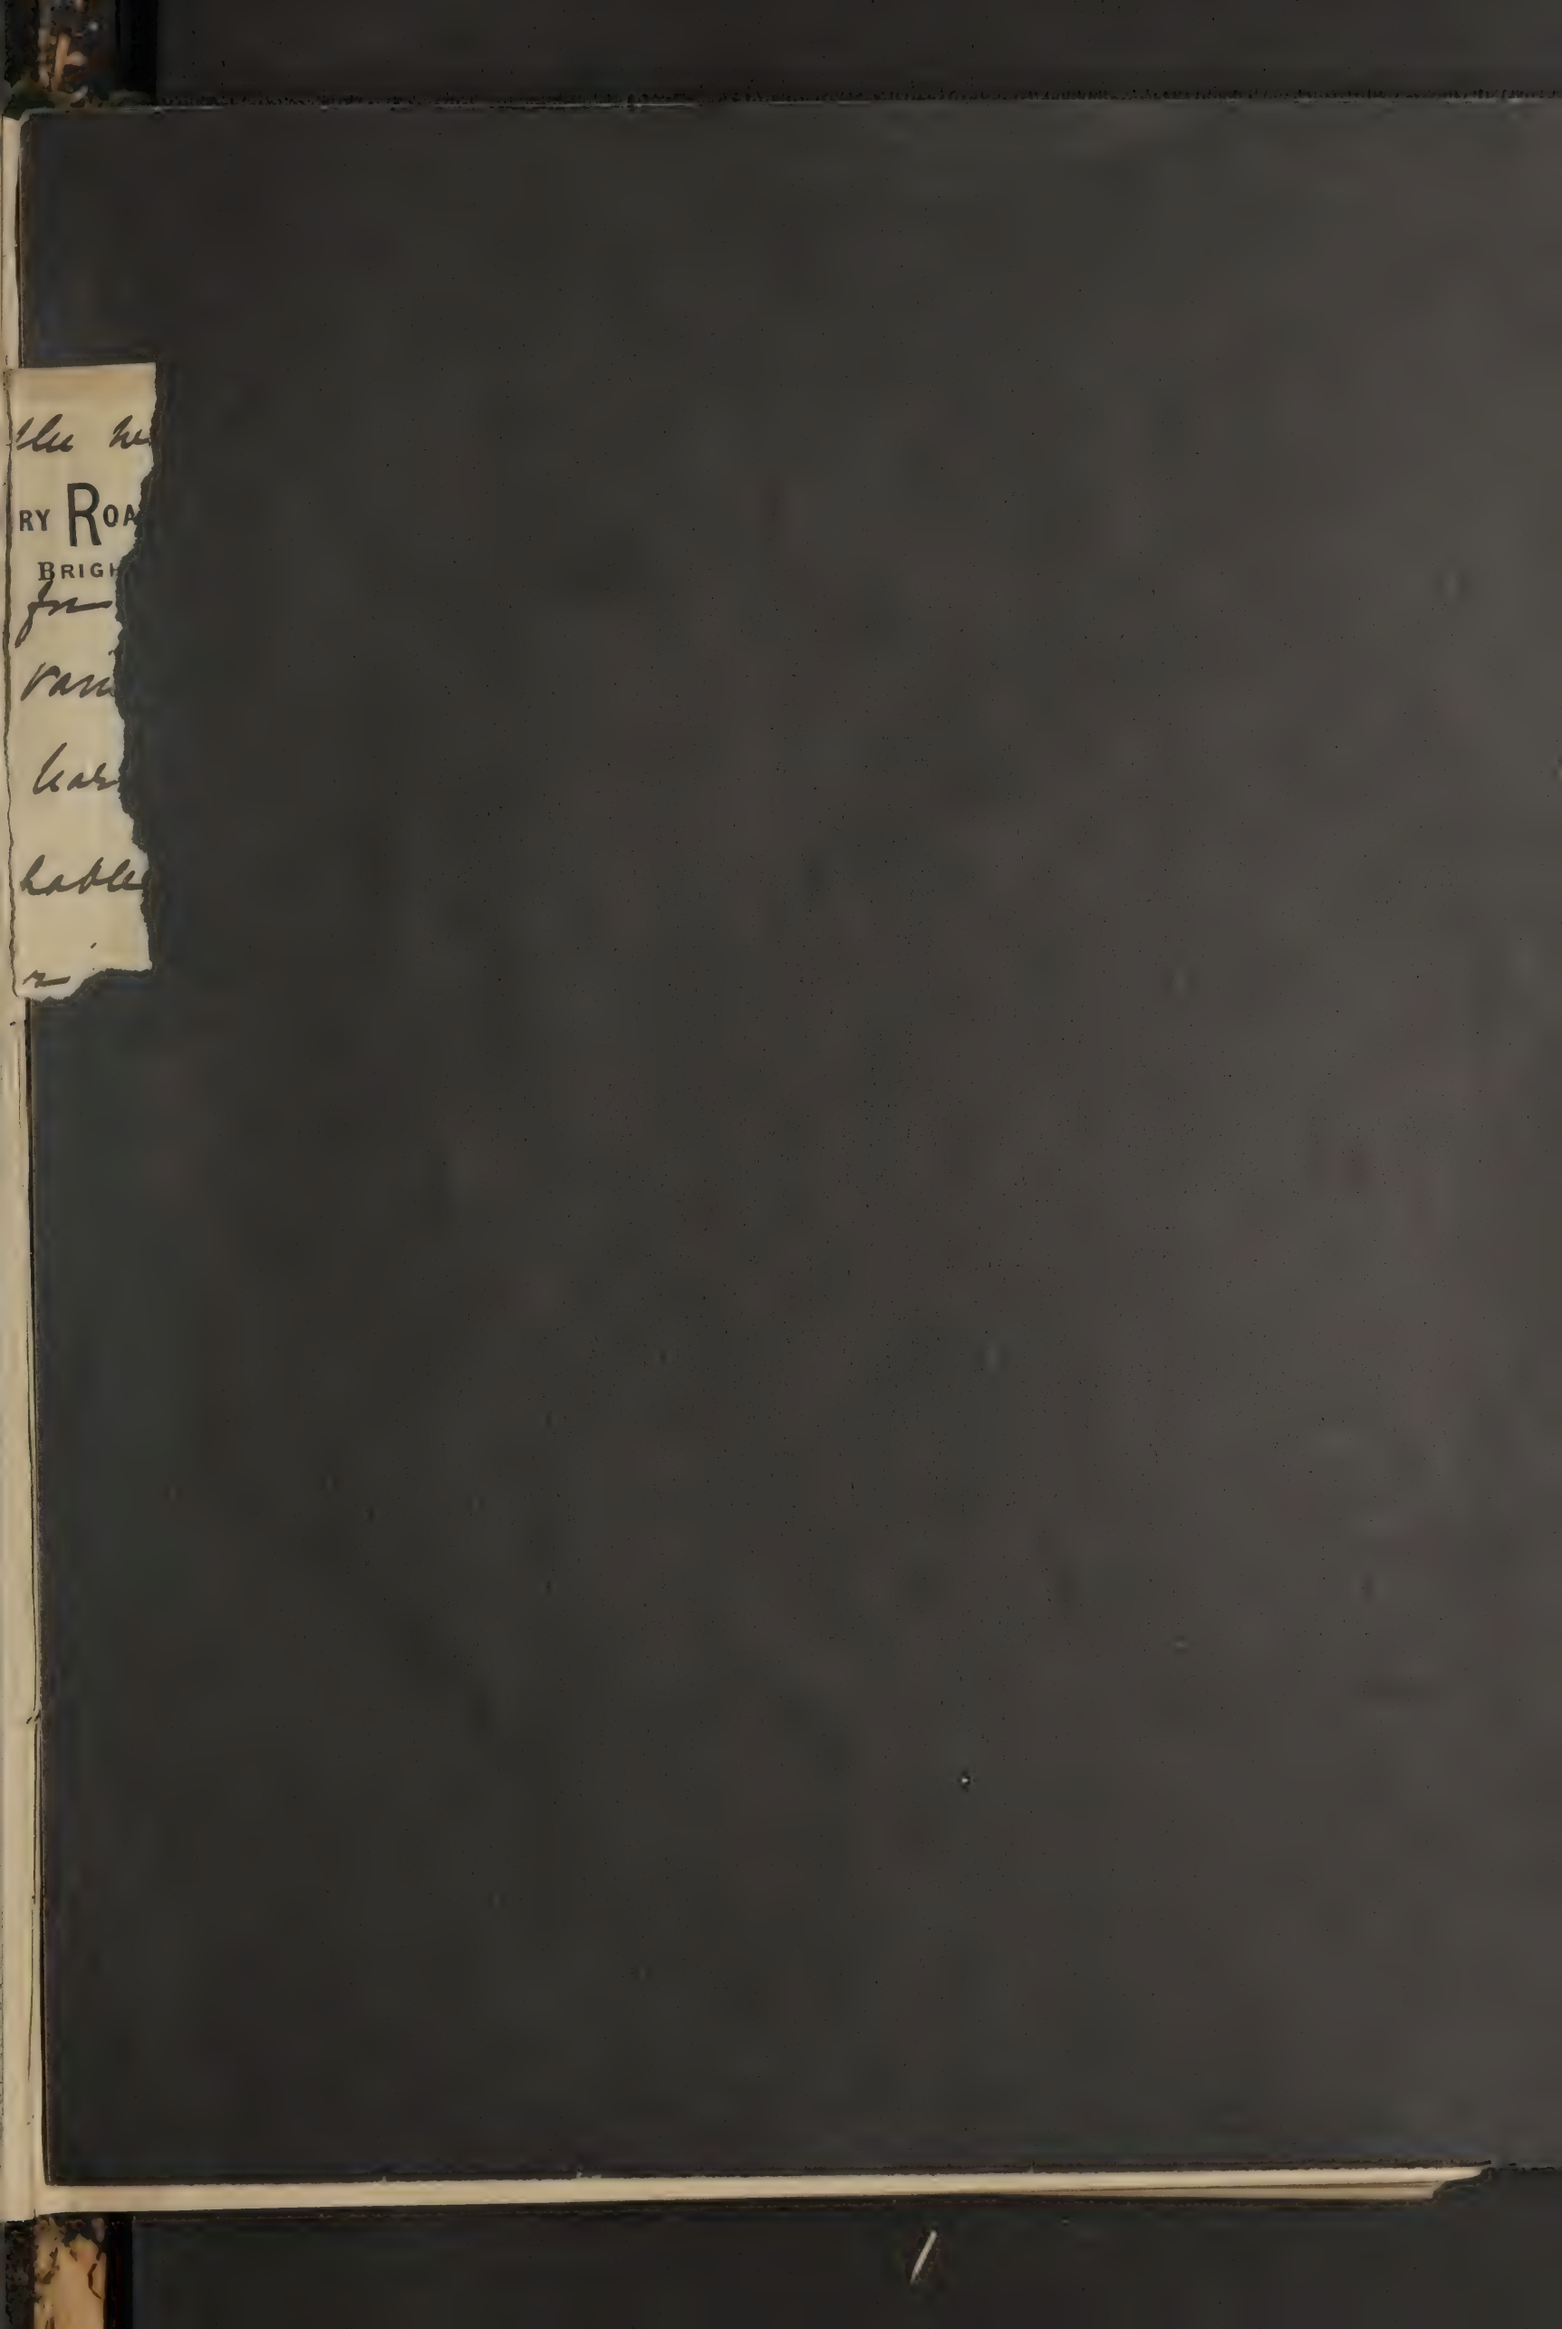
Pruning.—Where pruning is necessary in consequence of shrubs having become overgrown, or from other causes, the general character of each must be preserved as far as possible. The beauty of shrubs, and also their utility, lies very much in their individuality. Those whose habit is spreading should not be pruned to form close bushes, and *vice versâ*. The same applies to trees; and where it is necessary or desirable to prune with the object of preventing injury from high winds, my opinion is that it is much better to take out whole branches close to the stem than prune the branches themselves; this method, whilst thinning out the superabundant wood, does not destroy the character of the tree thus operated on.

Ivy and other Edgings.—These, when kept in good condition, are extremely effective, but the contrary is the case if neglected. Ivy and Euonymus radicans are useful town plants, and edgings of these, from 1 ft. to 2 ft. in width, are especially adapted for small open spaces, as, for instance, squares. The decaying shoots of each should be carefully pruned out, and all dead foliage removed. Then the best and strongest of the young wood should be retained and regularly pegged down, putting in new plants where required. A light dressing of thoroughly decayed manure will also be found very beneficial.

Fruit.

Vines.—At the present time, perhaps the most important matter connected with late Vines, which will now be starting into rapid growth, is to be certain that the borders have had a sufficiency of water to thoroughly moisten them throughout—a not very easy matter, taking into account the long time that water has had to be withholden from them, more particularly in cases where the Grapes were left to hang on the Vines; therefore, if any doubt exists as to deficiency on this score, fork down to the very bottom of the borders in one or two places that seem likely to be the driest, and if the soil on being pressed in the hand does not adhere, then water is still required. Mulch the borders thinly with stable litter, and keep up a humid temperature of 60° in the coldest weather; and whenever it is sunny give air early, and as carefully as if for early Vines, closing up by 2.30 with a renewed application of humidity, when, if 85° are reached, the Vines will revel in the extra warmth. Disbud as soon as the best bunches can be discerned, leaving two shoots on each spur in the case of old Vines, but one only in the case of young and vigorous ones. Those in flower, Muscats more particularly, demand hourly attention to secure a good "set." If a circulation of warm, dry air, to disturb the pollen, could at all times be maintained, artificial fertilisation would be best left alone; but as this is impossible (at all events, in spring, when biting easterly winds are the rule), it is best to resort to artificial aid, which should be used when the highest temperature has been attained. The removal of surplus bunches before blossoming rather than after that period would tend to ensure a better "set." Lateral growths should be left intact till after the fruit is set. Grapes that are stoning should be kept at as equable a temperature as possible—say 65° at night and 75° by day, declining proportionately in exceptionally cold weather. A moderately humid, ammonia-charged atmosphere should still be maintained, but as the Grapes approach the saccharine state, moisture should be gradually withheld. Supply pot Vines that are bearing full crops with an abundance of clear manure-water, which, as a matter of course, should be of about the same temperature as that of the soil, and, where there is space for development let the lateral growths extend without restraint.

Melons.—It is now time to sow for the principal summer crop. The seeds should be sown singly, or at most a couple, in a 3-in. pot or other, that no potting off or division be required; for, however carefully this may be done, a severe check is the result. When the early plants show fruit, select about four of the finest on each plant, and fertilise at one and the same time. Some varieties fail to swell off more than one or two fruits, and the reason frequently is because they have been set at different times, and the one that has got the lead has retained



it. Till brighter weather arrives, apply air and moisture somewhat sparingly, and also keep the bed rather dry than moist for the present.

Hardy Fruit.—The present, as far as fruit culture is concerned, is the most critical period of the whole year, for a single night's frost may do a large amount of injury; hence the importance of adopting preventive measures to ward off frost, let the cost of labour to do so be what it may. Evergreen boughs and Birch or Hazel spray, straw or hay bands, netting or canvas fixed to short poles, are all handy and effective protectors for walls that have not—as walls should have—proper movable blinds. Small bushes, lines of cordons, and espaliers can be protected in the same way as wall fruits, the labour of doing so being by no means so formidable as one might imagine. Where there are movable curtains to walls, they should be kept down during bright sunshine, to retard the opening of the blossoms in hopes that the advanced season may bring freedom from frost when the flowers are fully expanded; and, no matter what the weather may be, the coverings should be let down nightly, and on frosty mornings be allowed to remain down for some time after the sun shines, and during the prevalence of keen cast and north-easterly winds they should also be left down. A plot of ground should now be prepared on which to plant out, as soon as sufficiently hardened, the earliest forced Strawberry plants. These, if the flowers be kept picked off, will produce early runners for another season's forcing, and some varieties—notably Vicomtesse Héricart de Thury—will produce fine fruits in the autumn.

Vegetables.

The earliest Potatoes will soon be above ground, and vigilance will be required to keep the soil well drawn over them till the haulm gets too high for this being done, when stable litter or Bracken shaken lightly over them will form an efficient protection against any ordinary frost. In dry weather the hoe is a great economiser of labour, and at this early season, though the weeds are barely discernible, it should be in full swing among all growing crops, such as Spinach, Cabbage, Broccoli, Lettuces, and Parsley, when it will both aid growth and destroy weeds. In the event of showery weather a sharp look-out for slugs will be requisite, or Cauliflowers, Lettuces, and similar plants will soon disappear. The best trap for these is bran put down in small heaps, of about a tablespoonful each, near the plants, early in the morning and late at night. On this they will be found feeding, and can be destroyed. Lime, soot, and wood ashes all more or less deter them, but bran is the best remedy. It is yet rather soon to sow the general stock of Broccoli and Kales, not but what they would do best if sown now and grown on without check; but, as oftener than not they have to be planted on land that has been cropped with early Peas or Potatoes, the plants are apt to get stunted ere the ground is at liberty for them, so it is best to sow late; still, the early kinds should now be sown, and also a few Savoys and Scotch Kale. We usually sow thinly in drills 1 ft. apart, and then no transplanting, other than the final one, is required. Potatoes, Carrots, and Radishes in frames should be well aired—indeed, on bright days the lights should now be entirely off; more water will also be required, and a spindly growth of Carrots and Radishes prevented by timely thinning. French Beans in frames may be kept rather close until they begin to show flower, after which, air freely, support with Birch twigs, and water liberally; a check from want of water would be the precusor of red spider. All the Seakale intended to be forced this season should now be covered up.

Celery for Rheumatism.—There is no definite limit to the quantity of Celery that should be taken in severe cases of rheumatism or gout. Too much cannot be taken while it is digested. The cause of rheumatism and gout is a deficiency of alkalies in the blood and an excess of fibrin; both caused by flesh-eating, and consequently a deficiency of oxygen in the blood. The whole evil is certainly and completely remedied by ceasing to eat flesh at all, and eating fruit and vegetables. But Celery, of all vegetables, does the work required more effectually and rapidly, cooked for meat for dinner in milk, as detailed in pamphlet "Food for the Million," by W. G. Ward. Another way: Boil whole sticks of Celery; when soft take out, cut lengthwise in slices and dip in butter, then fry in olive-oil. It may be eaten raw as long as digestible as well. In severe cases of rheumatism it is to be drunk as well as eaten; the water Celery is boiled in, as above, to be drunk. Or a stick a day, boiled down until all is dissolved except a little stringiness; remove it, add the juice of one Lemon, and drink it. Such a thorough plan of eating and drinking Celery will remove rheumatism or gout in a month or two. Of course, no flesh should be eaten, or alcohol drunk. More, it is certain—indeed infallible—if attended to as above.—Wm. G. Ward.

CHEAP AND GOOD GREENHOUSES.

In several nurseries there are now greenhouses erected on a novel principle, the most noticable feature being the system of glazing adopted, putty being entirely dispensed with. Mr. R. Wetherall, of Whetstone, has erected in this way four span-roofed greenhouses, each 150 ft. in length, and about 18 ft. wide. The sides of the houses are about 3 ft. 6 in. in height and are of timber, stout posts being placed into the ground a short distance apart sufficiently deep to ensure the requisite firmness and strength to carry the superstructure. Oak is the best of all timber for posts; the boards should be about 1 in. or 1½ in. in thickness; they should be rabbeted together, and secured to the posts with screws, which are better than nails, because it is easier to take the structure to pieces and remove it at any time. The ventilation required for the side of the houses can be easily provided by having one of the boards hinged and so arranged that the external atmosphere will come into contact with the hot-water pipes, and thus become warmed before it is diffused into the house. This hinged board can be allowed to lift up or drop down when opened as may be preferred; an iron button will be all that is required to keep the ventilator closed when air is not wanted. When expense is not a matter to be studied, of course these lifting, or rather movable, boards can be opened and shut by the well known crank system, by which plan much time is saved in ventilating. When the sides are completed, and the posts are sawn off to the requisite height, the plate that carries the roof should be put on and also attached to the supports with screws; indeed, no nails at all should be employed, and thus the structure is always portable. The roof itself of these houses is formed of rafters of stout deal quartering placed about every 5 ft. or 6 ft. apart, with ridge piece, precisely in the same manner as that adopted for ordinary span-roofed houses intended to be fitted with sashes. When this frame-work is constructed and screwed together, lighter pieces of timber are carried lengthwise throughout the roof, at distances of about 2 ft. apart; they are all well screwed together, and rabbeted so as to form a resting place for the glass. At distances of about 18 in. a groove or notch should be cut in the cross frame-work so that no water may lodge. Give, before placing on the glass, three good coats of paint, and when dry commence to glaze; the glass used should be of the best 21-oz. quality and 24 in. square is a good and useful size for each pane. Simply lay the squares on the framework without any lap, butting the edges close together. There is no fear of drip, the rabbet in the framework prevents the glass from slipping, and it only requires security from removal by the wind to complete the operation. This is done in Mr. Wetherall's houses by a metal button working on a screw attached to the frame-work, and when the pane of glass is laid in its place by simply turning the button round and placing a little strip of felt between the glass and the metal fastening; it is then held tightly in its place, and the felt is a safeguard against danger of breakage through the expansion and contraction of the iron button. If by any chance a square becomes broken, it is easily replaced in a few seconds by simply turning the button, taking away the damaged pane and replacing it by a new one in the manner described. The ventilators for the top of the house are constructed and made to open in the usual manner. These structures when finished have a very light appearance, and plants thrive admirably in them; therefore they are adapted to the requirements of any and every garden, but for nurserymen and growers for market they are the best that can be adopted, seeing that they are cheap, effective, and, above all, the landlord cannot claim them, because they are screwed together in every part, and a tenant at the expiration of the term of occupation can remove them.

H. B.

GLASSHOUSES AND FRAMES.

White Lilac.—We have lately cut this in great quantities, and of the purest white. We dig up large bushes, 8 ft. or 9 ft. high, of the common large-flowered purple kind, with good balls, and set them in corners of early Vineries and Peach houses. A temporary box of bricks is constructed for enclosing soil round their roots. They are kept syringed and watered, like other occupants of the houses, and, with the exception of the partial shade obtained from the Vine leaves, they have had all the light that there has been. The branches have been tied up to economise space, and thus bundled together they have looked like pillars of snow. Lilac produced in this way is preferable to that grown in darkness, as the foliage is of its natural colour, and in the case of flowers, even for table decoration, there is nothing like their own foliage for garnishing.—L. P. M.

The Sensitive Plant (Mimosa pudica.)—This is an interesting little annual, which may be grown by any one possessing a warm greenhouse. The seed may be sown at once in small pots, one seed in each, filled with fine, light, sandy soil, and placed in a warm house with a bell-glass over them, or a sheet of glass. If they can be placed in a little bottom heat all the better. When well up, and the pots are getting filled with roots, put them into 5 in. pots—a size which will be plenty large enough for them—using peat, sand, and light loam. The plants must not be syringed during the day, or the leaves will close at once. A well-grown plant affords amusement by its leaves closing immediately they are touched with the finger.—S.

Sensitive Plant (Mimosa pudica).

Covering bare walls in Ferneries.—Nothing adds more to the beauties of an indoor Fernery than well-covered walls of green verdure. No matter how choice the collection of Ferns, if the walls are bare, or, as often is the case, whitewashed, the fernery looks wanting. The following simple efficient covering, therefore, will be found to give entire satisfaction. Prepare a sufficient quantity of wooden pegs, 1 in. square, 4 inches long, tapered, wedge-shaped at one end. Begin at the top row of bricks in the wall, and at intervals of 18 inches make a hole with a chisel, and put in one of the pegs, again in the fourth row of bricks, and so place pegs in the wall over. Then get some wire netting, 2-in. mesh, sufficient to cover the wall. Begin at the bottom row of pegs, and, with some wire staples sold for the purpose, fasten your first length of netting. Have ready a quantity of rough Sphagnum Moss, also some rotten turf and lumpy peat mixed well together with a good addition of sand; the Sphagnum is to be first put inside the space left between the netting and the wall, filling in the back with the above compost, so that when finished the Sphagnum alone will be visible. When finished get some little plants

of the pretty Moss Selaginella denticulata, and prick in carefully a few inches apart over the whole of the Sphagnum. You may also add at the time of filling some small plants of any of the Maiden-hair Ferns, also Pteris serrulata, P. cretica albo lineata, or other small Ferns, all of which add to the beauties of the house. When finished, an occasional syringing with a fine rose until established is all that is requisite; and, as now is the best time of year for such work, you will soon be rewarded for your labours. I may mention this covering is equally adapted for the cool or warm fernery.—J. S.

Seedling Ferns.—Few plants are more serviceable than seedling Ferns, especially the Maiden-hairs and Pteris serrulata and longifolia, all of which are easily raised from seed. Where large specimens of these Ferns are grown, seedlings are usually found springing up abundantly on all moist surfaces, as the seed-spores are so light as to be carried and deposited over the whole house. If sown in pans, or on lumps of peat, the seed must not be covered, but merely shaken on the surface, which must be kept constantly moist. The seedlings also enjoy a humid, brisk atmosphere, but when required for decorative purposes they should be gradually inured to a cool and moderately dry atmosphere, so as to harden the fronds and render them capable of withstanding the fluctuations of temperature to which they are invariably exposed. In Covent Garden, Maiden-hair Ferns are in great request for these and other purposes. They are grown in small pots for the most part alone; but sometimes mixed with Tulips and other bulbous plants. Their fronds, too, in a cut state, are so much in demand that long, span-roofed houses are wholly devoted to their growth.—H.

Deutzia gracilis.—This charming little Japanese shrub might with propriety be called everybody's plant, as it will grow and flower under almost any sort of treatment, and it can be had in bloom from Christmas to midsummer. It is one of the most useful of plants for conservatory decoration, and also for furnishing cut flowers; and the cultivator may always depend on being well rewarded for any extra care which he may bestow on its cultivation. It strikes freely from cuttings taken from the young growth and put in thumb-pots in sand and leaf-soil in a temperature of 60° or 70°. As soon as rooted, they should be potted on into 3-in. pots and replaced in heat, and as soon as the roots have reached the sides of the pots they should be shifted into 5-in. pots, using a strong fibrous loam with a little clean coarse sand at each potting, making the soil firm. Keep the plants in a good moist heat till they have made their growth, when they require a drier atmosphere in which to ripen the young wood before they are turned out-of-doors. If this be not attended to, plants of it started in November and December will be a failure, through the blooms going blind at a time when flowers are of most value. When the growth is finished and well ripened, harden the plants off by degrees, and plunge the pots up to their rims in ashes in a sheltered situation well exposed to the sun. If any of the plants require larger pots, shift them before plunging them, as they force better than when it is left till they are taken into the forcing house. Plants required to be in bloom at Christmas should be started in an atmosphere of from 55° to 60° about November 20, and a few should be introduced into heat once a fortnight where a succession is required. For late blooming set the plants behind a north wall until they are required. When they are in growth and the pots are full of roots, supply them freely with liquid manure, and when in bloom keep them cool and shade them from the sun, in order to prolong the bloom. When the flowers have faded cut out all the old wood, allowing nothing to grow but the young shoots from the bottom, and as they advance in growth draw them towards the rim of the pot, so that when in bloom the flowers will hang gracefully over the side.—J. S.

Clematis indivisa.—This is a capital greenhouse climbing plant for supplying cut flowers, and in a light, airy house with a mean temperature of 55° its sprays of snow-white, star-like blossoms, opening early in spring when flowers are scarce, are most acceptable. Its foliage, too, is dark and glossy, and free from attacks of insects.—B.

GLOXINIAS AND THEIR CULTURE.

THESE are very easy to increase, either from seed or by cuttings; they are also easily grown, and most useful for decorating the stove or intermediate-house in the summer season, continuing to bloom more or less for a considerable period; while the flowers are very useful for cutting, and if placed in water they will last for several days, provided the plants have made their growth and produced their blooms in a thoroughly light and airy situation.

In raising Gloxinias from seed, it should be sown early in the spring, so as to allow the plants an opportunity of attaining a sufficient size, in order that they may flower during the summer in a way that will exhibit their true character; if sown about the middle of March they will have the requisite time. The seed should be sown in an ordinary pan with 1 in. of drainage at the bottom, on which place a little Sphagnum; the soil should consist of equal parts of loam, peat, and leaf-soil, all sifted; add to the whole one-sixth its bulk of sand, it being essential to have the material of a loose open nature, or the roots of the young seedlings will be injured in transplanting them; fill the pan with the soil to within ½ in. of the rim, pressing it down moderately firm; then water with a fine rose, so as to close up the surface, and on this sow the seeds, not too closely, or they will become crowded

Spotted Gloxinia.

and consequently drawn up before they are large enough to pot off; cover very lightly, and place in a temperature of 65°. As soon as the young plants appear, elevate them close up to the light, screen from the midday sun, and supply them with water, giving a little air during the day. When the leaves are 1 in. long, move singly into 3-in. pots, using soil similar to that in which the seeds were sown, and at once replace them near the light, raising the temperature as the days increase in length. By the end of June they will require shifting into 4-in. pots, using the soil without sifting, and should receive the treatment previously recommended. The best kinds should be marked for propagation and the inferior ones discarded. When the flowering is over, give them less water, discontinue shading, and admit more air, so as to ripen the growth. When the leaves have died down, the soil must be allowed to become quite dry, and be kept for the winter in a temperature of 50°—cooler than this is not safe for any length of time. They generally winter the best when the bulbs are allowed to remain in the soil and pots in which they have been grown; but as they become large and are in pots of a considerable size, this is not always convenient, in which case they should be stored in paper bags filled with dry sand to preserve them from the air, otherwise they shrivel, and thereby receive serious injury.

To give a succession of flowers through the summer a portion of the plants may be started about the middle of February, and a further supply in March; let the pots be proportionate to the size of the tubers—7 in. in diameter will be large enough for the second season. In potting just leave the crowns of the tubers on a a level with the surface of the soil, and immediately they are potted place them in a temperature of 60° at night and 5° or 10° warmer by day; if not put in heat as soon as potted, the roots will rot; the soil ought to be in a slightly moist state when used, and little water should be given until growth has commenced. Treat them throughout the season as recommended for the preceding summer as to heat, shade, air, light and moisture. As already pointed out, their satisfactory flowering will depend upon their receiving abundance of light; a shelf over a path within a few inches of the roof is the best place for them, for in such a situation not only do they get the requisite amount of light, but they also receive more air, both of which are so essential to short sturdy growth. This summer they will bloom well, and increase considerably in the size of their roots, yet it it is in the third and fourth years after sowing that they will make the finest display.

When the bulbs get large they may be divided, retaining to each portion some of the buds with which the crown is furnished; but the most general method of propagation, and by far the most expeditious, is by leaf-cuttings. If the leaves be taken off in the summer when fully matured with a portion of the leaf-stalks, and this portion inserted in 5-in. pots, drained and filled with half peat, or loam and sand, with ½ in. of sand on the top, and kept in a brisk heat slightly shaded, and the soil moist, they will form healthy bulbs before autumn; or, if the variety that is to be increased be scarce, several may be produced from single leaves by cutting through the midrib on the under side in four or five places, and laying the leaves flat down on the soil in pots or pans, prepared as above, but sufficiently wide to admit of their being so placed; over each place where the midrib has been severed secure the cut parts on the soil with a pebble about the size of a cockle, at which points bulbs will be formed, which when the top has decayed in the autumn will require to be wintered, and afterwards grown on in every way as recommended for the plants raised from seed.

An Elegant Palm (Cocos Weddelliana).—Where plants are in much request for table decoration, Palms are almost indispensable; and none are more light and elegant in appearance, or so well suited in every respect for the above purposes, as Cocos Weddelliana. Unfortunately, the majority of other kinds soon get too large for table embellishment; but by keeping these confined to 6-in. or 8-in. pots, they may be preserved in perfect health for at least a couple of years, if well supplied with water at the roots, of which at most times they enjoy rather liberal supplies. Areca lutescens is a Palm of remarkably graceful habit, and comes next in order of merit to the above, and as it will stand in a cool stove or moderately warm greenhouse, it is a very desirable variety to cultivate. The yellow stems of this show in pleasing contrast with its delicately pale-coloured leaves, and give the plant a very striking appearance. There is one advantage in growing Palms for table decoration, independent of their great beauty and general suitableness for the work, and that is, they are constantly increasing in value for other purposes, such as the decoration of conservatories, halls, &c., for which no plants are more suitable or better adapted in every respect. Cocos Weddelliana, when grown into a large specimen, makes a handsome object for a warm greenhouse or stove. The best soil for it is half peat and half turfy loam, with plenty of sand added; or it will grow fairly well in any ordinary good potting mould. Plenty of moisture overhead and at the roots, and a warm temperature, are its chief requirements, and it should be placed in a rather shady position.

Destroying the Gooseberry Caterpillar.—I find the Gooseberry caterpillar one of the easiest of pests to destroy. Every time it attacks my trees I dissolve 2 oz. of white Hellebore powder in a gallon of water, and apply it with a syringe in the evening after a fine day. —CLIFTON TERRACE.

ANSWERS TO QUERIES.

173.—**Sweet-scented Plants for a Greenhouse.**—We would plant some Tea Roses to be trained up the roof, which would give a succession of fragrant flowers. Violets may be potted in autumn, and placed under cover at the commencement of the winter. Narcissi and Hyacinths also, potted in the autumn, will afford fragrance in the spring months. There is also the Lemon-scented Verbena, and Musk and Mignonette may be sown, so as to come into flower at an early period. Triteleia uniflora, if potted in September, will bloom freely in early spring. It is delicately scented, but is not suitable for cutting, owing to the strong Garlic-like odour which the stems exhale when cut. Then there are Pinks, of which any admirable varieties exist, not omitting the old Clove Pink.—J. C. B.

1743.—**Culture of Kalosanthes.**—Pot off the cuttings at once into small pots in a compost of two-thirds turfy loam and one-third leaf-mould, keeping them rather close for a time until fairly established. Stop the points of the shoots, to induce a bushy formation, and shift when necessary into 4-in. pots, placing the plants in a sunny, well-ventilated position in the greenhouse. The Kalosanthes, being of a rather succulent nature, requires a considerable amount of solar heat to mature the wood, without which the flowerheads do not form. During the early part of September the plants will be benefited by full exposure to sun and air, wintering them in a cool greenhouse, and ventilating freely during the early spring months.—J. C. B.

1563.—**Growing Mushrooms in Cellars.**—The great secret of success in Mushroom culture consists in properly preparing the manure. Horse droppings are best, but should ordinary stable manure be used it should be turned over several times until the rank steam is evaporated, at the same time rejecting the littery matter. About 1 ft. of manure will suffice for use in cellars, and the beds may be made at any time during the year—that is to say, if the cellars are so situated that a cool equable temperature can be maintained in them during the hot summer months. A bottom-heat thermometer should be placed in the beds when made, and when it marks 70° to 80° the spawn may be put in.—B.

1571.—**Greenhouse in Town.**—The best plants for "V. P.'s" greenhouse would be, for spring and summer—Geraniums; Pelargoniums, zonal, show and fancy; Cinerarias, Calceolarias, and, as a rule, the older and some of the more robust varieties of Fuchsias; also Campanulas and Balsams. Ferns would do well in such a house, but only the more robust kinds, such as Asplenium bulbiferum, &c. For the winter Chinese Primulas, Chrysanthemums, Hyacinths, Tulips, Narcissus, &c., will be found to bloom freely. Nearly all these (except the bulbs, of course, which must be purchased) may be grown from seeds or cuttings, and with care will give good result; but in anything like a large house too hard-wooded or shrubby plants, such as Azaleas, Deutzias, &c., will succeed; the blooms are poorer and scantier every year. In the way of climbers a Passion-flower is the only thing I would recommend for such a situation.—R.

1626.—**Small Gardens near Towns.**—"Amateur" does not say whether he wishes to grow vegetables or flowers; but, supposing the latter to be desired, I append a list of bedding and foliaged plants, with their colours, that will do well almost anywhere if taken care of. For flowering plants—Geraniums, all colours; Calceolarias, yellow; *Verbenas, various colours; *Petunias, ditto; *Phlox Drummondii, ditto; *Indian Pinks, ditto; *Stocks and Asters in variety; and *Lobelias, blue. Foliage plants—*Amarantus melancholicus ruber, crimson leaves, very effective; Perilla nankensis, dark bronze; *Pyrethrum (golden feather), yellow; *Cineraria maritima or candidissima, silvery. These are nearly all that will be found to do well near a large town of this class. Among taller-growing things, suitable for mixed borders, Chrysanthemums, *Dahlias, Delphiniums, Hollyhocks, and Herbaceous Lobelias (tall) are the best; also Lilies, the hardier sorts, and *Iris. Those marked with an asterisk (*) may be found to do better or in more unfavourable situations than the others. In the way of climbers, Nasturtiums and Major Convolvulus are the best; and in annuals, Mignonette, Venus's Looking-glass, and Corn-flowers.—R.

1779.—**Culture of Statice Halfordi.**—Cuttings root readily in sandy peat in a warm pit, or under a bell-glass in a warm greenhouse. When potted into single pots keep close for a time till established, then move to an airy greenhouse, shifting into larger pots when required. They will grow in good peat or in equal parts of turfy loam and peat, adding some sand and crushed charcoal to keep the soil open. The plants require a good deal of water, therefore the pots must be well drained. Pick off the first blooms that show to ensure a fine head of bloom.—E. H.

1792.—**Soot and Lime for Crops.**—In most cases I should prefer the soot without the lime. Onions will be benefited by very heavy dressing of the former, given in showery weather. A bushel to the square rod will not be too much. It is best applied in a liquid form to Peas, except in cases where birds are troublesome, in spring; then a little soot dusted over the rows will make the Peas distasteful to the birds, and act as a stimulant to the plants. At the same time, soot and salt in combination is an excellent stimulant for Wheat, about fifty bushels per acre of the former to 3 cwt. of the latter, sown broadcast in spring.—E. H.

1777.—**Cucumbers not Growing.**—I do not think there is anything wrong in the management. We are all at times annoyed by matters turning out differently to what we expect; and often we experience the truth of the old adage, "The more haste the less speed." I always like to use new seeds for raising plants for early work; there is more vigour in them, and strength is everything in the short days. In the case under consideration I should expect to find either that old seeds had been used, or that the plants had received some check at some time or other, which has stunted them. A little thing does it early in the season—potting in cold soil, watering with cold water, or any little omission in some cultural detail—some oversight perhaps now forgotten.—H.

1774.—**Growing Herbs.**—For a good supply of fruit all the season plant a few roots in a warm, sunny place to come early, and a few roots in some cool position for use during hot weather. Mint is easily increased by separating the young shoots with a bit of root attached in spring, and planting in rows 6 in. or 8 in. apart. Thyme and Sage are best increased from cuttings in April, planted firmly with a dibble, to be watered and shaded for a time till they begin to grow. Make a new bed every year, as young plantations are the most reliable and stand the winter best. Sow Parsley now, and again in July; thin to 6 in. apart in August. Cut the largest leaves off a part of the crop to induce a new growth for winter. Plant a few roots in a warm spot for early use.—E. H.

1773.—**Plants for Screens.**—If a box or a border can be made outside the window—either to stand on the sill, if a box, or beneath, if a border—in either case creepers may be planted, trained up on each side of the window, and festooned across and allowed to hang down from the top. The Virginian Creeper, Clematis Jackmani, Canary Creeper, and Cobea scandens will make a good and cheap mixture. The two latter are summer creepers only. For winter, Ivies may be substituted. Another way, either in combination with a little light drapery outside or without, will be to have a few wire baskets made and filled with creeping or drooping plants, such as Campanulas, Sedums, Saxifrages, Tropæolums, Convolvuluses, Ivy-leaf Geraniums, &c.; the baskets to be hung from the top of the window, and the drooping growth to meet, or nearly so, the tops of the plants growing at the bottom of the window in pots or boxes in the usual way.—E.

1283.—**American Blackberries.**—I have seen no answer to the above, so I venture to offer my Canadian experience. I presume the querist means the Black Raspberry or Thimbleberry (Rubus occidentalis), as the American Blackberry (R. villosus) is almost identical with our own, and is not cultivated. The fruit of the Thimbleberry is abundant, and equal in flavour to the Red Raspberry; but it is much less juicy, the drooplets being so small. This might be corrected by cultivation; but I do not think it would answer in England, as the rampant growth would require a larger space than most gardens could afford; and I doubt whether the fruit would ripen well without the forcing heat of an American July.—Junia.

1747.—**Shrubs for Various Positions.**—I am afraid I scarcely understand the whole purport of "Wanderer's" question; but we will suppose he requires a few good shrubs for a shrubbery. The background.—There is plenty of choice among the smaller kinds of Coniferæ, the various forms of Cypress, Juniper, and Yew. If larger forms are admissible, the Deodar Cedar, Cryptomeria japonica, and Wellingtonia will suit. Among deciduous plants of rather large growth are Thorn, Laburnum, the Catalpa, Weeping Birch, Magnolias, and a host of others. Next may come Hollies—a host in themselves—Evergreen Oaks, Portugal Laurels, Boxes, a large family; and among flowering shrubs Lilacs, Guelder Rose, Syringas, and flowering Currants. Then, for the front, there are Rhododendrons, Berberries, Daphnes, Laurustinuses, Aucubas, Heaths, Azaleas, Pernet-

Cocos Weddelliana

tias, Spiræas, &c. I think "Wanderer's" difficulty would be met in most instances if he were to make a confidant of his nurseryman. We will say he requires a plant for a position that must, when fully grown, be no more than 10 ft. high. Any respectable man would, if on or near the spot, advise him what to plant, at the same time taking into consideration the climate and soil, as mistakes are often made in this respect. An interesting way of arranging shrubberies would be to group them according to families, not, as a botanist would do, but for effect, taking the best forms in each class only. Here we might say, for example, have a plantation of Hollies; elsewhere a bed of Berberries; then a mass of Spiræas, Magnolias, Thorns, and so on, giving each plant space to show its true character. Between those character groups might come in mixtures to heighten their effect. The Conifers, of course, would enter largely into any arrangement of the kind. Thus we might have groups of Cypress, Retinospora, &c.; only the dark, gloomy plants should, I think, be in contrast with the lighter and more cheerful colours of variegated Holly and deciduous plants.—E. H.

1715.—**How to Make a Garden Pay.**—Although the books mentioned in the question are doubtless unreliable, yet it should be understood that all books written specially to enforce garden facts are not to be read strictly in a literal sense, but rather as pointing out the direction in which learners and novices should go. Thus, statements as to prices of materials and payments for labour may be correct of one locality and wrong in another; but they must be read as indicative rather than as exact. Having an acre of ground, which it is desirable should be made to pay, considerations, such as the following enter: Is it proposed to market the produce, and if so, how convenient or otherwise is the market? Then, at what price can manure be purchased? as without a liberal supply of manure, the land being poor, the labour of cultivation would be largely in vain. Then, what is the local price of labour, and what is the rent and rate charges? All these things vary locally, and all must be understood and reckoned before the question of paying can be decided. The chief elements of success will be found in plenty of manure dressing, good and deep cultivation, and the growth of such crops as the soil may be specially adapted for. One man may cultivate an acre of ground into the highest possible condition, and profitably, if he grows some flower roots for sale, bush fruits, Strawberries, choice vegetables, early Potatoes, Marrows, Cucumbers in frames, and similar things, that cannot be produced except where there is considerable outlay of labour and incessant attention. All such things will command double the price paid for products grown under ordinary market garden culture. Capital and energy well directed may make a success out of only an acre of ground.—A. D.

1736.—**Potatoes for Exhibition.**—Good cultivation has usually more to do with the production of handsome samples of Potatoes than mixtures; but those who have stiff, close soils are at a disadvantage when in competition with those who have a nice light friable soil of good quality. To bring stiff soils into suitable condition for Potato cultivation, it is well to throw up into sharp ridges early in the winter, not less than 3 ft. in width. Early in the spring lay into the furrows a moderate dressing of fresh stable manure and fork in deeply. About the end of March add, if to be had, a dressing of wood-ashes, or pounded charcoal, or soot, and with it some good artificial manure, all of which fork in again very lightly; and, drawing a shallow drill with a hoe, plant the sets, earthing over by covering with a fork sufficiently to bury the sets about 4 in., and fork down the intervening spaces when convenient, so as to have the soil as fine as possible for earthing. There are also in the growth of Potatoes for exhibition such important features as the selection of sorts, preparation of sets, best times for planting and lifting, selection of show samples, care of them after lifting, and many other points that growers should have at their fingers' ends. It may be of interest to say that having during the past winter had a large piece of exhausted Strawberry plants growing on very stiff soil trenched in, we are now preparing to plant by having shallow furrows thrown out, and in these shall place the sets, and employ as dressing, as an important trial, malt-dust, Amies' manure, Clay's fertiliser, and two kinds of Hill's manure for Potatoes; and we look for some very interesting results.—A. D.

1789.—**Blue Flower for North Aspect.**—We know of nothing better than Blue Lobelia. The seed, must, however, be sown under glass. In a window would do, covering the pot with a pane of glass, and shading until the plants are above ground. For another season we would, however, recommend the varieties of Viola cornuta, the seed of which may be sown in August, planting out the following March. This is a hardy perennial of dwarf habit, flowering continually throughout the summer, and would probably succeed better than most summer-flowering plants in such a sun secluded situation.—B.

1727.—**Cats in Gardens.**—You must catch them, and drown them as fast as you catch them. Have a large trap made with a falling door at each end, and bait it with valerian. You will catch one every night.—MAJOR.

1771.—**Lawn Tennis Court.**—Take up the turf, level the ground (or at least reduce the incline as much as possible), make it firm by ramming or otherwise; spread over the firm surface 1 in. or so of sifted coal-ashes, and on this lay the turf. The coal-ashes will keep out worms, and tend to make the turf finer and thicker. It should be 100 ft. long, and 80 ft. wide.—E. H.

1772.—**Uses of Sulphate of Ammonia.**—Sulphate of ammonia is a white crystallized substance, and may be used in a liquid form—about 1 oz. to 4 gals. of water—and given to growing crops; or it may be sprinkled over the beds at the rate of 2 lb. to the square rod or perch in spring.—E. H.

1778.—**A Good Winter Vegetable.**—To obtain large white Leeks, treat them as Celery plants are treated; that is, sow a few seeds in a gentle hotbed at once; prick off as soon as large enough, and plant out finally in trenches when the plants are strong. The plants may be 1 ft. apart in the trenches; earth up to blanch as required. For ordinary use very good results are obtained by sowing this month in the open air, and transplanting into the trenches when the plants are large enough.—E. H.

1790.—**Budding Plum Stocks.**—Graft the Plum stocks where they now are, and move them in the autumn. Apples will not come to perfection grafted on Plum suckers.—E. H.

1742.—**Fern Cases.**—Isolepis gracilis or any of the free-growing Selaginellas, such as Martensi, serpens, or the true denticulata, would produce an excellent effect in a basket. Selaginella cæsia arborea is a beautiful climbing mass; and Lygodium scandens is a pretty Fern of climbing habit.—C.

1716.—**Packing Trees for a Voyage.**—The best time for packing the trees would be in the autumn, when the leaves are fallen. We would, however, advise you to get them packed by a nursery firm accustomed to that kind of work.—J. C.

1740.—**Treatment of Dracænas.**—When a foliage plant has gone bad it is difficult to reinstate it in health. All that can be done is—sponge the leaves frequently, water carefully (that is, allowing the soil to dry out, and then giving enough water to thoroughly moisten it), and admit air on favourable occasions.—J. C.

1741.—**Last Year's Seeds.**—If the seeds in question have been kept in a dry, cool place they will germinate very well, perhaps better even than those saved during the past summer, which was generally so unfavourable to the production of well-matured seeds.—J. C.

1730.—**Pruning Roses.**—In order to induce the trees to flower freely at the close of the summer, they should be liberally treated during the summer months. By frequently and copiously watering in hot weather with liquid manure, a succession of good blooms will be maintained. The foliage should also be freely syringed after hot days. Pruning, if not completed, should be done at once.—J. C.

1719.—**New Zealand Flax** (Phormium tenax).—Sow now in well-drained pans of sandy loam and leaf-mould. Cover the pan with a pane of glass, place in a warm house, and shade from the hot sun. Or the seed may be sown in May in a cold frame.—C.

1718.—**Nitrate for Plants.**—The proper way to use this is as a top-dressing, sprinkling a little on the surface soil around the plants, choosing a rainy period for the operation.—C. B.

1752.—**Clematises for Bedding.**—Clematises may be safely planted during the next three weeks. The soil should be deeply dug and well manured. Begin in the centre with a single plant, around which the remaining plants may be set in circles 18 in. apart, and the same distance from plant to plant, placing them alternately. Water freely in dry weather. Lanuginosa candida and L. nivea (white); Jackmani and rubro-violacea (purple); Lady Bovill (blue); and viticella rubra grandiflora (claret-red).—C.

1738.—**Climbers for Walls.**—Your Magnolia was probably the shy-flowering variety. We would procure a plant of the Exmouth variety, which flowers in a young state. There is also Ampelopsis Veitchi (so beautiful in the autumn), Clematises, and Cotoneaster microphylla.—J. C. B.

1567.—**Worms in Gardens.**—Take 1 quart of fresh slaked lime, and put it into 6 gallons of water; stir it well; then let it stand till quite clear. Roll the lawn or walk, or beat the ground gently with the spade; this should be done in the morning. Then leave it till the next morning; this will give the worms time to come and clear the mouths of their hole. They being then near the surface, take a watering-can with a rose on, and draw off the lime-water quite clear, and water the ground; the worms will all come out on the surface directly; then sweep them up, and do what you like with them.—J. SEAGRAVE.

1414.—**Best Sorts of Willows.**—Some of the best kinds of Willow are—Salex viminalis, rods 9 ft. to 12 ft. long; Salex vitellina, yellowish bark, rods 3 ft. to 6 ft. long (this is the best kind for garden work); Salex rubra, reddish colour, rods 4 ft. to 6 ft. long. Make cuttings in spring; the wood may be either one or two years old the cuttings to be about the thickness of a man's finger and 1 ft. long. Plant in rows 12 in. to 16 in. apart, and 8 in. to 12 in. between the cuttings. Drive the cuttings deeply into the ground, leaving not more than 1 in. of the cutting above the surface; the plants in one row to be opposite the spaces in the rows on either side of it.—OMBRI.

1717.—**Rhododendron Leaves Going Brown.** Transplanted Rhododendrons have in many instances suffered this winter. The plants in question will probably make healthy growth this season, if attended to in the way of watering. We would not prune them.—C.

1862.—**Coronilla glauca.**—*Bot.*—You probably mean this plant. You can make the plants more bushy by placing a stake in the centre of each, and tying the shoots in to it. In May the plants may be planted out in a sunny border in a rich soil; and if lifted autumn will make fine plants for winter blooming.

1863.—**Propagating Yuccas.**—I have Yucca, from the root of which two small ones have sprung up. What should I do with these?—F. A. [Let them grow for another month or so, then partly sever them from the parent plant, and earth fine soil round the root. Keep this soil moist, and they may root into it. At August completely sever them from the parent plant, and in a week or two after pot them and place them in a shady place till established.]

1864.—**Propagating Frame.**—I have propagating frame heated by pipes passing through cemented cistern filled with water; the cistern is covered with slates. I have put 6 in. of cocoa-nut-fibre part of the slates, and on the other part 1 in. of sand. The water in the cistern can be raised to a temperature 120°; the slates also attain nearly the same, but the heat will neither rise through the cocoa-nut fibre nor sand; consequently the temperature in upper part of frame is never above 60°. Both cuttings and seeds are doing badly. Please tell me the cause and remedy, as, when I put up the place, I thought anything would strike with the greatest facility.—K. [One of the pipes would pass round or along the front of the frame to apply top-heat.]

1865.—**Crops Under Orchard Trees.**—What is the best crop to grow under standard Apples, which are 16 ft. apart? Will Currants, Gooseberries, dwarf Plums or Cherries, or vegetables answer?—J. [If the trees are not too large, Gooseberries and Cats will do well; so will Rhubarb, Brussels Sprouts, Kales, &c. Morello Cherries would also do, and apples dwarf Plums; also Nuts.]

1866.—**Pelargoniums and Cacti.**—What kind of soil would be the best for Pelargoniums Cacti, and what is the best aspect for them?—HENRY. [Sandy loam and decayed cow manure for Pelaums; and sandy loam and old mortar-rubbish for C Pelargoniums want a light, sunny, and airy posit Cacti will do nearly anywhere.]

1867.—**Bulbs after Flowering.**—Will be better to leave Tulips, Snowdrops, Crocuses, Hyahs, &c., in the ground, or take them up and plare them in the autumn?—ANN. [Leave them in the gro]

1868.—**Tuberoses Out-of-doors.**—Will Tuberoses grow without heat?—W. A. R. [Yes, in a frame or greenhouse. Out-of-doors they will grow the flowers will not be open before cold weather set

1869.—**Pruning Eschallonias.**—Is a fine Eschallonia rubra, which flowered incely all last summer; it is much cut up by frost, is shooting again from the larger branches. Shoube cut back? how much? and when?—JUNIA. [Aflowering you might prune it so as to make the bushy and shapely.]

1870.—**Celery for Seed.**—I have two roots of Celery for seed; how must I treat th—A NOVICE. [Plant them in good soil, and keep thell watered. Do not earth them up.]

1871.—**Gooseberries Throwing Suckers.**—My Gooseberry trees send up a numbshoots from the roots, spoiling the appearance of thes. What is the cause and what the remedy?—A RY VICAR. [The cause is difficult to ascertain. Fo among the trees will sometimes cause it. The remeo cut them out.]

1872.—**Permanent Bulbs.**—I havting now in my garden Lilies of various sorts—Nus, Crown Imperials, Tulips, Hyacinths, Crocus, s, English and Spanish Irises. I wish to have as is possible permanently in the ground, to save trou which is it absolutely necessary to take up after flg?—BULBOUS. [None of the bulbs named ought taken up. Give them a mulching of rotten manure imer and a coat of ashes in winter, and all will be w

Soot and Lime for Onions.—*J.*—These help to kill grubs in Onion beds. If put efore the Onions are sown, all the better; but a litt may be applied after the Onions are even above d. Lime is not so good as a little salt.

C. Andrews.—You may pluck the bud fr aréchal Niel Rose without in any way injuring th. Send your volume of GARDENING to our office nding—price 3s.

Bedding Plants in Pots.—*J. M. A* aniums always flower better when planted in the n pots than when turned out. The size of the is immaterial.

Perennial Phloxes.—*C. M. H.*—See NING, March 6th, 1880.

W. S., Belvedere.—Send us a bit of the pl

QUERIES.

1873.—**Lilies in Windows.**—Having received some bulbs of the hardy Japanese Lily, and not knowing the best way to manage them, I should be obliged by a few hints on the subject. Also whether they are fit for pot culture in a room facing east, and the best means of propagating them.—PHŒBUS.

1874.—**Cesspools in Gardens.**—In my garden are two cesspools—one for the house drains and one for the water from the baths, pantry, and scullery. I shall be obliged if some one will tell me how I may best utilise the contents of these in the garden. I must keep them emptied somehow, as the subsoil is clay, and nothing will soak away. I have no stable, and manure is expensive, so I shall be glad, if possible, to use the contents instead. I should like also to know the best plan of disposing of the cut Grass, &c., during the summer, so as to make it useful, and yet not to have an untidy rubbish heap. The soil of the garden is a good loam.—COUNTRY VICAR.

1875.—**Keeping a Window Gay.**—I have a sunny bay-window not far from London, which I wish to keep as gay as possible throughout the year. I have an unheated frame, but it gets very little sun. Will any one tell me what plants to grow?—W.

1876.—**Plants for Small Greenhouse.**—Will some one give me a short list of the most suitable hard-wooded and soft-wooded plants for a small house 15 ft. long, to be heated in winter by one of Gillingham's generators? Also, if not too much trouble, the names and number of greenhouse climbers suitable for the above?—G. P.

1877.—**Gardenias.**—What treatment do these require to grow them well?—AMATEUR.

1878.—**How to Grow Aconites.**—Can any one tell me how to grow Aconites?—MONTE CHRISTO.

1879.—**Propagating Aralia Sieboldi.**—How can I propagate this plant?—BOT.

1880.—**Camellias from Seed.**—I have upon two occasions sown Camellia seeds, but none ever came up. I am about to repeat the experiment this year; will some one inform me what should be done to ensure success?—O. G. K. Y.

1881.—**Plants for Baskets.**—I have nine hanging wire baskets. Will some one inform me what seeds I had better obtain, so that I can have a good display in them this summer; they will be hung in a glass passage.—NELSON.

1882.—**Unheated Greenhouses.**—Under this head a very useful article appeared in No. 51 of GARDENING. Will Mr. Grieve, the writer of it, kindly inform us if his pipes, placed quite flat, as he says, for the whole length of 18 ft., will not be a failure as regards the smoke passing freely up them? or, more strictly speaking, will not the draught be very imperfect? I am about trying it.—A. W. G.

1883.—**Rose Leaves Spotted.**—Can anyone tell me the reason why the leaves of my Maréchal Niel Rose in the greenhouse have become suddenly covered with large brown spots?—PINK MAY.

1884.—**Propagating Bouvardias.**—How can I propagate scarlet and white Bouvardias; and what treatment should they have now they have done flowering.—PINK MAY.

1885.—**The May-flower** (Epigæa repens).—The late Mr. Masters, of Canterbury, told me he had once had the May-flower, but had lost it, and that it was very difficult, almost impossible, to grow it in England. I was not, however, discouraged, but have beeen unable to procure it anywhere, and should be glad if any of your correspondents could tell me where it is to be had.—JUNIA.

1886.—**Hardy Annuals, &c.**—I want to know the name of about a dozen hardy annuals that I can sow now in pots and outdoor in a very small back garden (in a town), having only three to four hours' sun, from 9 a.m. to 1 p.m., that will flower the best, the most, and the longest during the year, and that I can cut bunches of flowers from in the summer and autumn. Of course, the pots can have the sun in the window for five or six hours from mid-day.—P. M. C.

1887.—**Water in Aquaria Turning Green.**—I have three small plants of the Cape Pond weed and a small Arum Lily growing in an inverted bell-glass for some time. The water has been changed occasionally, and the plants have grown well. About a fortnight since a slimy greenish substance appeared on the water and on the stems. How can this be obviated?—T. B. M.

1888.—**Blooms Falling off Roses.**—I have a Maréchal Niel Rose tree in a 12-in. pot in a greenhouse trained to the wall. There has been a many buds on which have partly opened, then dropped and died off: the tree itself appears healthy enough, and has made a deal of new wood. Can any reader tell me the cause of this?—S. E.

1889.—**Cones on the Deodar.**—Have any of your readers noticed cones on the Deodar this year? Ours has had several, which we believe to be an unusual circumstance.—M. W.

1890.—**Clematis from Seed.**—Can any reader give me any hints on growing Clematis from seed?—A. B.

1891.—**Cobea scandens from Seed.**—I grow this from seed and get nice plants, but they never flower, and they die in the winter. I grow them in a greenhouse heated by a flue. How can I make them bloom?—A. B.

1892.—**A Trap for Birds.**—Could any one suggest a way of making an inexpensive bird-trap, by which I may preserve the birds for stuffing? I do not like gins.—LOCO.

1893.—**Management of Fern Case.**—I have a large earthenware Fern stand or case covered with a glass that fits it very tightly. I have had it filled at a nursery with choice Ferns, and would be glad to know the proper management of Ferns in such cases.—J.

1894.—**Cyclamens and Cacti Blooming.**—What should be done with these when they have done blooming?—G. B.

1895.—**Green Flower Pots.**—Is there any way of restoring the colour of and removing the stains from garden-pots? I have not found scrubbing of any use.—G. B.

1896.—**Narcissi Failing.**—I potted some bulbs of Polyanthus Narcissus in the autumn, at the same time and in the same manner as some Hyacinths. The latter all came up and are blooming beautifully, but all of the Narcissi except one have failed. They have made no roots, and have decayed in the pots. They were all plunged in ashes until the spikes came up, and were treated, as directed, exactly like Hyacinths. What is the cause of their failure? They had begun to grow out rather before they were potted.—A HARMLESS BULLFINCH.

1897.—**Cucumbers on a Landing.**—I have a recess from the half-landing of my house facing the sun. It has a glass roof, glass front, and one side glass and one brick; it is open to the house; the dimensions are as follows—height 8 ft., width 7 ft., and 3 ft. 6in. deep. Would any one inform me if I can grow Cucumbers in such a place, and what size pot I should require; also the sort that would do best? I presume the shoots would have to be trained on wires up and across. Also the time for planting, and soil, &c.—A. J.

1898.—**Camellia in Open Air.**—I have a Camellia in my garden which has stood the winter without any protection. It looks in a very forlorn condition, but it is not dead. Can I do anything to save its life?—LEICESTERSHIRE.

1899.—**Plants for Lancashire.**—Will any reader inform me what plant or seeds will suit and live in Lancashire, about half a mile from large blast furnaces, from which the wind brings gas and sulphur, which is poisonous? I have had Rhodendron and ordinary white Rose trees, but they are dying gradually. Also, what seeds are the most hardy ones, for flowering in the open garden this year? When am I to sow the seeds; or will plants do best? What kind of shrubs are likely to stand this climate and gas?—H. A.

1900.—**Cats in Gardens.**—My small garden is damaged by the visits of cats. I have heard that essence of Valerian is very attractive to them. As I have a number of plants of this growing here, would this be one of the reasons for there fondness for scampering over my beds? Would any one say if they know of any plant to which they take special objection?—H. P. S.

BEES.

Starting Beekeeping.—If you are going to have a swarm it would be advisable to have it as soon as hived, which would probably be about the end of May or early in June. You would get the most honey by slinging. There is a great variety of hives; I should advise a bar frame. The bees would require feeding on their arrival, and afterwards if the weather was bad. Nearly any situation would suit them excepting being shaded entirely from the sun, as they would be under a wall facing the north. They should be packed in a box with lid of perforated zinc. An average stock would produce 30 lbs. of honey at least in a good year and good district.—E. W.

—— It is usually considered the best plan to get in stocks of bees in the late autumn in preference to the spring, as the bees get more accustomed to the new locality ere the active spring season comes; but if not so obtained, then the sooner now the better. Whatever kind of hive the bees may be in when sent on a journey there should be a piece of perforated zinc fixed securely over the entrance hole, and then the hive with its floor-board may be packed into a case, not too close fitting, but secure; or some strips may be fixed with screws to the floor-board, and from these others carried crosswise over the top of the hive, all firmly screwed; and this will enable the hive to be carried any distance in perfect safety. The simplest hives are the straw skeps so commonly used, and these are most suitable for novices. It is only practised hands who can safely employ the bar-frame and other patent hives. The floor-board should be of Elm, and instead of cutting the straw of the hive a groove about ⅛ in. deep and 1½ in. in width should be cut in the board, gradually deepening outwards. This throws off all rain or other moisture. In the top of the hive should be a hole 2 in. across, over which should be placed the straw super which is usually put on after the first swarm has come out. Into this super the bees convey their honey, and when that is removed in the autumn it is well to let the insects have what honey is left in the hive for their winter's sustenance; but if there is not enough, then feeding with properly-made syrup from a bottle inverted over the hole at the top must take place. It may be cheaper to take the honey and feed up again, but it is not quite the proper thing to do, and the gain is doubtful. As to produce, a strong stock in a good season may give from 15 lbs. to 20 lbs. of honey, but all this depends upon so many local conditions that it is impossible to give an exact estimate.—A. D.

AQUARIA.

HOW TO MAKE AND STOCK AN AQUARIUM.

AFTER I got my aquarium from the tinsmith (for it is made of tin, for lightness), I gave it two coats of white paint inside and out. When it was dry, I got my glass cut to the size required, which is 22½ in. long, 14½ in. high, and 14 in. broad, without the stand (which is made of wood). The glass I bought was 21 oz. to the foot; 32 oz. might be used. I then thought that white lead made into a soft putty must be better than red lead and other materials commonly used, and have found it better for the purpose. In bedding the glass into the frame, I put it as close up to the frame as possible; to do so, the glass should be quite flat, and cut to meet at the edges and no more. After this I let it stand to dry for two or three weeks. I then cleaned the glass, and painted the tin and wood outside with two more coats of white paint, and then finished with two coats of enamel white varnish, and after gilding the four top corners it was ready for use.

To keep the dust out I got an ordinary stretching frame made to rest on the top of corners, and covered it with very open muslin, with edging round like an awning; and the aquarium, now standing on a level with the eye when sitting, looks very well indeed. I then made my rockery of petrified Moss—a very light rock found round all ponds in the country (as light as pumice stone), in pieces as big as my hand; which I fastened together with Portland cement round a piece of wire, and bent to the size of the rock I required, making a passage through the rock both ways. With a little patience and taste you can make a very pretty rockery with the above (but virgin cork I think, would never do). I built my rockery on a roofing slate to make it stand firm. I then got some very small gravel, washed it and boiled it, and washed it after it was boiled to purify it, and put it round the rock all over the bottom 2 in. deep to set the plants in. As to a fountain, if you wish to keep your fish alive, you must not have one at all, as the plants and snails keep the water clean, while fresh water kills the fish.

As to stocking an aquarium, I think the best plants are Vallisneria spiralis and the Anacharis; but the first mentioned look the best, and grows the fastest, and accordingly gives the most vegetable matter and oxygen to the water. I would have, for an aquarium 36 in. by 12 in. by 14 in., three dozen trumpet snails and one dozen pladden snails, for they are the scavengers, and keep the plants clean. Then as to fish, for such an aquarium as "Mellgate" intends to have, I would put in thirty gold-fish and ten minnows, and no others. For the quantity of plants I would recommend four dozen plants of Vallisnera set in rows of four together. The above is about what I have in mine and it looks very well. It must be shaded when the sun shines on it.

H. G. SUNDERLAND.

POULTRY.

Serious Loss of Fowls.—I have lost seventeen fancy fowls, and no one can tell me the cause. Six died one day and eleven the next. Some moped for a few hours before their death, and others were ill only half-an-hour before they died. In each case their intestines and egg organs came out and occasioned much suffering, and ultimately the death of the bird. I have had them analysed for poison by Dr. Lapper, analyst, but none has been found. Their food was pollard, oats, bran, potatoes, and Indian meal, besides greens and household scraps. There was lime for building in the yard where they were kept, but I should not think eating it caused death, as these were healthy fowls where they were bought.—N. S. DURRANT.

Weight of Eggs.—Poultry-keepers are fond of telling the number of eggs laid to them by their fowls during the year, and taking credit for so much profit resulting from them. As I have always kept my fowls for pleasure and the particular gratification of having bonâ fide new-laid eggs for my own table, or a nice chicken when wanted that could be guaranteed tender, I have never entered into any pecuniary estimate of profit and loss. But it is evident there are eggs, and eggs. I have just weighed several

from my own fowls, mostly half-bred Dorkings, and find they vary in weight from 2½, 2¼, 2 and 1¾ oz., there thus being a difference of just ¾ oz. between the smallest and the largest. Perhaps the fairest estimate of egg produce per annum would be found in the weight of the total, and not in the number, as the hens that lay the most eggs may also lay the smallest ones.—H. D.

Houdan Fowls.—I can bear testimony to the excellence of these fowls, both as layers and for the table. I have kept many sorts, and made as much as £65 in one year; but I certainly prefer Houdans. They are essentially non-sitters. Ours laid last year from early in February until the last week in August, the eggs being very fine and of an excellent flavour; while for table I consider the chickens equal to Dorking.—E. W.

Fowls Paralysed.—My fowls get partly paralysed in their legs. Can any one tell me the reason and remedy for it.—BELMONT.

Eggs for Hatching.—I have two black Spanish fowls—a cock and a hen, about ten months old. Will the eggs from the hen be fit for hatching, or are the birds too young?—E. S. W.

Fowls' Claw-nails Coming off.—I have a young black Spanish cock, about six months old, whose claw nails all went black, and subsequently rotted off. Will the nails grow again?—J. SICE.

Leghorn Fowls.—I should be glad if anyone could give me a little information about Leghorn fowls, as I thought of getting a few. Will they stand confinement well? Are they hardy, good layers, and non-sitters, and are the white or brown ones best?—NEW-LAID.

Pale-yolked Eggs.—I keep about twenty fowls; half of them are Black Hamburgh, and the others cross-bred. They seem in good health, and lay fairly well, but the yolks of the eggs are very pale. Will any one kindly tell me the cause and remedy?—B. H.

Fowls Plucking Each Other.—Can any reader tell me how to prevent fowls from pecking the feathers off each other and swallowing them? They commenced doing so about a month ago, and now they have but very few feathers left on their bodies and necks. Since they have been in that state they have laid but few eggs.—H. J. W.

HOTBED FOR RAISING SEEDS.

THE annexed illustration represents a hotbed or heated frame which I have in my greenhouse, and which I found very useful for raising seeds and cuttings.

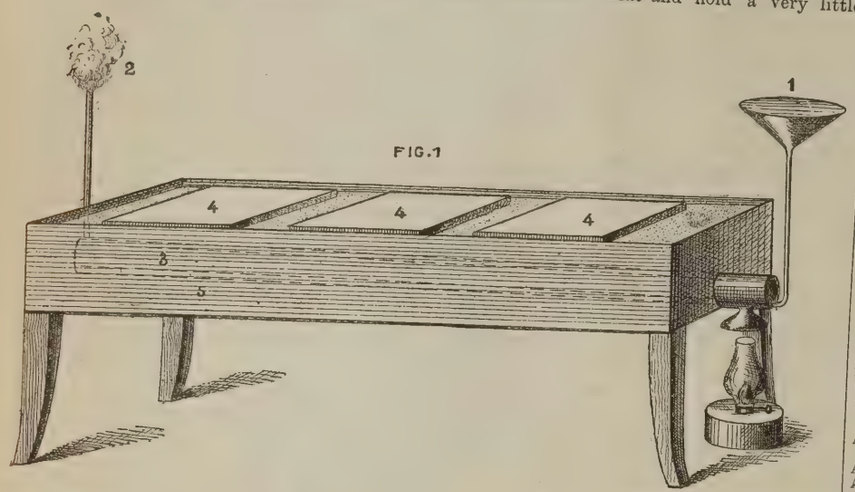

FIG. 1

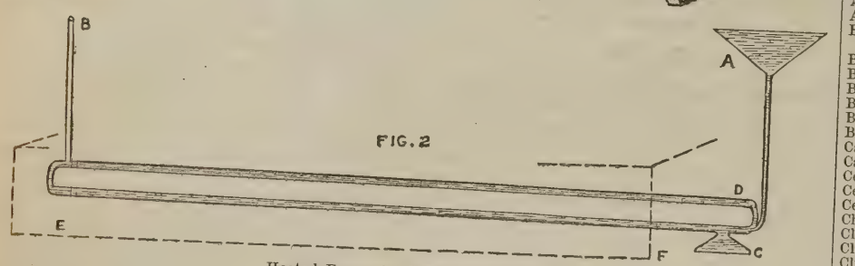

FIG. 2

Heated Frame for Seeds and Cuttings.

Length of Pipe D, made of zinc, 48 in.; diameter of pipe (outer one) 4½ in.; diameter of pipe, (inner one) 3¾ in. Cistern (A) to hold about one gill or so, and to be about the height of the top of the box; or it need only be a few inches above the pipe D. Air-pipe (B) must be about 2 in. higher than cistern (A).; the little boiler (C) about the size of an inverted tea-saucer.; length of box 44 in., depth 10 in., width 10 in. The lamp should have a glass or tin chimney, and the wick, if 1¼ in. or 1½ in. wide, will make the water very hot. The pipe D should be 1 in. higher at E than F, as the hot water will rise to the highest point. Put Cocoa-nut fibre in the box to cover the pipe about 1 in. or so, and keep moist; also cover the box with glass to keep in the moisture. The dimensions need not be exactly as I have given them, but could be made suitable to the space where it is to be fixed. The idea of the inner pipe is so that the outer one will have a good surface of heat and hold a very little water; and when the water is once hot it will require but a small flame to keep it so.

A Cheap Hotbed for Raising Cucumbers.—I procured an ordinary bloater box, filled it with Cocoa-nut fibre, into which I plunged my pots with one seed in each. I covered the box with a sheet of glass, and placed it on a sheet of tin on the stage of my greenhouse, the stage being composed of pantile laths 2 in. apart. I have a stove with 1½-in. burner, which I place underneath the box; the lid of the stove removed gives sufficient heat to raise the young plants in four days and nights. An ordinary 1s. lamp would answer the same purpose, but requires filling oftener.—BROCKLESBY.

Law respecting Greenhouses.—I regret to have to inform you and your readers that in a case tried to-day (March 23) in the Worship Street Police Court the sitting magistrate decided diametrically opposite to the decision in the Clerkenwell Court quoted in your issue of December 20, 1879. I was summoned for "constructing the enclosing walls below the sashes of less thickness than required by the 1st schedule, and without the damp course required by By-law No. 2." I took my stand on cap. vi., part i., par. 14: "All party fence walls are exempt." The magistrate referred to interpretation of terms for "party fence walls," and finding no definition of same, held that "party fence walls" only meant walls separating one ownership from another. I maintained that "party fence walls" mean any fence or wall intended to include, exclude, or part off anything, and not to act as a support. My greenhouse, 12 ft. by 10 ft., being constructed of a self-supporting frame, consisting of doors, windows, and sashes, I therefore contended that the filling up with bricks and cement did not constitute a wall within the meaning of the act, or that, at any rate, if a wall at all, it was simply a party fence wall, and as such exempt. The case has been adjourned for three weeks; and having, in the interests of the gardening world, asked the magistrate to grant me a case, I would suggest that joint action should be taken, and shall be glad to hear from any of your readers who may feel disposed to assist me in trying the question in a superior court.—UPFIELD GREEN.

Garden Labels.—At this season of the year, when a great number of labels are required for seed-pans, boxes, cuttings, &c., amateurs who do not wish to buy can most easily make them out of the top and bottom sides of an old band-box; fifty to one hundred, according to size, can be cut, with a strong pair of scissors, out of one top and bottom. The paper can easily be removed by soaking in water, and if a little white paint be rubbed on them the names may be written with a carbon or "solid ink" pencil. —THRIFT.

Solanums and Mice.—Mice have a particular fondness for the berries of the Solanum, but as soon as their depredations are discovered I have checked them in the case of standard plants by putting a collar made of cardboard half-way up the stem, beyond which they could not pass. In the case of bush plants the simple expedient of placing them upon inverted pots, so as to elevate them several inches above the pots of the surrounding plants, proved to be an effectual bar to their incursions. Of course traps were not neglected. The old figure 4 trap is one of the best in my experience, and it can be made in five minutes or so.—A.

We shall be greatly obliged to any readers who call the attention of cottagers and working men to the aid which all who cultivate their own gardens may derive from the numerous articles, notes, and answers, in this journal. No periodical ever published contains so much purely practical and trustworthy information on the art of gardening.

FINE-LEAVED HOTHOUSE PLANTS.

AMONG plants grown for the beauty of their foliage alone, there are few that better repay good culture than the Alocasias They are rapid-growing plants, and may therefore soon be grown into large specimens for exhibition, or for occupying prominent positions in the hothouse. Alocasias delight in shade and plenty of atmospheric moisture, which can be secured by placing them on inverted pots over tanks, that the bottoms of those in which they are growing may stand an inch or two clear of the water. In such positions they are very easy to cultivate, and rarely show any disfigurement round the edges of the leaves, as they sometimes do when there are sudden fluctuations in the amount of humidity immediately surrounding them. Young plants of Alocasias must be kept well above the rim of the pot when shifting them into others of larger size. Well drain by the use of plenty of crocks, and put in a mixture of rough fibry peat and Sphagnum, packing it closely and securely round the collars of the plants, taking care not to injure the points of the large fleshy roots protruding through the old ball. When packing the fresh material about them, shake in a little silver sand, and place a few pieces of charcoal amongst the peat and Sphagnum to ensure its porosity; after which water freely during the remainder of the growing season. A. macrorhiza variegata requires different treatment as to soil and the way it is potted, for which purpose good fibry loam and peat, used in a rough state, is the most suitable. This, like the others, requires plenty of water while growing, and must therefore be well drained. The same conditions as to atmospheric moisture and shade necessary for the others will suit this perfectly. This variety has, unfortunately, a tendency to revert to the green form and lose its variegation; therefore, in making the requisite divisions for potting, only those showing the best marked leaves should be retained for growing on. Alocasia intermedia, which we now figure, is one of the most handsome kinds. When well grown it is a noble fine-foliaged plant, suitable alike for the decoration of the plant stove or for purposes of exhibition. In habit it somewhat resembles A. Lowi, but it is even more stately than that species, while its leaf-stalks are conspicuously mottled or barred in a very beautiful manner. This plant is propagated by dividing its fleshy rhizomes; and, being of vigorous habit, it soon makes a good specimen if potted carefully in a fresh open compost, consisting of fibrous peat, turfy loam, and leaf-mould, with sufficient coarse sandstone grit to keep the whole open and porous; and if a covering of fresh living Sphagnum be placed over the tops of the pots, near the root-stocks, fresh roots soon make their appearance there, a circumstance which adds considerably to the health of the plants. Alocasia metallica is one of the oldest and most distinct and beautiful of fine-foliaged stove plants, striking in the form of a large specimen, and also serviceable and effective as a small vase or table plant, the young foliage being especially lustrous and handsome. For very large specimens select five or six of the strongest crowns or root-stocks, and taking some 15-in. pots, fill them one-third full of crocks, over which is placed a good layer of fresh Sphagnum Moss, to keep the soil from being washed down and blocking up the drainage, as during the growing season abundance of water, both at the roots and overhead, is required. The compost which

A FINE LEAVED STOVE PLANT (ALOCASIA INTERMEDIA).

we use consists of fibry turf, peat, charcoal, broken potsherds, and chopped Sphagnum Moss. The crowns or root-stocks, which are long in shape, are raised well up in the centre, packing the soil amongst them, so as to form a cone. If potted in February, they will throw up a quantity of flower-spathes before the foliage, but these should be broken off as soon as they appear, in order to direct the whole energy of the plants to the formation of fine foliage. Smaller crowns, placed three in a 6-in. pot, make fine vase plants in autumn and winter; and single crowns in 3-in. pots are also highly effective in table and plant stands, their polished shield-like leaves contrasting well with whatever they may be associated. They are not liable to attacks from insects, but a sponging occasionally ensures cleanliness, and greatly enhances the beauty of their leaves. The following is a list of the best kinds of Alocasias in cultivation in the best nurseries about London, viz.—gigantea, hybrida, intermedia, Jenningsi, Lowi, macrorrhiza variegata, Marshalli, metallica, Sedeni, Veitchi, and zebrina.

Caladium esculentum is a noble-leaved plant when well grown; and for adding a semi-tropical character to the flower garden through the summer and early autumn months, few plants are better adapted than this Caladium. In warm, sheltered localities it makes a free and rapid growth, especially when planted in prepared soil of a light and sandy character, well enriched with rotten manure. For large clumps or masses it is well adapted, as a strong tuber planted in a warm nook soon establishes itself, and forms a good specimen. This species is no more difficult to manage than a common Canna, while its bold foliage is unique and strikingly effective, especially in the vicinity of water. It is extremely easy to propagate by dividing large tubers, and it may be kept through the winter in any shed or cellar where frost is not admitted. Being a gross feeder and of rapid growth, it follows that an abundant supply of water at the root must be given when growing, while when the roots are removed indoors in autumn they may be preserved through the winter in moist sand or earth. When grown under glass in a warm, moist atmosphere, its leaves attain an immense size, and it also makes an excellent conservatory or window plant when grown in small pots. When growing, liberal supplies of manure-water will greatly improve its growth.

Indian Kale (Caladium esculentum).

Monstera deliciosa is another fine-leaved plant which under good culture may be induced to bear large edible fruits. The elements of success in the culture of this tropical fruit are heat, light, and moisture, and, provided these necessary conditions be one and all supplied, success will be ensured. Any form of training may be adopted which will bring the plant well up towards the glass. It may be made to cover a portion or the whole of the back wall trellis, or, what is preferable, it may be trained round forked tree stumps, a system which suits it admirably. It may be grown in a tub, but it is best planted out in a good body of fibrous peat and loam in equal proportions, which should rest upon a good drainage of brick rubble. Thus placed, unlimited supplies of water may be given in hot weather, and the fruit will be fine in quality and abundant. Although the Monstera will thrive in a low temperature, it will not develop its true character as a fruit-bearing plant unless a brisk growing heat be maintained during the spring and early summer months. In a conservatory or greenhouse it is, however, well worth growing for its foliage alone, and it is often used in the sub-tropical garden during the summer months.

Sanchezia nobilis is an excellent fine-leaved plant for conservatory decoration during the summer months. It is alike remarkable for the size of its leaves and the rich yellow bands of colour traversing each side of the principal veins. From the great substance of the foliage, and the comparatively hardy nature of the plant over most other stove subjects, it stands well in the cool, dry air of a conservatory and in positions where it would be quite unsafe to place Crotons, with many of which in point of leaf-markings the Sanchezia will compare most favourably. Cuttings put in now under hand-lights in any shady part of the stove will soon root; and, if grown freely on during the summer, make fine useful plants for next season. To get the leaves of large size, they must be potted in good fibry loam and leaf-soil, with sufficient sand to keep the whole porous and open, that water, of which they take liberal supplies when growing, may pass freely through. Any about to be removed for decorative purposes should first be placed in a cooler and more airy house than that in which they have been grown, so as to harden them gradually and prepare them for the change. In order to have their leaves in the best possible condition, they should be frequently sponged, to remove dust or other deposit that may have gathered on them from the impurity of water used in syringing.

Propagation of Fine-leaved Plants.—Cuttings of Cyanophyllums, Aralias, Crotons, Dracænas, Ficuses, &c., should be taken off as soon as they are large enough for the purpose. In the case of most of them the young shoots that are formed after heading back root much more readily than the points of the strong branches, especially when obtained with a heel, as they can be got at this stage of their growth. All the larger-leaved plants of this description require sufficient room in the cutting-pots, or they are liable to damp off; and every effort should be made to retain in perfect condition the whole of the leaves which they possess, as upon being clothed with perfect foliage down to the base depends their appearance afterwards. Plants that require to be increased by division of the crowns are easiest managed about the time when they commence growth. Some of the species of Pandanus, Musas, Hedychiums, Cyperus, Anthuriums, &c., may therefore now be divided as wanted, potting the pieces separated singly and keeping them close until they have become established.

Moss Balls for Bedding Plants.—Most of our bedding plants, when potted off early in April, are each tied up roughly in a coating of Moss and then plunged out in frames, &c., in soil. The plants root into and through this Moss, and are very easily transplanted to their final positions in it without any injury whatever. The Moss is (of course) not disturbed in planting, the roots passing readily through it into the earth. We find this an excellent plan.—R.

Shading.—A house of any form facing the south, where the sun in the middle of the day comes directly upon the occupants, needs shading for a time on the sun-exposed side for almost any kind of plants; whereas, in the case of structures placed in the opposite direction, the bars and rafters break the force of the sunshine, and this, coupled with its striking them obliquely, much reduces the necessity for shading. Large numbers of tender-leaved, fine-foliaged plants, such as Cyanophyllums, Caladiums, Alocasias, Palms, and Ferns absolutely require shade when the sun is powerful, as otherwise, if the foliage be not positively burnt, it gets so brown as to make it unsightly. It is much the best plan to put those plants, both flowering and fine-leaved, that want shade, at one end of the house, using shade there only. It cannot be too often impressed upon beginners in the cultivation of plants that the blinds in all cases should be movable, and that they should never be down before there is absolute necessity for it, nor to fail in rolling them up as soon in the afternoons as they can be dispensed with. The material used should also not be thicker than just to break the force of the sun's rays.

Achimenes and Caladiums.—Achimenes for late blooming that have not been started should at once be put into heat. Those first started in pans will shortly be ready for placing in the pots or hanging baskets in which they are to be grown. For large houses there is nothing more effective than these plants in good-sized wire baskets suspended from the roof. For general purposes pots of small or medium size will be found the most useful. Their rapid growth necessitates a liberal supply of water through the growing season, for which reason see that the drainage is efficient. Any Caladiums not yet started should immediately be shaken out and repotted. These will be serviceable, retaining, as they do, their leaves fresh and in good condition through the autumn. If there be a deficiency of any kind when the young crowns have got 6 in. or 8 in. in length, they may be cut out from the tubers, placed singly in small pots, and treated as is usual in the case of cuttings, in which way they will shortly get established.

Common Pinks for Winter.—Anne Boleyn and the common white are desirable Pinks for winter flowering in pots. In the preparation of the plants an early start is half the battle; and to obtain this early start the cuttings or pipings must be taken from plants that have been forced. Any one who may wish to make a beginning should take up a few plants, pot them, and introduce them into a gentle moist warmth. The cuttings should be taken as soon as the new growth is in a fit condition for striking, which is when the young shoots begin to acquire just a little solidity or firmness at the base. They must be inserted under a hand-light or in a close frame, where just a little bottom-heat can be had. The cuttings must not be permitted to lie about exposed to the air whilst being prepared, as they are more susceptible of injury from this cause than most plants. As they are trimmed they should be placed in a pan or some other vessel containing water, till a sufficient number be prepared. If only a few are required, they may be rooted in pots or pans; but the first-named plan is the best, and produces the most vigorous plants. They must be shaded from bright sunshine and kept in a moist condition without too much saturation. A light sprinkling of water when the shading is removed on bright afternoons will be beneficial. Under such conditions the cuttings will soon root, when air should be given, gradually increasing its quantity till fully exposed. As soon as they are sufficiently hardened to bear full exposure, take them up carefully and plant them out in a prepared bed in an open situation, about 9 in. apart. A fresh loamy soil, slightly enriched with old cow manure, suits them best. The summer management, which will not involve much trouble, consists in maintaining a loose friable surface by frequent stirring, and watering occasionally in dry weather. Early in October the plants must

be carefully lifted, with balls, and all the root possible, and potted in 5-in. or 6-in. pots, putting the strongest in the larger size. Some of the strongest plants of Anne Boleyn may perhaps require pots a size larger, if the cuttings were obtained early. After potting, the plants may remain in the open air on a coal-ash bed for a time, but must not be exposed to severe frost. From the open air they should be taken to a cold pit, where they must remain till moved into a warm greenhouse to force them into bloom. The stronger and better established the plants, the better they will bloom when forced; but if started early, the forcing should begin gently, and the plants should occupy a light position. —H.

Pink Lady Blanche.—This is a free-blooming Pink, and one very valuable for forcing; it is easily grown and useful in the conservatory, as well as for cutting for bouquets, white flowers being always in request. The blooms, too, do not burst like those of other varieties. My mode of culture is as follows:—About the end of the present month, or as soon as there are plenty of cuttings, which there will be if the plants have been forced on in a little heat, I insert them in the same way as I do those of Verbenas; I plunge the pots in a gentle bottom-heat under a hand-light, or place a square of glass over the pot, shading them when the sun is very powerful; when well rooted, I gradually harden them off. About the end of April I plant them out about 10 in. apart in good soil, during the summer they will take care of themselves. About the middle of October they will require to be potted in 5-in. pots, and kept in a cold frame through the winter, or till they are required for forcing.—W.

Soil for Camellias.—It is frequently urged that Camellias require peat and other ingredients almost out of the reach of ordinary cultivators. That they will grow in peat we all know, but its quality varies so much that the majority of growers would do better, when making a bed or border for them, to form it as they would a Vine border, simply omitting all noxious rank manures, and relying on a top spit of an old pasture to supply nourishment. This would maintain a healthy growth longer than any kind of compost ever put together. A little dry cow or sheep manure, or sand if the soil be deficient in that respect, might be added with advantage. If at any time the plants need stimulating, liquid manure or a rich top-dressing keeps all going on satisfactorily. This is the best season for planting Camellias, and I would recommend any one having plants in an unsatisfactory condition to plant a portion of them out-of-doors, not under the shade or drip of trees, but where they would be subjected to moderate exposure, *i.e.*, where the force of cutting winds would be moderated by trees or shrubs or buildings. Our most flourishing beds of them are on Grass in openings in the Pinetum and pleasure-grounds, where dense specimen Conifers grow in luxuriance without shading them. Camellias out-of-doors, though perfectly hardy, will never supply the place of those under glass, as spring frosts are so liable to damage their flowers. Under glass they are the very best winter-flowering plants which we have. Their season of flowering, too, may be lengthened by having plants that mature their growth early and that begin to expand their blooms before winter sets in. Thus a continuous succession may be maintained all through the dull months until Roses are abundant.—G.

Gorse for Gooseberry Caterpillar.—For some years I have found that placing small pieces of gorse round the stems and in the hearts of Gooseberry trees effectually gets rid of caterpillars. It should be placed there fresh on their first appearance.

Destroying Ants.—Our conservatory was infested with ants last summer. I tried many of the Infallible Insect Destroyers, with little or no effect. I observed one day a dense column crawling up the window-frame; some of them were winged. It occurred to me that they might not like pepper, so while the gardener swept as many as he could into a pail of hot water, I gave the rest the benefit of the contents of the pepper-box. They retired quickly, and have not re-appeared.—E. B.

FRUIT.

Renovating Old Pear Trees.—The following may be interesting to some of your readers concerned in the treatment of old Pear trees that have become so cankered that they do no more than bear a few poor fruit at the extremity of the branches, and even if they make any young wood it dies almost as soon as the leaves fall. I had three or four such trees on a wall, covering at least 70 ft.; so, instead of taking them up and planting young ones, I had them cut back to within about 9 in. of the main stem, and on the portions left I grafted the Winter Nelis Pear, which took well. Although this was only done three years ago this spring, the walls are now well and regularly covered for from 4 ft. to 6 ft. on either side of the old trees with beautiful young wood; and last year, although a bad season for Pears, I picked about ten dozen fruit, possessing very fine flavour, and there is now a promise of a good crop. I this spring intend to graft another tree with a different sort of Pear, to see if it will answer equally well; but there is no finer Pear grown than the Winter Nelis, as it is a good and regular cropper, and a perfect dessert fruit, both as regards flavour and appearance. I have also put in buds in old trees, which have taken well, but they do not fruit so soon. In one case I put eight buds in one tree seven years ago; four of them came away well the first year, and have borne fruit for two seasons. Last spring another of these buds started, and made a shoot of about 3 ft. In the autumn the sixth bud started, and is now strong, although not more than 3 in. long; but I have no doubt it will grow well this year, and make up for lost time. Is not this an extraordinary case of buds lying dormant for a number of years before starting? In either grafting or budding old trees, I should recommend that the top branch on either side be left for the first year to draw the sap, or the stems will bleed so much that damage may be done to the grafts or buds.—E. D. S., in *Field*.

Mulching for Fruit Trees.—For many years past I have mulched fruit trees with the long manure as brought from the stables. In the matter of bush trees, such as Gooseberries and Currants, it serves two or three purposes: first, it manures the land; secondly, it keeps the fruit clean. The heavy summer rains, unless the trees are mulched, splash the fruit and make it useless. Peaches, Nectarines, and Apricots all share in this annual dressing, which, I believe, does much good and saves watering.—R.

Growing Strawberries.—Good Strawberries cannot be had without labour or space in which to grow them. The following is a plan which we have found to be most successful:—The earliest runners are selected and layered on pieces of turf let into the ground. As soon as they are well rooted they are severed from the parent plants and transferred to permanent quarters, on well-enriched and deeply-dug ground. They are planted in rows 2 ft. apart, and 1½ ft. asunder in the row. All the runners are kept pinched off during summer and autumn, and the following year they produce a few very fine fruit, but the second year they bear prodigiously, yielding fruit of the largest size and finest quality; the next year they deteriorate somewhat, and after fruiting a third time they are destroyed, thus necessitating successional beds; and, no matter how limited your space may be, you must resolve to have successional beds if you wish to have good fruit. We never yet saw fruit worth the name that had been grown year after year on the same plants and ground. The following are free-bearing kinds, hardy, and good, either for dessert or preserving—Vicomtesse Héricart de Thury, President, Sir Charles Napier, and Sir Joseph Paxton.—W.

Monstera deliciosa.

HINTS FOR AMATEURS.

Those who are fortunate enough to possess a little patch of garden in any suburban district should now be busy, morning and evening, sowing or planting. One of the most frequent of all questions asked by amateurs is, "How deep shall I sow my seed?" To this question we can only reply that it depends on the kind of seeds sown. The amateur must be guided, to some extent, by the size of his seeds; for example, Sunflowers, Sweet Peas, Convolvulus, and Nasturtiums have large seeds, and these will find their way through nearly any depth of soil; but the best depth to sow these is, say, 1 in. to 1½ in. deep. Now, if we were to bury some of the smaller and more tender of flower seeds 1 in. under the soil we should never see the young plants come through the surface, and it it possible that the seedsman would be blamed for supplying bad seeds, when in reality the fault was our own. All small dust-like seeds should be sown on the surface of finely-raked ground, and then just enough of finely-pulverised soil should be sprinkled over to cover them completely. Many seeds, as Mignonette, Larkspurs, Wallflowers, and many annuals, will grow well if simply thrown over the surface of newly-dug earth and then raked in with a small-toothed rake. The object in covering the seeds is two-fold, viz., to keep them moist and dark until germination takes place, and to hide them from the birds. Everywhere in Nature we see the seeds sown as soon as they are ripe, and the falling leaves cover them over and eventually supply the young plants with the best of all manure. For the generality of large seed ½ in. deep is quite enough, and this depth is best for all except the smallest or dust-like seeds. If the flower-garden and borders are to be gay with a variety of hardy annuals, now is the best time to sow them, and not a day must be lost. A dozen showy varieties will only cost a shilling, and these will add much interest to any little suburban or town garden, however small.

Now, it is, unfortunately, but too true that there are many amateurs who do not know the names of half the plants they admire in the

market, or in the gardens of their neighbours; so we will just name a selection of plants which will bloom during the ensuing summer if sown at the present time, and carefully watered every evening in dry weather. This latter operation will be an interesting one, as it will bring the amateur into close communion with his plants, and much will be learned as to their individual peculiarities and requirements. A garden is of little use to its possessor unless he takes a personal interest in its management, and in time this attention will grow into a pleasure; and no part of the day will be more pleasantly spent than an hour or two in the cool of the evening when the pet plants are being duly attended to. One of the easiest of all plants to grow, and one of the most deliciously-fragrant of all plants, is the common Mignonette, or "Little Darling," a name bestowed on it when first introduced into French gardens. We should like to see every bare inch of soil in all our parks, squares, and gardens covered with this "fragrant weed;" and one way of obtaining this is to buy an ounce or two of seed at the cost of a few halfpence. This should be emptied into one of your pockets, and then, on passing any bare spot, a pinch of seed might be sprinkled over it, and some are almost sure to grow; and they will perfume the evening air with their refreshing fragrance.

Most people like flowers, but they neglect their culture for the want of definite information how to proceed. Sweet Peas are showy and fragrant; their flowers being borne on long slender stalks makes them suitable for cut flowers, and they, moreover, last remarkably well in water. Convolvulus major, or "Morning Glory," is a handsome and quick-growing climber, and a few seeds of this should be pricked in close to any bare wall or fence, as it makes an excellent trellis-plant, or it can be trained up strings beside the door or window—positions in which its rich ruby, or purple-tinted flowers show to the best advantage. The common Canary Creeper is a general favourite, and grows well treated like the last. It has fresh green leaves, divided into about five lobes, its flowers being of a bright golden-yellow colour, not unlike little canary birds; hence its popular name. Growing up a string by the cottage porch, or scrambling over a low fence, this is one of the most beautiful of all climbing plants. Its botanical name is Tropæolum peregrinum, and it is nearly related to the common Nasturtium, another elegant and free-flowering climber, well known in nearly every cottage garden. Ten-week Stocks should now be sown in patches, and they will bloom in the course of a few months; while their flowers are nearly as sweet as Mignonette. Asters may be sown in the same manner, and hardly ever fail to produce their large richly-tinted double flowers. In addition to these, Larkspurs (purple and white), Snapdragons (Antirrhinum), Soapworts (Saponaria), and Clarkias should find a place along with Collinsia bicolor, Love-lies-Bleeding (Amaranthus), Candytuft (Iberis), Eschscholtzia californica, Lupins, Nemophila, and the rosy cushion Pinks (Silene pendula). The above will grow and flower freely in any ordinary garden soil, and are quite as well worth growing as Geraniums and other summer bedding plants; though, if possible, include both in your arrangement. As to the question of expense, any of the above seeds can be bought at any seed-shop in penny or two-penny packets; so that the cost is no serious obstacle to their culture. B.

Graveyard Gardens.—There are few open spaces either in town or country that present features more depressing than those found in cemeteries or country graveyards. A few sombre trees may be seen here and there, sometime planted with judgment, sometimes without, but generally of a heavy, funereal aspect; and nearly all the rest is a wilderness of mounds, headstones, pretentious tombs and monuments, much long rank Grass, and seldom any attempt to produce elements of beauty or of cheerfulness. The surfaces of all graves should be little gardens, surrounded by an edging of wirework or some other elegantly made material, and on each should be cultivated a few dwarf flowers, such as the taste of the surviving relatives might dictate or their circumstances enable them to obtain. Here at once are introduced elements of beauty and cheerfulness, and, not least, of cheapness, as the requisites may be obtained at a comparatively trivial cost, whilst the attention necessary in all future time may well be the duty of the graveyard attendant, who should receive a sufficient salary to enable him to keep his garden so neat and so pleasant as to make it at all times a loved resort of the living. Only one such a grave garden have I yet seen; it is in a humble churchyard, and is now all abloom with pretty spring flowers, Daisies, Primroses, Forget-me-nots. Hepaticas, and top-dressed over with fine Cocoa-nut fibre refuse, and enclosed with a low edging of wirework. To maintain the neatness is but a labour of love, and grave gardens will more fully than in any other way serve to perpetuate a sentiment for the dead, which should ever be that of fond remembrance.—A. D.

House and Window Gardening.

Periwinkles as Window Plants.—The pretty little blue-flowered Vinca minor, or Lesser Periwinkle, as it is called, is well worth cultivating in pots or baskets in windows. It grows and flowers freely in spring and summer, and its glossy-green leaves resist the dust and smoke bravely. There are variegated and double-flowered varieties of this Vinca which are also well worth growing either inside or outside of windows in town or country. Any garden soil with plenty of road or river sand added will suit the Vincas well, and if a little manure-water is given when they are growing freely it will greatly assist them.

The Lesser Periwinkle (Vinca minor).

Begonia manicata as a Window Plant.—I saw this flowering beautifully in a window at Sunbury the other day, in a sitting-room which seldom has a fire in it. The plants had been in the same position three months.—V.

Window Gardens.—Prepare boxes for window plants. If they are small they may possibly be accommodated indoors for two or three weeks prior to placing them outside, in which case the plants will get well established before they are subjected to outdoor treatment. The boxes, pots, or pans to be used for window plants should be perforated sufficiently to allow superfluous water to escape readily. A layer of potsherds, small chips of brick or sandstone, should be put in the bottom; then the roughest of the soil, filling up with the prepared compost. Good fresh loam mixed with leaf-mould or some well-decayed manure makes an excellent compost, capable of growing almost anything. Pelargoniums of different kinds, but particularly the green-leaved plain and zonal sorts, also the white variegated-leaved varieties, are all suitable for window decoration, as are also Lobelias, Heliotropes, Fuchsias, Tropæolums, Mignonette, and many other plants. Ivy and likewise Ivy-leaved Pelargoniums are excellent plants for this purpose. Succulents, such as the different kinds of Mesembryanthemum, are likewise very suitable for sunny windows; and Musk, Calceolarias, and similar plants for positions where they can be kept moist. The variegated Iris is one of the prettiest plants that can be grown for the ornamentation of a window, and its leaves remain a long time untarnished. Perennial hardy plants, with the exception of Creeping Jenny and one or two others, are but short-lived when so treated; but many annuals may be employed with advantage for windows, and when they have done blooming they can be pulled up and thrown away, thus making room for Pelargoniums and similar plants, which form a useful succession to them.

WINDOW PLANTS.

The usual position occupied by window plants in general is on the ledge, outside in the summer time, inside in the winter. In both cases it will be advisable to have some protection, so as to prevent the plants from toppling into the street on the one hand, or, on the other hand, on to the floor of the room. Any neat little fancy guard will do inside; but I would suggest for the outside a box made sufficiently wide to over-hang the window-sill by 2 in. or 3 in, and to be 6 in. deep. In this the pots might be set, and surrounded with sand or ashes, or, better still, with soil; and if the latter, then at each end a few seeds of climbing Nasturtium, or Convolvulus major, or both mixed together, may be set, and by adjusting a few strings, may be trained up the sides of the window and festooned across the top. Not only is this desirable result (and additional attraction to the room window) attained by adopting the box arrangement outside, but the pots, plunged in the cool material, will not require nearly so much water and attention as when exposed over their whole surface to the action of a blazing summer's sun, which must be the case on an unprotected window-ledge.

Ventilation is a necessity as well in winter as in summer; and though in newly-constructed houses the windows are usually made to open above as well as below, still in many of older date the lower sash only is movable; hence, when opened, the plants are placed in a draught. This is alike prejudicial to the health of plants and human beings, especially in winter. So, if the temperature outside is very cold, set your plants either on one side or on the floor, replacing them after you close the window; but if the air be mild you can close the door, throw the window well up (the higher the opening the less the draught), and leave the plants to enjoy the fresh breeze. Never put your plants on a high shelf, so as to be "out of the way" during night, as the higher their position the hotter is the atmosphere in which they have to exist; consequently the plant is robbed of its fluids by an unnatural evaporation. These remarks are especially applicable to rooms in which gas is used. Rather place your plants on the floor. During summer, if you cannot arrange for your plants outside on the window-ledge as previously suggested, it will not be much trouble to turn them out-of-doors every night, even if it is only into a backyard. The cool refreshing dew of heaven is, in the absence of rain, nature's great restorer of exhausted energies. Leaves exercise during the day their power of evaporating moisture; but they have likewise the power of absorbing moisture during the night. With the coolness then prevailing, the moisture becomes condensed on their surface and forms dew.

Plants in a room are sure to have their leaves coated over with a deposit of dust. Where the leaves are smooth, or I ought to say shiny, this may be readily removed by washing; but where the leaves are soft and covered with hairs, some injury is sure to be done, be the hand ever so gentle that applies the sponge. However, the injury will do less harm than the dirt incrusting the leaves; and as it is much easier to keep one's own face thoroughly clean by washing it every day, so with your plants, in a room especially where fires are in constant use, wash them often, say at least once a week, and before the leaves are dry, sprinkle them well with clean water. When you syringe your plant always lay it on its side; the water used in this process will not then run into the flower-pot. If it does, you may get your plant what is called "water-logged." In the summer-time a day's rain, gentle and continuous—nature's shower bath—will be more effectual than sponging and syringing, even by the most loving hands. So in summer never let your plants miss a genial shower. J. C. N

Arum Lilies.—The culture of this Arum is by no means difficult. It will even thrive amazingly in limited pot space; but the luxuriant growth that displays its finest features is best got out of richer soil, more space, and plenty of moisture. A group of this Arum

placed in a cool hall in front of a disused fireplace, and, fringed by a few dwarf-flowering plants, presents a marked effect in efforts at indoor decoration. Few plants, perhaps, at this time of the year would more fittingly associate with this Arum than strong, well-bloomed specimens of the Chinese Dielytra, one of the most handsome and graceful of all early spring plants; the pendulous growth of both foliage and flower would effectively support the drooping and noble foliage of the Arum, whilst the handsome white spathes project from the mass of luxuriant leaves with a grace that words fail fully to describe. Plants that are so nearly aquatic in habit are doubtless difficult customers to feed in accordance with their entire needs in an entrance hall, but the need might be met by placing the large pots in zinc pans; and further, in occasionally running a damp sponge over the leaves to keep them free from the dust that will inevitably rise in the best conducted house.—A.

Snails and Slugs.—Last year I found that the application of Little's Soluble Phenyle prevented the snails and slugs from attacking my plants: I cannot say whether it killed them or not. I give the result of some experiments. The solution was applied to eleven out of twelve Dahlias, and these were not touched; the twelfth was eaten by slugs. The tall White Lily is a favourite of these pests: where the solution was applied these were not touched; the others were eaten. The same may be said with respect to experiments with the Chrysanthemum, Pyrethrum, and other plants; and I consider that the application was a decided success. If, however, the solution was applied after a plant had been partially eaten it generally died. One tablespoonful of the soluble phenyle, measured by a medicine glass, was poured into a gallon watering-can, which was then filled with cold rain or spring water and the mixture stirred; it was then poured round the stem of each plant, covering a space contained within a circle of about 1 ft. in diameter. This was applied every Monday for a few weeks and then discontinued; but in weather when snails were likely to move a little was added for the sake of precaution.—G. W. O., *Teignmouth*.

When to Move Tree Pæonies.—I notice that these should never be transplanted except in the autumn. If transplanted at any other season they are apt to perish either during the summer or in the ensuing winter. It seems a pity that these beautiful plants should be so little grown. They are at once among the most showy and striking of all hardy plants. Specimens of them in the herbaceous borders and beds are very striking; but massing them among shrubs or as separate groups on lawns is still more striking and effective. As soon as their leaves fall in the autumn is the only safe season to divide or remove them.—T. F.

THE SHRUBBERY.

Aralia spinosa.—This handsome-foliaged shrub or dwarf tree deserves notice on account of its late blooming, and also for retaining its large compound leaves until autumn frosts warn it that winter is approaching. I consider it far superior to its near relation Dimorphanthus mandschuricus. This latter sheds its leaves a month or six weeks earlier than the former, which is, to my thinking, a faulty property in shrubs or trees that are planted for ornament. What should be encouraged in planting is the selection of plants that bloom late and do not drop their leaves early. Spring and summer flowering shrubs are plentiful enough. Aralia spinosa bears its huge panicled inflorescence on the points of its principal shoots of the current season's growth. It is seen to the best advantage on a sloping grassy bank.—B.

Sowing Gorse or Furze.—Land intended for Gorse seed should be prepared much in the same way as Turnip land, that is, deeply stirred and finely pulverised; it should also have a dressing of good lime compost or a little well-rotted manure where a quick growth is desired, though it is a plant that will eventually flourish even upon a poor soil. From the middle to the end of April about 4 lb. of good seed per acre may be either sown or lightly drilled in; this will be found sufficiently thick either for cover or for cutting as food for stock. Where Gorse is intended to form a hedge about 1 lb. of seed to the 100 lineal yards may be sown upon the top of a well-worked ditch bank. This plant is more permanent if it be not allowed to seed, and the best time for trimming it is directly after the flowers are shed, generally about the middle of June. During the severe weather of the past winter rabbits made in many places great havoc among the young Gorse of last year's sowing.—A. J.

Forsythia viridissima.—We are indebted to Mr. Stevens, of Weybridge, for cut flowers of early flowering shrubs, among which were sprays of this beautiful free-flowering

A Hardy Spring-flowering Shrub (Forsythia viridissima).

Forsythia, from which our engraving has been made. It is a perfectly hardy shrub, growing in any ordinary good soil, either in the open in the form of bushes or against a wall or fence. In March and April its shoots are laden with large bright yellow blossoms, which last for a long time, both on the plant or placed in water in a cut state.

Cement for Aquaria.—The "Polytechnisches Notizblatt" gives two receipts for a cement for joining glass, wood, and metal. The first consists of a mixture of equal parts of shellac and powered pumice-stone, to be used while warm; the second is obtained by melting ordinary brimstone in a ladle, and adding an equal proportion of powdered pumice-stone. The pumice-stone in both cases must be thoroughly dried before mixing, as it apt to absorb moisture from the air.—Q.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 12.—Potting Achimenes; sowing Autumn Giant and Walcheren Cauliflowers, Veitch's Protecting, Cooling's Matchless, Snow's Early White, and Dilcock's Bride Broccoli, also Red and White Cabbage; planting out frame-sown Lettuce and Cauliflower plants; sowing Cottager's Kale, Asparagus Kale; also following sorts of Broccoli, viz., Snow's Winter White, Leamington and Knight's Protecting; thinning out Carrots in frames, also thinning Lettuces, Radishes, and Turnips.

April 13.—Potting off tender annuals and Fuchsias; shifting all stove plants that require it into larger pots; also Chrysanthemums without stopping their shoots; sowing Mignonette on borders; also Cottager's Kale, Cocoa-nut Cabbage, White Cos, Alexandra and Neapolitan Cabbage Lettuces, Cucumbers, and Melons; planting Globe Artichokes and Lettuces from autumn-sown seedbuds; also planting a border of autumn-sown Cauliflower plants that have previously been pricked out; pricking out Celery in frames; also Sweet Basil, Marjoram, and Ice plants; putting Heaths into cold pits; picking dead flowers off Indian Azaleas and placing the plants in a warm greenhouse; getting bulbs that have been forced in pots and placing them under the protection of a wall out-of-doors; sowing a collection of Everlastings; pricking out Leeks, Chervil, and Borage; potting Caladiums, Balsams, and young Vines; earthing up Potatoes in frames; also putting a little earth over choice ones above ground.

April 14.—Putting Caladiums into 10 in. pots; shifting Tree Mignonette and young Vines; sowing Fulmer's French Beans, Salsafy, Scorzonera, Celery, and Radishes of different kinds; planting out Cerastium tomentosum and Strawberries; spawning Mushroom bed and afterwards firmly beating it down; pricking out first batch of Cinerarias, Primulas, and Herbaceous Calceolarias; Putting in cuttings of Begonia parviflora and Chrysanthemums; thinning autumn-sown Onions; sticking Peas and putting Narcissi in pots just coming into flower under wall out-of-doors, in order to prolong their blooming; sowing Radishes; also Giant White Cos and All the Year Round Lettuces; sticking Peas, and afterwards earthing them up a little; getting all bedding plants out under south walls, to harden as fast as they become fit for exposure; hoeing amongst all growing crops as fast as the weather will permit.

April 15.—Potting Cockscombs, Tuberoses, and Ten-week Stocks; sowing Scarlet Runners in rows 5 ft. apart, and more Mignonette out-of-doors; also Blue-branching Larkspurs; planting Dwarf Curled Borecole for seed, Carnations, Borage, and more Cauliflowers; transplanting spring-sown Onions, to fill up gaps in main bed where plants have failed to come up; pricking out seedling and double red Daisies; hoeing among Raspberry plantations; putting cases over two or three rows of Black Prince Strawberries that are coming into flower; stopping shoots of bedding Calceolarias, and tying up more Lettuces; sowing Scarlet Runners in deep trenches, so that they may be easily protected from frost; also Nasturtiums, Mignonette, Larkspurs, and Convolvulus; and likewise a collection of Antirrhinums; pricking out Lettuces, Celery, Asters, Stocks, and Tagetes; planting out spring-sown Cauliflower plants; also Giant White Cos and All the Year Round Lettuces.

April 16.—Potting Lobelia Paxtoni, Nepetas, and Chamæpeuce diacantha; shifting a few Palms into larger pots, and potting off Celosias and Prince's Feather; sowing Sweet Peas in pots, also Mignonette, Vegetable Marrows, Malope, another frame of Early Horn Carrots, and a border of French Beans; planting out forced Tulips and Lily of the Valley, second-sown Melons, and spring-sown Lettuces; putting in cuttings of Coleus, Ageratums, Salvias, and Gladiolus into cold frames; hoeing among spring-sown Onions; placing forced Roses under back wall, where they can be readily protected with mats in case of cold weather; putting a little soil on Asparagus beds; potting plants of Scented Verbenas, Tricolor Pelargoniums, and Tomatoes; giving Cucumbers a little top dressing, picking off all false blossoms, and stopping them where required.

April 17.—Potting Celosia pyramidalis, coccinea, and aurea; shaking out and re-potting large standard Heliotropes; sowing Nonpareil and Champion of England Peas, Broad Beans, Spinach, and Walcheren Cauliflower; planting Black Prince Strawberries, Gladiolus, Dielytra, and Sweet Briers; putting in Pink cuttings on hotbed; thinning Carrots in frame, also early-sown Turnips; potting off seedling Ageratums, Solanums, and Petunias, also Alternantheras, Coleus, Verbenas, Vegetable Marrows, and Ridge Cucumbers; hoeing between rows of Parsnips, Onions, and Carrots; weeding Box edgings, and cleaning up kitchen garden.

Flower Garden.

The charm of a garden is the constantly-recurring freshness which the various plants present at all seasons. Common Violets, red and white Daisies, Crocuses, Primroses, Anemone apennina, Arabis albida, and Scilla sibirica will soon be in flower; and these will very shortly be supplemented by Omphalodes verna, Irises, Candytufts, Hepaticas, Gentians, and others. All of these should be plentiful in every garden. Expense as regards these plants need be no barrier, as they can all be had for a few pence each, and can be transplanted at almost any season. The denser Sedums and Saxifrages are appropriate plants for association with the foregoing, either as undergrowth or as intermediate patches. The following are now very beautiful, viz.—Sedum aureum, S. acre elegans, S. glaucum, and S. lydium, Saxifraga rosularis, S. hirta, and Thymus hirsutus. The smallest plant of any of these, split up and propagated during the summer, would make several good patches for

next spring time. Lily of the Valley is now starting into vigorous growth, and its flowers will be much improved if the inert surface soil be removed and replaced with fresh loam and well-rotted manure in equal proportions. Beds of Dielytra spectabilis and Spiræa japonica should be treated in the same way, but it will be necessary to protect these in the event of sharp frost occurring. Mats laid on hooped sticks form the simplest protection for them and other spring flowers of doubtful hardiness. Where spring gardening is not practised, and the beds at liberty, a good deal may now be done to advance the summer bedding and prevent a pressure of work at that inevitably busy season. The arrangements can be completed, the designs marked out, and the hardy and half-hardy plants may be at once planted. Edgings, divisional lines, and groundworks of Violas, Echeverias, Sempervivums, Saxifrages, Sedums, Menthas, &c., can all now be planted with safety, and very shortly Calceolarias and Verbenas may follow. Autumn-sown annuals may now be thinned out; the plants are sturdier and flower better than if left too thick. Sow in the open ground Sweet Peas, Mignonette, Candytufts, Eschscholtzias, Larkspurs, and Clarkias, and prick out those sown in frames as soon as they are fit to handle. Bedding plants have driven annuals for summer embellishment out of our flower gardens; and though this is to be regretted it cannot be wondered at, seeing that bedding plants are so much more lasting and amenable to manipulation. Still, there is room for both in most gardens—the bedding plants for the parterre, and the annuals for the mixed borders, supplementary to the herbaceous plants, a purpose for which they are every way adapted. Shrub planting, pruning, hedge clipping, and all other extraneous work, should now be completed, as each week will bring its own work that must be done, such as mowing and rolling lawns, sweeping, weeding, and rolling walks, and planting out bedding plants.

Auriculas.—Exhibitors of these will now have an anxious time of it, as all the trusses of flowers are showing themselves; and the question arises as to whether certain flowers will be in perfection at the time required. No definite instructions on this point can be laid down for those who have not had experience in such matters; suffice it to say, however, that, as a rule, selfs are in good condition early, and that they do not stand so well as the best green, grey, or white-edged flowers. There are exceptions, however, as one of the latest Auriculas to flower is Duke of Argyll, a fine crimson self; and some of the edged flowers lose their character in a few days after the zenith of their beauty has been reached. If it be intended to push forward any late trusses, the plants may be placed in a warm house, near the glass, and air must be admitted rather freely by day, with a little at night. The Auricula shows are fast approaching, and as many growers at long distances off may want to exhibit, but are deterred from doing so owing to the expense, we may mention that if such persons would turn the plants out of their pots, and wrap the balls round with old shading tightly, they might be packed into very small boxes. We have, indeed, seen an exhibitor carrying a box in each hand, in each of which there were thirty plants—as many as most amateurs would be able to exhibit. The societies provide pots and Moss for surfacing them.

Carnations and Picotees.—Look over the plants and remove decayed leaves; also weeds, which will be sure to grow in the fresh compost. Keep all tender sorts under the protection of cold frames as long as it is convenient to do so. If cuttings of perpetual-flowering Carnations have not yet been put in, no time ought to be lost in seeing that this is done. Those who are desirous of having a large stock of plants should put in the small side growths as soon as they are large enough for that purpose. If these be placed under a close glass light in the propagating house, not 5 per cent. will fail to strike root. Cuttings put in early and now well rooted should be potted off singly in small pots, setting the pots in a warm, rather close place, to induce the formation of fresh roots; afterwards place them in a cold frame.

Hollyhocks.—Seeds from the best sorts may now be sown in the open air if there be no glass lights or frames available, but they will germinate more freely in a gentle hotbed, although they must not be coddled under glass after they are above ground. Plants raised in this way will flower well next year. See that no time is lost in getting all named sorts planted out, using the precautions previously recommended.

Pansies.—These are even more deserving of attention than the Hollyhock, as they are attacked by no disease that cannot easily be combated. Plants in pots are now making a charming display, and if the leaves have been kept free from mildew and green fly, a continuation of fine flowers may be expected. When the flowers begin to fall off in quantity, as they will do in time, pick all of them off, surface-dress with rich soil, and on this peg the shoots down; this will produce renewed vigour, and perfect flowers will be the result.

Hardy Primulas,—Sparrows are very destructive to these when planted outdoors. We have hundreds of Primroses and Polyanthuses planted out, and it is disheartening to see the flower buds picked off and dropped on the ground in thousands before they open. Grown in cold frames, the finer forms of Primrose rival even the Auricula and laced Polyanthus. They require but little attention, but that must not be denied them; they must have free ventilation, plenty of water, and the leaves kept free from red spider and green fly. Plants of P. nivalis are now masses of bloom, which is admired by every one. We place the plants under a north wall when they go out of flower, and they make free, healthy growth.

Annuals, &c., as Substitutes for Bedding Plants.—Although annuals do not, as a rule, last long in flower, there are some which may worthily rank with bedding plants, and amongst these may be mentioned the following:—Asters, Balsams, Helichrysums, Nasturtiums, Ten-week Stocks, Phlox Drummondi, Portulacas, Tagetes, Sanvitalias, and Zinnias, as flowering plants, and Beets, Amaranthuses, Perilla, Artemisias, Tobacco, Ice-plants, Solanums, Ricinus, and Salvia argentea as fine foliage plants. There are also a few perennials, biennials, and annuals which may be raised from seed, but which are usually struck from cuttings in order to preserve some special character, viz., Ageratums, Verbenas, Lobelias, Petunias, Cannas, Chamæpeuce, and Pyrethrums; all these are beautiful as regards either foliage or flowers, and, if carefully used, may be induced to produce a display almost equal to that yielded by our most favoured bedding plants. With the exception of Sanvitalia and Beets, the whole may be raised in pots on a slight bottom heat, and as soon as they are fairly out of the ground they should be placed in a greenhouse for a few days to harden off. A cold frame having been prepared with rich soil, the flowering section—with the exception of Ageratums, Balsams, Lobelias, Petunias, Phloxes, Portulacas, and Verbenas, which should be pricked off in pots and kept in moderate heat close to the glass—should be pricked off about 3 in. or 4 in. apart. The whole of the fine-foliaged section should be put into pots, pans, or boxes, and retained in heat. A knowledge of the heights and colours only is then required to make a grand display. A moist, warm day should, if possible, be chosen to put them in the open ground, and if taken up with balls of earth they will be sure to succeed. Sanvitalia and Beets may be sown where they are required to stand and thinned out where necessary. Pyrethrums, Petunias, Lobelias, Ageratums, Cannas, and Chamæpeuce should, to have them in good condition, be sown as early as possible.

Glasshouses.

Cyclamens done flowering should at once be placed in a house or pit where the atmosphere can be kept a little close, with plenty of light, but slightly shaded from the sun; these are also liable through the spring months to get infested with green fly and red spider, which, confining themselves almost exclusively to the undersides of the leaves, frequently go unobserved until the foliage is very much injured, the result of which is that it dwindles away through the summer, and the roots get into a stunted, hard state, which prevents their afterwards growing and flowering satisfactorily. Where means exist, and the hints that have been given are followed for keeping back a few of the latest-flowering kinds of Camellias, these will be found very useful in the conservatory during this month along with Epacrises, Boronias, Eriostemons, Azaleas, Rhododendrons, the last batch of Hyacinths, Tulips, Lily of the Valley, forced Roses, Cinerarias, &c. As the sun's power increases, there will be still more need for attending to shading, or the flowers of most plants will be of comparatively short duration.

Climbers that were cut back during the winter, and that have now commenced growth, must have regular attention in the way of training. Those possessing a twining habit require constant care in this matter, otherwise the shoots get interlaced to such an extent that it is impossible afterwards to get them disentangled, and the young growth of all such plants as these is generally so tender as to scarcely admit of being untwined from anything that it lays hold of without stopping further extension. Plants of this description, either grown in pots, tubs, or planted out in borders, where the root space is limited, will, in most cases, require the assistance of manure water. It is, however, of little use applying this unless growth is actually in progress; for, if given at other times, the fertilising elements which it contains get washed away by the usual waterings, and do no good. In structures of this description the use of ordinary manure water is not admissible, from its offensive odour, but if made from guano, with a little soot, and applied early in the morning, that objection will be obviated; and in places where nothing of the kind can be employed Clay's or Standen's manure dusted on the surface of the pots, tubs, or beds, where it gets washed into the soil with the ordinary waterings, will be found most effectual.

Tuberous-rooted Begonias.—A stock of these should be grown in all places, large or small, on account of their being so useful in many ways. Roots of them started some time ago will now have made some progress, and should be furnished with root-room proportionate to the size of the bulbs. They will thrive under ordinary greenhouse temperature, but will come on faster if kept a little warmer. Any remaining bulbs that may yet be in a dry state should immediately be started; they will come into flower later in the season.

Calceolarias.—The herbaceous varieties will now be growing apace, and should be well attended to with manure-water; they are gross feeders, and the advancing flower-spikes will be much benefited by it. They should be kept in a temperature of 45° at night. There are no plants that require more care as to keeping them free from aphides, for if these be once allowed to get ahead it takes a severer application of Tobacco to kill them than the blooms will bear. The shrubby kinds are equally deserving of cultivation as the softer sorts, although their flowers may not be so conspicuous. There are few more useful subjects for general decoration than the old C. aurea floribunda. It is serviceable in the shape of small plants, such as are grown for the London market; but so managed it is insignificant compared with the character which it assumes when grown on for years and regularly cut back each season after flowering, something like a Pelargonium, part of the soil being removed, and the plant repotted similarly. Any of the stout-habited, dark-flowered kinds are suitable for growing in the same way. The treatment which they want at this time of the year is such as that which answers for the herbaceous sorts.

Cinerarias and Primulas.—Those who intend to save seeds of these should select the best marked forms as seed bearers. In the case of the Primulas they should be set on a dry, airy shelf, where they will get plenty of light, choosing plants that have not been weakened through early flowering, as they will not produce nearly so much seed as those that have only bloomed recently. With Cinerarias it is necessary to keep the colours separate. Put the best forms and colours of red, and also of blue, as well as the white grounds with red tips, each by themselves in small frames from the time they come into flower, selecting for the purpose the latest bloomers. Thus treated, these three colours will produce plenty of variety, including the many shades of purple and violet; but only by keeping them apart can a preponderance of the blues and purples of different shades be avoided. A

little more Cineraria seed may again be sown towards the end of the month, and the plants from the first sowing must be treated so as to prevent their being drawn up weakly. A little Primula seed should also be sown to come into flower before Christmas. Double Primulas may now be propagated by means of cuttings kept a little warm, but not so much confined, or they are liable to damp. They are not nearly so effective for decorative purposes as the single varieties, but where flowers are much in request for cutting the double kinds are a great deal the best, as they last longer than the single ones.

Kitchen Garden.

An additional supply of Broad Beans and more Peas should now be sown. Of the latter, if Champion of England, Veitch's Perfection, and one of the tall varieties, such as Emperor of the Marrows or British Queen, are all put in at once, a successional crop will be obtained. Unless where the land is wet, Peas at this and subsequent sowings should be sown in shallow trenches, so that the soil covering the seed should be about 1 in. below the surface level on each side; this will admit of the liberal application of water, which in dry weather is necessary to them. To further assist them a quantity of manure should be worked in deeply at the bottom of the trenches. Do not sow too thickly. At this and the succeeding sowings half the quantity of seed required earlier, or when there was more to fear from the depredations of slugs and birds, will now suffice. More Spinach should be put in between the rows of Peas or any vacant spaces, and a little more Turnip seed, if required, should also be sown. Of Seakale, if a sufficient quantity of roots be not at hand for planting, seed may now be sown, making holes with a dibber, and covering it with 1 in. of soil. Drop three or four seeds in each hole, which should be 1½ ft. apart in the row, with a similar space between the rows, these distances asunder being best suited to the proper development of plants of this description.

There are no edgings to walks that equal Box in appearance, when well kept. The present is a good time for either replanting or making up any deficiencies that may exist through the Box having died in places. The latter mishap generally occurs where the land is of a heavy, wet, retentive nature, and insufficiently drained; or it is killed through vegetable crops being planted too near it. If the haulms of Potatoes overhang it during the summer, or if Cabbages, Beet, or anything of similar character be too close, it gets killed. Where any considerable portion of the Box is dead it is much better to take up the whole and replant, as where the dead portions are simply replaced it has a patchy look. In the case of existing edgings in the usual positions—viz., bounding gravel walks—that require to be thus treated, remove all the gravel from the sides, placing it in a ridge in the middle of the walk; take up the whole of the Box, which should be heeled in to prevent the roots drying until the ground is prepared; commence at one end and dig over where the Box has stood and is to be replanted, about 1½ ft. or 2 ft. in width, breaking the soil fine.

Care must be taken to have the surface thus dug of the right height, proportionate to the ground which the edging is to enclose; if too high it will have an awkward appearance, and if too low it gets smothered through the rains washing the soil down upon it. Draw the line from end to end, quite straight or gradually curved as the course of the walk requires; with a spade open a trench, cutting straight down so as to have it perpendicular on the off-side, drawing the soil inwards; this trench should be the full depth of the spade. Then commence with the Box, dividing it by hand; it will slip up readily, and care must be used to secure a portion of roots to all that has to be planted. Begin planting it in a thin continuous line, with the tops about 2½ in. or 3 in. above the surface, filling in the trench as the work proceeds with the soil that was taken out to form it, treading it with the feet solid so as to make it lie quite close. After the planting on both sides of the walk is done, replace the gravel, adding more if required. A little practice will enable the operator to plant the Box in a continuous even line, all equal in height and breath. All the subsequent attention necessary for some time will be in the matter of watering the Box in May or June if the weather be very dry.

VEGETABLES.

Substitutes for Spinach.—In gardens where Spinach in summer quickly runs to seed, a trustworthy substitute often saves trouble and annoyance. The Perpetual Spinach, or Spinach Beet, as it is sometimes called, may always be relied upon, no matter how hot and dry the weather may be. It does not possess the peculiar sooty flavour of the true Spinach, and it is hardly so dark in colour, but otherwise it is a most wholesome vegetable, and is exceedingly prolific, and one sowing will last the year. Sow about this time in drills 1½ in. deep and 1½ ft. apart. When the young plants appear, thin gradually, using the young succulent leaves, until finally they are left 8 in. or 9 in. apart in the rows, and afterwards the leaves should be gathered in the same way as Spinach. The Spinach Beet is a biennial, and will not flower till May or June of the following year. It is much sought after in some parts of the country, and used with Parsley and Thyme for stuffing salt meat. For summer use only, the New Zealand Spinach is invaluable. It is a half-hardy annual, and, to have it early, should be sown in March, or early in April, in a hotbed. As it does not transplant well, it will be better to sow it in small pots, two or three seeds in a pot; harden off, and plant out in a sunny spot, 3 ft. or so apart, in May, towards the latter end of the month. It may be sown in the border at once, but will not be ready for gathering so early. It is very productive. Two dozen plants will supply a large family, as, when once well established, it grows with great rapidity, especially if it can have a good soaking of manure water occasionally. It will grow on the hottest and sunniest spots, but the leaves are larger and more succulent when well fed. Lee's Giant Orach may be usefully employed as a substitute for Spinach. It should be sown now in good deep land, and be thinned to at least 1½ ft. apart. —H.

Late Celery.—To have Celery as late as possible without "bolting," the sowing should not take place before April 20, and from that time, whether sown in a frame or on a prepared bed in the open air, it should be grown without checks either from loss of roots in transplanting, or from drought through being insufficiently supplied with water. When the young plants appear thin them out by removing a few at a time, gradually giving them more room as they require it, until they finally stand 2 in. apart, and then (if not already done) prepare the trenches, and before the plants rob each other too much, lift them carefully and plant them in the trenches. Well water and shade them, taking the shading off in the evenings, and replacing it on bright days as long as the plants need it. The planting should be done either early in the morning or late in the evening, or else during a dull day. The soil should never be allowed to become dust-dry. Celery is a marsh plant, and although it may not bolt much before its time if kept too dry, yet there are evils almost as bad as bolting, such as soft pithy stalks, which are mainly the result of checks improperly given. I have at different times grown a good many kinds—so called—but for late use I do not at present know any better than Clarke's Solid Red and Sulham Prize Pink. —E. H.

Staking and General Culture of Peas.—Peas should always be staked before they produce tendrils; besides, the stakes afford them considerable shelter and encourage growth. The rows should be slightly earthed up first, and if ordinary Pea-sticks are used they should be as tall as the Peas are likely to grow. To save expense and trouble in making the stakes, I always use the best of last year's stakes for the early Peas; their bottoms being decayed, they are chopped off, and they are then just tall enough for the earlies and second earlies, which are mostly of a dwarfer habit than late Peas. The lengths most needed are 3 ft., 5 ft., and 7 ft. Where sticks cannot be had conveniently, strong sheep nets stretched along each side of the row, and supported here and there by stout stakes, are an excellent substitute. As regards culture, except keeping the ground clean and stirred between the rows, the Pea wants little attention after staking. In dry seasons, a good thick mulching of rotten manure, litter, or short Grass, spread along the rows on each side, and about 2 ft. out from the stakes, is highly advantageous—not only improving, as it does, the quality and abundance of the crop, but also prolonging it very considerably. Mulching reduces the necessity of watering very much, but water may be given whenever there is time to apply it; there is no danger of over-watering, for the Pea absorbs an enormous amount of moisture from the ground, which is usually dry in the vicinity of the row. In gathering, the most forward should be diligently sought for, as when the pods are allowed to get old, growth soon ceases and the supply soon comes to an end.—J.

ROSES.

PLANTS FOR INTERMIXING WITH ROSES.

Roses are unsurpassed in their attractions by any flowering plants in cultivation when in bloom, but they have an uninviting appearance when their principal display for the season is over, which is not compensated for by the limited number of flowers which even the most continuous bloomers among the Hybrid Perpetuals, assisted by the Chinese and Noisette varieties, produce. This, of course, is not apparent in the case of such plants as are introduced into mixed borders, where the rusty condition which their foliage assumes in the after part of summer is not so prominently noticeable as when they occupy beds or borders by themselves. But to do full justice to Roses they require such liberal applications of manure as will not agree with the majority of flowering subjects; yet much may be done to render Rose-beds and borders attractive from early in spring up to the end of autumn without in any interfering with the flowering or general well-being of the Roses. In the selection of such plants as are adapted for this purpose it is necessary to consider not only the habit and form of the subjects chosen generally, but it is of equal importance that they are such as either possess an immunity from the principal insects with which Roses are so much infested, or that are easily kept clear from their depredations.

Perennials Suitable for Mixing with Roses.—In beds of Roses, where the plants were pegged down, I have found nothing more effective than the common White Lily (Lilium candidum) and the different varieties of L. canadense, three or four bulbs planted together in the openings between the Roses. They are equally suitable for using in this way amongst half or full-sized standards, but when associated with these the Roses should not be planted very close, or the Lilies are liable to be in the way of any one moving amongst them for the purpose of attending to their requirements. To follow these, Gladioli are in every way adapted as to the time they will come into flower, succeeding, as they do, both the Roses themselves and the Lilies (should they be used as well); and, like them, their erect, non-spreading habit of growth and the ease with which green fly can be destroyed by syringing, should it get from the Roses to them, adapts them well for growing in this way. Gladioli for the purpose should now be planted; the Lilies when the tops have died down. Single plants of Campanula pyramidalis, at intervals in the spaces between the rows of Roses, are also very effective. These should be raised from seeds sown in May out-of-doors in the open ground, and grown on through the summer; they should then be taken up, potted singly, wintered in frames, and planted out amongst the Roses in May.

Annuals for Mixing with Roses.—The best of these that I have found adapted for the purpose are Ten-week Stocks, sown about the middle of April, and again at the end of the month, grown on three or four plants together for a time, in 4-in. or 5-in. pots, and then planted out without disturbing their roots. The rich condition of the soil necessary for the Roses keeps the Stocks growing and flowering longer than under ordinary treatment. French and African Marigolds are especially suitable for this purpose. They keep on flowering long, grow freely, and are proof against aphides or other insects, as far as I have ever observed. These

should be sown at once, a few seeds each in a 5-in. pot, and planted out about the middle of May. Mignonette, either sown now in pots and afterwards transferred to the Rose beds, or sown at once where it is to remain, will, by keeping the plants thin enough, continue flowering till near autumn.

Protecting Rose Cuttings.—I find a slight covering of dry Fern to be an excellent protection for Rose cuttings and dwarf Roses when the buds are expanding, and until the young shoots get from ½ in. to 1 in. long. The frost comes and blackens them when unprotected, and in the case of cuttings, they have not the vitality to start again.—R. G. B.

NOTES ON HARDY FLOWERS.

Asters.—No time should now be lost in getting these sown, for the quicker the seed is sown the stronger will be the plants at planting-out time at the end of May.

Annuals.—Now is a good time to sow these. Many annuals are spoilt by being sown thickly on a hard, unbroken surface. If cultivators would only sow a great many of their annuals (at least, the hardiest among them) in autumn, to stand the winter, they would have them very much finer in spring and early summer than they are when sown in April and May. During the winter they root well into the soil; they make a good growth in spring, and come into bloom gradually, freely, and continuously. In early summer dry warm weather brings the plants into flower before they have made their growth, and they are soon over. Those who sow now should stir deeply, use some fine rich soil, and press the whole firmly down. All strong-growing annuals, such as Nasturtiums, Sweet Peas, Convolvulus major, Eschscholtzias, Malope, Lupines, &c., cannot be expected to flourish unless they are growing in a rich holding soil.

Auriculas.—These are fast coming into bloom, and will need abundant supplies of water during dry weather. On no account should the plants be sprinkled overhead, or the water will damage the expanding flowers. We are keeping our plants somewhat close, but fully exposed to light, and they are making a fine growth and throwing up bold trusses. As pot plants the alpine varieties are very beautiful; but in order to have the edging as pure and well defined as possible, they should be grown in poor soil.

Primulas.—These are now very beautiful, especially such kinds as P. nivea. P. ciliata intermedia, P. denticulata, P. pulcherrima, P. purpurea, P. amœna and its varieties, P. marginata, and others; and being on the whole easily cultivated, they should be grown by every one who is fond of hardy flowers.

Double Daisies.—These are now very attractive, and as there are several varieties in cultivation, an interesting collection may soon be formed. Such varieties as Early Gem, Blood Red, Common Red, Giant White, White Globe, Pink Queen, and Pink Beauty make a charming collection. Then it is a pleasing operation to raise some from seed, provided the latter be good. It should be sown now in a shallow box or bed in a cold frame, pricking out the young seedlings when large enough to handle, and in autumn finally planting them out in beds to bloom in spring.

Hyacinths.—Those in pots are now going out of bloom, and many are puzzled to know what to do with them. My plan is to plant them out under the protection of a wall in an out-of-the-way place where they can remain for years. A good deep trench is dug, and the plants are turned out of their pots, and planted in it, pressing the soil firmly about them. From bulbs treated in this way, many a posy of fragrant blooms may be cut in early spring.

Pansies.—Seedlings are now fast opening their flowers, and every day something new will be produced; the best should, therefore, be lifted and re-planted in prepared beds for summer decoration, and the inferior ones may be thrown away. I have planted some of the best-named varieties, both show and fancy kinds, out in beds, and they are growing freely. It is a good plan to peg the shoots firmly to the soil, in order to keep them from wind-waving. If anyone wishes to have the rich-belted white-yellow ground and self-coloured Pansies in full beauty, they should grow the plants in 4½ in. and 6 in. pots, in cold frames, and when coming into bloom, water them with liquid manure. This is how the fine Pansies seen at the exhibitions years ago used to be grown.

Pyrethrums and Ranunculuses.—Double varieties of Pyrethrums, planted out to flower in beds or borders, will now need looking after, as slugs are apt to eat their young growths. Ranunculses must now be encouraged to make all the growth possible, the bulbs having been planted late this spring, owing to the wetness of the season. Many fine Ranunculuses are lost through excessive moisture; therefore it is well to cover the beds during the heavy rains early in spring, before growth commences.

Tulips.—Beds of Tulips need all the light and air possible while the weather is mild. At this time of year the great danger of Tulips is a sharp frost following a heavy rainfall. On this account growers of choice varieties keep a covering on their beds, which can be lifted so as to fully expose the beds, or dropped to cover them, as may be necessary. D.

TULIPS.

THE Duc Van Thol Tulip, well known by florists for its earliness and adaptability for forcing, is a species altogether distinct from the garden Tulip (Tulipa gesneriana), from which so many varieties have been obtained. What are

The early Duc Van Thol Tulip (Tulipa suaveolens).

termed the species of Tulips are always considered more hardy than the Tulips sold by florists; and, moreover, if the species are well planted in the first place, they will improve in vigour yearly if left in the ground undisturbed, whilst the garden varieties of Tulips will greatly deteriorate.

Greig's Tulip (Tulipa Greigi) is a handsome and as yet rather rare early-blooming Tulip. It is a native of Turkestan, whence it was sent by Russian collectors to the Botanical Gardens at St. Petersburg two or three years ago. Of all the known species of Tulip—and there are some twenty-six—this is perhaps the most showy and desirable as a garden plant. It blooms freely in April or May, its large goblet-shaped flowers being generally of a vivid orange-scarlet colour; but there are also purple and yellow-flowered forms of this Tulip. Herr Max Leichtlin, of Baden-Baden, by whom the plant was introduced into commerce, tells us that its bulbs are so extremely hardy that they will withstand freezing and thawing with impunity, and that even when the leaves are half-grown they will endure a temperature as low as that of zero without any protection. The plant is a vigorous grower, attaining a height of from 9 in. to 15 in., and bearing flowers from 4 in. to 6 in. in diameter when fully expanded, and three or four lance-shaped glaucous leaves, with undulated margins, the whole of the upper surface being boldly blotched with purple or chocolate-brown. We have seen it growing well in Mr. Ware's Nursery at Tottenham.

Sowing Sweet Peas.—Everyone who has a garden should have a row or two of Sweet Peas. If sown at once (not too thickly) on deeply cultivated land, they will continue to furnish successional crops of bloom throughout the whole season, and the more the expanded flowers are gathered, the more lasting and satisfactory will be the results, as if allowed to mature seed-pods the plants become quickly exhausted. Sweet Peas may now be had in many distinct colours, but a good mixture will usually yield the best results. I generally drop a few seeds of Convolvulus major in the rows, and these late in autumn form beautiful objects.—J. G.

Variegated Jacob's Ladder (Polemonium cœruleum variegatum).—In some soils and situations this plant is apt to get rusty-looking, and in hot summer weather ceases to grow. A good way to prevent this is to plant it in its permanent position in April, keeping the roots well down in the cool soil, with which should be incorporated a little fresh cow manure. We treated some thus last year and they grew remarkably well—much better than usual. We propagate it by means of offsets taken off about the end of September, dibbing them in 3 in. apart in light sandy soil in ground Vineries or hand-lights, and keeping them close for a few weeks till rooted. There they remain until spring. If the weather is very severe we protect them with a mat or a little dry litter. Like most hardy plants used for bedding purposes, this variety of Polemonium dislikes fire-heat and coddling; simple treatment is best. We find that it associates well with plants having pale blue flowers. We have some forming centres to small circles of Blue King Lobelia resting on a groundwork of Mesembryanthemum variegatum. —H. J. C.

The Double Scarlet Geum.—I had this in flower all the autumn. The flowers were of good size, and as double as those of a good double Geranium, which they much resemble. They are of a deep rich scarlet hue, and, having long stems, are invaluable for bouquets. Now is the time to plant.—D.

Primula denticulata and Veronica Blue Gem.—This Primula is just now in its first flush of beauty; its round heads of lavender blossom and stems thickly powdered with yellow dust are perfectly delightful. Too much cannot be said in praise of Veronica Blue Gem; though for a short time frost cut the flowers, it is now again opening fresh blossoms, and makes, with Snowdrops, Crocuses, and lingering Arbutus berries, quite a glow of colour.—E. E.

Daffodils on Grass. — Conspicuous amongst hardy spring-blooming plants capable of defying the withering influence of an English March stand the Daffodils, the bright yellow flowers of which bend but do not break before the gales that sweep across our meadows. In this district the latter are just now quite yellow with them, large breadths having been allowed to grow undisturbed for years, as, beyond some of the flowers being gathered for indoor decoration by those who have no means of procuring forced exotics for such purposes, the plants are allowed to mature their foliage, as neither cattle nor game ever molest them. Where it is desirable to naturalise Daffodils, good bulbs of them should be procured as early after their foliage has disappeared as possible, and planted in clumps on banks or in semi-wild portions of the grounds where the mowing machine is not an early visitor. Under such conditions they will give unfailing satisfaction.—J. G., *Suffolk*.

Blue Spiderwort.—On p. 40 (March 27) of GARDENING, in a note signed "Lewis W.," Commelyna is called Blue Spiderwort. I beg to inform "Lewis W." that the blue Spiderwort is dark blue, and quite a different plant from Commelyna cœlestis, which is called the Commeline. There is also a white Spiderwort, and the roots and leaves of the Commelyna and Spiderwort are very different. The Commelyna should be treated like the Dahlia, and the tuberous roots lifted every autumn. The Spiderwort is perfectly hardy, and should not be moved at all.—J. M. L. [Commelyna cœlestis is the blue Spiderwort. The plant "J. M. L." alludes to is the Virginian Spiderwort (Tradescantia virginica) of which there are several varieties, some having double lilac, single blue, lilac, and white flowers. Both the Commelyna and Tradescantia belong to the Spiderworts and to the the order Commelynaceæ. It is not necessary to take up the roots of Commelyna cœlestis during winter unless the soil is wet and cold. It is a hardy plant.—ED.

ANSWERS TO QUERIES.

1786.—Soil for Hardy Lady's-slipper.—We should prefer a mixture of good fibrous peat and turfy loam, sifting out all dusty particles and covering the surface with Sphagnum, which encourages the formation of surface-roots, which are really the life of this family of plants. In the case of arietinum and pubescens we would recommend quite two-thirds of peat, mixing with the compost a little crushed charcoal. It is better to employ a compost which, if somewhat poor, is not liable to become sour, as any deficiency of nutriment in the soil may be compensated for by occasional waterings with weak liquid manure when the plants are in full growth.—J. C. B.

1788.—Old-fashioned Flowers.—From the fact of the roots becoming exposed, it would appear that the soil lacks solidity; and to this cause may be attributed the failure of the plants. If the natural staple is of a light, porous, or gravelly nature, it should receive an addition of good loam, marl, or road-scrapings; for although such things as Primroses often grow naturally in light vegetable mould, the roots generally enjoy an extended and somewhat deep root-run, and are, in addition, sheltered by an over-hanging vegetation. To grow them, therefore, successfully in the open the soil at the least must be made firm around them, and a good mulch of leaf-mould or manure should be applied early in the year. If the soil is very light, tread it down hard before planting. It may be also that the soil has become sour and unfit for the roots to work in, in which case it should be turned over, and thoroughly sweetened before planting, mixing a little manure with it. Pansies require a rich and friable soil; cuttings taken off now, and kept growing for a time in a sheltered situation, may be planted out permanently towards the close of the summer. Seed may also be sown from now up to August.—J. C.

1784.—Chrysanthemums for Show.—It is too late to think of striking Chrysanthemum cuttings for the formation of large specimens. If you particularly wish to compete with a prospect of success this year, the better plan would be to purchase some healthy young plants. For exhibition purposes, the cuttings should be struck either early in the winter, or at the latest by the end of February. If the cuttings are taken as soon as the plants go out of flower they may be inserted either separately in small pots or about nine together in a 6-in. pot, and placed in a cold house, where hard frosts are excluded. By March they should be potted into small pots in a compost of half loam and leaf-mould, keeping them in a cold frame, merely protecting against vicissitudes of climate, avoiding all semblance of coddling, and throwing off the sashes in mild weather. Shift on as needed, adding about one-sixth of rotten manure to the compost; and during the summer months place the plants in a sunny situation, half plunging the pots, but never allowing the roots to go through. A centre stake and a few more placed round the edge of the pot will suffice for training purposes, as if stopping has been attended to in the earlier stages of growth there will be an abundance of shoots at the base wherewith the desired pyramidal shape may be worked out. Stop the shoots for the last time about the latter end of August.—J. C., *Byfleet*.

1770.—Climbers for Walls.—Ampelopsis Veitchi, which clings to the wall like Ivy, and which displays such beautiful and striking tints in autumn, should do well in the situation mentioned. We should, however, imagine that either the drainage must be very defective or the soil radically bad, or the Virginian Creeper would not fail. The best way would be to take out about 2 ft. of soil in depth by 3 ft. in width, and replace it with some well-sweetened mould, mixing with it some thoroughly well-decomposed manure. A little silver-sand, mortar rubbish, or anything of a similar nature, would serve to render the soil free and to preserve in a sweet condition. The great point in planting climbers is to give them a good start; once established they generally manage to take care of themselves.—J. C. B.

1750.—Leather Dust in the Garden.—Leather dust contains a high percentage of nitrogenous matter, which is, however, in a very inactive condition, and will therefore only give up this most valuable ingredient of all manures after a long process of decomposition. Being in a fine state of division, it is a very good manure, though not very quick in its results. "H. N." makes a mistake in burning it, as in burning all the nitrogen will be driven off, and the whole converted into a carbonaceous mass, containing a very small percentage of ammonia in an active state, and a small quantity of mineral ingredients. If I understand his question properly, he burns the leather dust along with wood, and if this is so, he positively does harm, inasmuch as the nitrogenous material of the leather will combine with the alkaline bases of the wood, forming cyanides, which are highly prejudicial to plant life. The residue or ash of burnt wood is a very valuable manure, and used in combination with the unburnt leather dust still further increases its value. If the leather dust can be boiled or steamed under pressure it would make it much more active as a manure.—Florist.

1791.—Sowing Begonias.—If sown now and the pots are plunged in a mild hotbed, or placed in a warm house where the day temperature ranges at 60°, the seed will soon germinate, and if the seedlings are pricked off into pans, to be from thence transplanted into small pots, shifting on when necessary, and keeping them in a moist heat, they will attain sufficiently

Greig's Tulip (Tulipa Greigi).

large proportions to flower in a cool greenhouse by the latter end of August. It it better to sow, if possible, by the middle of January; not only do the plants then attain larger proportions, but they come earlier into bloom.—C.

1775.—Gladioli for Exhibition.—Gladioli grown in 6-in. pots would not produce spikes suitable for exhibition. Plant them in good, rich, deep soil, and when about 1 ft. high, mulch them with good manure. As soon as the spikes appear in the foliage, give them a good soaking with liquid manure twice a week. Stake each spike, in order to secure them from damage by wind. As soon as the flowers begin to expand, protect them with shelters made of thin boards nailed to a stake, which will form half a square; tie the spike into this, and it will protect them from boisterous weather.—Weston-super-Mare.

1881.—Plants for Baskets.—Amongst the prettiest of basket plants raised from seed are the Thunbergias, orange, buff, and white, which should be sown at once in a gentle heat. These are creepers, and hang down over the sides of baskets with graceful effect. Phlox Drummondi, in several colours, are also very admirable basket plants; so also are the diverse shaded blues of the Lobelia speciosa. Climbing Tropæolums of the Lobbianum section are too coarse raised from seed, but plants from cuttings will do admirably. The Canary Creeper may do for the purpose. Portulaccas are also very beautiful creeping plants, and flower well if exposed to the sun; and Nemophilas, though much hardier, are also very effective. A few of the dwarfer ornamental Grasses, if sown at once in small pots, should give valuable and effective foliage additions; and some of the Mesembryanthemums would also be useful. In filling baskets it is too commonly the rule to stuff them with Fuchsias, Pelargoniums, Calceolarias, and all kinds of plants that have no affini y either in character or habit with the baskets. All this is very ridiculous, and cannot be too much discountenanced. The great charm of a hanging basket lies in the comparatively untrained free growth of its denizens; and this should specially run about over its sides and hang down in such graceful profusion as should hide the material of the basket from view. Generally there is an attempt to get too much out of a basket: rather it should be the object of the cultivator to get as much beauty as possible out of the least and simplest and at the same time most suitable materials.—A. D.

1886.—Hardy Annuals, &c.—One of the very best and longest blooming of all annuals is Mignonette; but this is not so enduring and lasting in pots as in the open ground, and if bunches of bloom were cut from it often, there would remain little else but bare stems. Calliopsis bicolor, Collinsia bicolor, Chrysanthemum Dunnetti, and C. frutescens are rather tall, but hardy, and offer admirable flowers for cutting. Dwarf Helichrysums, double Larkspurs, and double Clarkias also offer excellent cut flowers, as also do the double and semi-double Indian Pinks (Dianthus Heddiwigi fl.-pl.). White, carmine, and crimson Candytufts are also very good for cutting, and effective in pots. There are many dwarf-growing annuals that are better suited for pot culture, but which would give anything but useful flowers to cut from. Of these Gillia tricolor, Nemophila insignis, Feuzlia diantheflora, and others, are examples. The pots in which the annuals are grown should be at least 6 in. to 7 in. in diameter, and before growing should be filled nearly to the top of the rim with good free loam and well decomposed manure, and a slight mixture of fine sand over the surface. As the soil settles down, it will be found that there is ample room to give water, which, when the plants are full grown, will be largely needed. Some weak manure water would prove very efficacious, and help to sustain growth and bloom for a longer period.—D.

1860.—Woodlice in Melon Frames. Woodlice are troublesome pests in frames and Mushroom houses. I have tried many of the insecticides with but little success. The best remedy I know of is to place several toads in the house; they are ravenous feeders, and soon reduce woodlice, with all other small insects that may chance to come in their way. Toads may easily be obtained in the spring about twilight; they can be picked up by the road sides or in the woods. I caught eighteen in about an hour last spring. I keep several in each house, and am not much troubled with such insects as they feed on.—Weston-super-Mare.

—— I catch quantities of woodlice in the following manner:—I get some 3-in. pots, and place in them Potatoes sliced thinly; I then place a piece of hay, so as to cover the tops of the flower-pots, and lay the pots on their sides. I do this at night, and go round in the morning and examine them, when I put the woodlice into boiling water.—H. E.

—— "E. O." cannot do better than place some toads in his frames and houses. The natural food of toads are insects of all kinds, and in my Cucumber house and Melon house I kept three or four toads in each bin (one bin on each side of a span-roofed house), and my plants are free in every way from all parasites.—W. S. R.

1873.—Lilies in Windows.—Lilies should thrive very well in an east window if the soil in which they are grown is suitable. The best compost is found in one-half turfy loam and the other half a mixture of fresh soil, well-rotted manure, and silver sand. It should be understood that nearly all kinds of plants grown in pots are cultivated under very artificial conditions. Lilies are grand hardy border flowers, and as a rule thrive well in ordinary garden soil; but in pots, where the root-space is limited, not only must the soil be rich, but it must also be open and porous. After constant watering for a few months, stiff adhesive soil will close round

the bulbs and roots as if in a vice, and almost kill them by such excessive compression. Compost for these bulbs is therefore of first consequence, and before potting the greatest care should be exercised to procure some that meets the above requirements. The bulbs would have been better if kept in the soil in which they grew last winter, and should have been potted into fresh soil earlier than this, because in such case more roots would have been formed ere growth came than will be so now. Plant the bulbs about 1 in. below the surface of the soil, and when the stems are several inches in height add a little more soil to feed the stem roots. The quantity of water required must be regulated by the needs of the plants, and no decided rule can be laid down. After the stems have died down, the pots may be put in a cool, dry place for the winter, and in the spring the bulbs re-potted as before.—A.

1898.—**Camellias in the Open Air.**—As a rule Camellias, where planted out in the open ground, whether against walls or in the open ground, do well if the situation be not bleak and the soil suitable. In many places they do well in low situations where the soil is stiff, but which has been assisted by a good portion of leaf-soil and peat. In others, where the soil is naturally good, deep, and well-drained, the Camellia thrives splendidly as a common shrub. It is found by ordinary experience that the plants when first turned out want some shelter from cold winds and scorching rains until well established. We have found them thrive best where there is shade at all times during the middle of the day. In many places the plants would do remarkably well if planted out with confidence, but as a rule the Camellia is treated as a greenhouse plant, and after it has been half-starved in a pot then it is turned out into the open ground as an experiment, and, as might be expected, it too often fails. For outdoor culture young plants of Camellias of the most robust sorts should be specially grown on, and be exposed and hardened off as much as possible before planting out; and, further, the roots should not be allowed to become pot-bound and half-starved. The check thus given cannot be overcome for a long time. Some day, when gardeners realise fully how hardy the Camellia is they will give it in the open air the place it is so admirably fitted to fill.—A. D.

1848.—**Striking Myrtles, &c.**—I strike any number of cuttings of Myrtles, Honeysuckles, Fuchsias, Roses, and pipings of Pinks, &c., in the following very easy way. Get a 6-in. pot, stop the drainage hole with a cork, and fill the pot with water. Place it inside a 9-in. pot, with the tops of the two as nearly even as possible, and fill up the space between the pots with soil suitable for cutting. Plant the cuttings round close against the pot of water, and keep the whole closely covered with a glass. The cuttings require no attention, and in from two to four weeks they have nice roots, and are ready for transplanting. To see if they are rooted give them a slight pull, and if they keep firm in the soil they are rooted. I keep the pot in a north border, slightly shaded by Laurels. —MARK.

1900. — **Cats in Gardens.** — Valerian plants attract cats; so does Nemophila insignis. It is quite astonishing what trouble I have to keep my cat from nibbling and rolling over the young plants of Nemophila. I once entered my garden armed with pieces of Gorse; he saw me put them on my Nemophila, and directly my back was turned sent off the prickly impediment and rolled away with redoubled energy. I sowed some seeds in a deal frame covered with a glass slide; the glass got broken, and I found his huge body wedged in the small aperture. Finally I came off victorious with pea-wires; although he did his best to knock them off with his nose. Cats have the greatest dislike to Rue. —MARK.

—— There is no doubt, I think, that cats have a partiality for certain plants; but I cannot speak with any certainty as to the Valerian; and neither do I know of any plant that would be so objectionable to cats as to keep them from the garden. They are more troublesome at this season than any other, because, like all animals, they like to bask on fresh bright surfaces, like freshly-stirred beds and borders, in spring.—E. H.

1880.—**Camellias from Seed.**—Select a clean pot; place 2 in. of drainage, such as broken pots, in the bottom, arranged with the largest pieces below. On this lay 2 in. of rough peat or turf, and then fill up to within an inch of the top of the pot with sandy peat. Water, and leave to drain for an hour. Sow the seeds, and cover with a ¼ in. of very sandy peat; place a bell-glass over the pot, and pot and plunge in a bottom-heat of 75° or 80°. Keep the soil just moist till the young plants appear; then both air and water in sufficient measure will be necessary.—H.

1883.—**Rose Leaves Spotted.**—Perhaps the bright sunshine we have had lately has scorched the Rose leaves; or the plant may have suffered from want of water or nourishment generally. Under such conditions the effect of bright days and cold frosty nights would be greater.—E H.

1896.—**Narcissi Failing.**—It is difficult to find a cause for the failure. One would think at first sight there was something deleterious in the soil or water, but the Hyacinths doing well in the same precludes the adoption of that view. All bulbs have their flower-spike secreted in the bulb; the result of the previous year's growth. In this case, perhaps, the bulbs may have been weak and faulty.—E. H.

1879.—**Propagating Aralia Sieboldi.**—The best way is to sow seeds; but cuttings of ripened wood will strike in a little bottom heat, kept close. Cuttings of the thick fleshy roots will also grow and make good plants.—E. H.

1898.—**Camellias in Open Air.**—Wait until the sap begins to flow, then carefully prune out all dead wood. There is nothing else that can be done for it. If not too far gone, nature may restore it.—E.

1884.—**Propagating Bouvardias.** — Cuttings of the soft young shoots strike readily in sandy soil, plunged in a bottom heat of 80°. Prune the old plants back now. Keep them rather dry till they break, and plant them out in rich soil in a warm sunny position in the open air in June. Lift again and repot in September.—E. H.

1877.—**Gardenias.**—A night temperature of 60° to 65°, with a corresponding advance in the daylight, plenty of moisture, both in the atmosphere and at the root. Pot in rough, fibry, turfy soil, chiefly peat, with plenty of clean sand to make it porous; and be persevering as regards cleanliness. Gardenias are very subject to mealy bug; paraffin oil, a wineglassful to three gallons of water, incessantly stirred up, is a good remedy.—E. H.

1890.—**Clematis from Seed.**—Gather and sow the seeds as soon as ripe in pans of peaty soil; keep the pans in a cold pit till the spring, then give a gentle warmth, such as is commonly found in a hotbed at this season.—E. H.

1891.—**Cobea scandens from Seed.**—The Cobea scandens ought not to die in a greenhouse in winter. It blooms freely enough in the open air if sown early enough and grown on rapidly. A good plan to get plants to bloom well in a small greenhouse would be to strike a few cuttings in August. Keep them in small pots in the greenhouse through the winter, and pot on and grow rapidly in spring. One or two plants will cover the whole roof of the greenhouse and yield plenty of blossoms.—H.

1894.—**Cyclamens and Cacti Blooming.**—Place the Cyclamens in a cold frame to complete their growth, giving as much water as necessary for that purpose, gradually withholding it as the foliage ripens. The Cacti must have every encouragement given them until growth is finished; then they must have less, to induce firmness or ripeness of the new growth, as without this there will be no flowers.—E. H.

Pine-apple Culture.—*A. B.*—Now is a good time to commence Pine-apple culture. Procure through some reliable nurseryman some good strong suckers, and be careful that they are free from mealy bug. Smooth Cayenne is the most useful kind to grow.

1895.—**Green Flower Pots.**—If scrubbing with sand and water does not remove the green stains from flower-pots, it will be cheaper and better to buy new, and obtain them from a maker whose pots are not so absorbent of indelible stains.—E. H.

1878.—**How to Grow Aconites.**—Winter Aconites will grow anywhere, but they succeed best on banks that are never dug over or disturbed. The tall growing Aconite or Monkshood will thrive well in any ordinary garden soil; and they also do best if left for a number of years without removal.—E. H.

1787.—**Hyacinths not Growing.**—The bulbs are in all probability quite dead. They should be in bloom now unless the soil has been maintained in a dry state, in which state they might have refused to start. If the bulbs are still sound, plant them in the open ground.—C.

1844.—**Making a Kiln.**—I have seen lime burnt in turf kilns very successfully, but with coal in layers with the limestone. The kiln was about 2 ft. high, and 2 yds. to 3 yds. in diameter.—J. M. R.

1845.—**Guano for Plants.**—1 oz. of guano to 1 gal. of water would be quite sufficient for most plants. The water should not be used directly, but be left to allow the guano to get well dissolved in the water.—CALAMUS.

1780.—**Culture of Polemonium confertum.**—*H. C.*—All kinds of Polemoniaceæ succeed best in gravelly or chalky soil. A shady bank is a good situation for them. All are increased by dividing the roots.—AMATEUR R. K.

1848.—**Propagating Oleanders.**—Take cuttings of Oleander and put them in a common pickle bottle kept filled with water in a warm kitchen. They will soon throw out numerous rootlets, and may then be potted. I have succeeded in raising half-a-dozen plants in this way, all of which are thriving.—F. C. M.

1852.—**Carnations and Hares and Rabbits.**—I have found the following plan most successful where rabbits and hares abound:—Take sticks about the size of one's little finger, and about 1 ft. in length, and tar 6 in. of the tops, and insert the remaining part in the ground, placing about four around each Carnation.—H. E.

1901.—**Early Flowering of Lilium auratum.**—We have in our garden a Lily which flowered on the 22nd of March. We consider it to be Lilium auratum. Is it not very early?—M. F., *Lostwithiel, Cornwall.* [It was very early for L. auratum; but we question if it was that kind.]

1902.—**Soil for Araucarias.**—I have a very nice Araucaria on a lawn, but it now seems to require some assistance. What kind of artificial manure should I apply, and what soil?—H. O. [Give it a top-dressing with good turfy loam, and any decayed vegetable matter. If you must have artificial manure, crushed bones would be as good as anything.]

1903.—**Cutting Down Hollies.**—Having a hedge of the common Holly in front of my house, about 13 ft. high, which darkens the rooms, would it be safe to reduce it to about 6 ft. high?—JAMES KIDWELL. [Yes, it would be perfectly safe. Cut with a sharp bill-hook or knife, not a saw.]

1904.—**Roses on Galvanised Wire.**—A few years ago I made several arches in my garden, and covered them with galvanised wire netting. I have since planted several different hardy sorts of Roses to climb over them; but in each instance the branches turn black by contact with the wire. Is there any cure for this?—J. J. M. [Paint the wire.]

1905.—**Hybridising Daffodils.**—I observe in a recent issue of GARDENING that Daffodils may be greatly improved by hybridisation, and that the process is very simple. Would you kindly inform me how to carry it out with a prospect of success?—AN AMATEUR. [For hybridising purposes it is best to grow the plants in pots; and when in bloom a cool greenhouse, frame, or sunny window is a good place for them. The common yellow Daffodil and Polyanthus Narcissus "States General" crossed give fine sorts, but as the last named flowers later than the Daffodil, it must be forced into bloom. Pollen of early blooming sorts may be shaken out, and kept for several weeks in dry tinfoil or silver paper. Remove the pollen with a small brush from the anthers of one flower to the stigma of another, as may be desired. The anthers of the seed parent may be extracted before the stigma is fit for fertilisation, by carefully slitting the tube. You should consult Burbidge's "Narcissus," a book on Narcissus which gives information on crossing them, or "Cultivated Plants," another work by the same author, in which see under "Narcissus." These works are expensive, but may be seen in all good public libraries.]

1906.—**Horticultural Boilers and Furnaces.**—Many makers of boilers insist strongly on the advisability of the fire being surrounded by parts of the boiler containing water (and the use of water bars), which are, of course, iron, and consequently always comparatively cold. On the other hand, others say that all parts of the furnace in contact with the fire should be of non-conducting materials, as firebrick; otherwise, they say, the effect is bad and imperfect combustion, and, instead of producing heat, the fuel is dissipated by dry distillation and goes away in smoke unconsumed. I find that in domestic fireplaces an iron-backed range does burn dull, with a deal of smoke and little heat; whilst a brick fireplace gives a bright fire, perfect combustion, and a good heat with little smoke. Are the first named boilers adapted only for the consumption of coke, and not coal —YORKSHIRE. [Coal may be burnt, but it requires more attention and makes more smoke than coke. Small coa and coke mixed make good fuel, if kept well wetted.]

1907.—**Air Roots on Vines.**—What causes aerial roots to come on Vines, and how may they be prevented? —ARGIA. [The tops of the Vines being in a higher temperature than the roots, together with the close, moist atmosphere of the house, is the cause assigned for aerial roots on Vines. They do no particular injury, and can be prevented by having a well-drained warm border, and keeping a dry atmosphere in the Vinery. We should not advise you to attempt to prevent the roots forming if the crop is good.]

1908.—**Cocoa-nut Fibre for Cuttings.**—On page 812 of Vol. I. it is stated that Cocoa-nut fibre "answers well for draining pots, and cuttings strike readily in it. Is it to be understood that cuttings will strike in the fibre without admixture of mould or other compost?—J. S. C. [Yes.]

1909.—**Tuberous Begonias.**—Some time ago I sowed a few Begonia seeds, only just covering the seeds with soil and sand. The young plants are now nearly 2 in. high; should they be potted off singly into small pots? If so, how deep should the young bulb be planted beneath the surface of the soil? I have heard it said that the bulbs should not be entirely buried.—A LEARNER. [Pot the plants singly in 3 in. or 4 in. pots, using light loam and leaf-soil and silver sand. The young bulbs should be just covered in the soil, but not buried deeply.]

1910.—**Camellias Out-of-doors.**—A Camellia planted out-of-doors early last autumn has lived through the severe winter without any protection. It looks very forlorn, but has not lost its buds. Can I do anything to revive it?—J. K. A. [Pick off its buds, and it may break into growth shortly.]

1911.—**Bulbs the Second Year.**—What is the reason of bulbs never producing equally handsome flowers the second season as the first? I find my Hyacinths annually deteriorate if I do not buy fresh bulbs every year. Can any one tell me how the florists and seedsmen from whom one purchases bulbs manage? Is there any way of treating them when they have finished flowering that will cause them to bear fine flowers the following year? E. B. KENNEDY. [The florists and nurserymen buy these bulbs fresh every year from Holland, where they are grown expressly for sale. The Dutch growers do not let their bulbs flower, but direct all the energies of the plant to the formation of well-ripened bulbs; hence the fine results from imported bulbs. If you plant imported bulbs in rich deep soil, and leave them in the ground after flowering, simply mulching them with rotten manure in winter, you may have fair flowers for several years, but not equal to those produced the first year.]

1912.—**Red Cabbage Seed.**—Will Red Cabbage seed sown now produce marketable heads?—E. L. [Yes; but they will not be so large as those from autumn-sown plants.]

Substitute for Pea Sticks.—*K. K.*—The method described answer 1805 is so simple that any one may understand it by reading and thinking.

Heating Apparatus for Small Greenhouse.—*Amateur.*—The back numbers of GARDENING contain a vast amount of information on this subject.

M. K.—Apply to Mr. Charles Turner, Royal Nurseries, Slough.

Cucumbers in Pit.—*J. M. R.*—If the plants have not made much growth since they were planted out, you could easily lift them, and, having put fresh soil, replant them. The soil must be warm before the plants are replanted. The price of "London Market Gardens" is 3s. 6d., post free 3s. 9d.

Names of Plants.—*J. M., Sheffield.*—Chorophytum orchidastrum; it will grow in a greenhouse or sunny window, and in any good potting soil.——*Harroviensis.*—Daphne Mezereum. You might try some cuttings placed firmly in sandy soil in a shady situation, under a hand-light.——*Ilkeston.*—Thujopsis borealis, Thujopsis dolobrata, probably; but from such scraps we cannot be certain.——*P. Q. R.*—1, Tussilago farfara grande (variegated variety of the Coltsfoot); 2, German Ivy (Senecio mikanoides).

QUERIES.

1913.—**Pruning Coronillas and Genistas.**—When is the proper time for cutting Coronillas and Genistas? Two of my largest Coronilla trees have died through wrong treatment.—J. K. A.

1914.—**Improving Soil for Potatoes.**—I have a piece of ground of a sandy nature which I have repeatedly manured for Potatoes; but, in spite of this, sand it still remains, and the Potatoes are very small. I have spread nightsoil over the surface for digging in. Will anyone kindly give me information as to improving the condition of the soil?—Amateur R. K.

1915.—**Greenhouse in an Engine Room.**—I am about making alterations in my boiler and engine room, and think of making the roof and ends of glass. Would anyone suggest plants suitable to grow in such a place? It would receive a large amount of sun during the greater part of the day. Size, 30 ft. by 30. ft.

1916.—**India Rubber Plant.**—What is the matter with my India Rubber plant? It grows and the top leaves look healthy, but the lower turn yellow and drop off three or four at a time. It stands in a south window.—A. B. C.

1917.—**Plants for Greenhouse.**—Will some one kindly tell me the best plants for a greenhouse heated in winter by a paraffin stove? Geraniums die, and Azaleas, Myrtles, &c., although they live, never blossom. What is the cause?.—A. B. C.

1918.—**Window Plants.**—What plants are likely to thrive best (in a south window) where gas is burned in the room two or three evenings a week?—A. B. C.

1919.—**Soil for the Royal Fern.**—What is the best soil for Osmunda regalis, and the proper treatment of same?—W. H.

1920.—**Manure for Cucumbers.**—Will any one with experience inform me through Gardening Illustrated the best kind of manure for mulching Cucumber beds after the plants are established? The house is heated by a flue.—J. H. W.

1921.—**Keeping old Primulas**—Which is the best way to treat Primulas when they have done flowering? I know it is best to raise fresh plants from seed; but I wish also to keep some of the old ones.—W. B. W.

1922.—**Propagating Aralia Veitchi.**—I have an Aralia Veitchi, which I have cut down, it having grown too high for my house. The portion removed I divided into cuttings, which I attempted to strike in heat; they have all died. How ought they to be struck? or should they be grafted, and, if so, on what stock?—C. A. S.

1923.—**Peas with Beetles Inside.**—I have some Peas which to all outward appearance seem solid and firm; but when I come to examine them and split them open there is a small brown beetle inside them. I found this out quite by accident. I should like to know whether any of the readers of Gardening Illustrated have experienced anything like it.—Gardener.

1924.—**Tortoise in Vineries.**—I have some tortoises in a Vinery and should be glad to know what to feed them with, and where they come from, and whether they will do any harm to the Vines. The heat of the house is from 70° to 99°.—F. Johns.

1925.—**Begonia Seed not Germinating.**—Can any reader inform me the length of time the seed of the above will usually take to germinate. I bought (of a very respectable firm) a packet of seed, and sowed it seven weeks ago, following the printed instructions minutely, keeping them in a house at a temperature of 60°; but not any have appeared above the soil. I wish to know if there is still any chance of them doing so; or should I buy again?—A. T. E.

1926.—**Green Carpeting Plants.**—I wish to cover three flower borders with a permanent green carpet requiring no cutting, not growing, therefore, above two or three inches high. One border is in partial shade, one moderately sunny, and the third in full sunshine. Can I do that quickly with seed? and would mossy Saxifrages or Sedums, or Spergula pilifera or Pyrethrum Tchihatchewi, be suitable, or can others be mentioned better for the purpose, with a view to the three different aspects? supposing no one good one will suit all, which I should prefer for the simple oneness of colour effect?—J. S.

1927.—**Gardening in London.**—How can I best keep a piece of ground a few yards square, in London, gay with summer flowers?—J.

1928.—**Plants for Floating in Water.**—What seed can I sow successfully on a cork island floating in my aquarium? It is always wet and cold, and stands in the shade in the house. I have tried Lycopodium of various sorts and failed. I would like English names given as well as botanical ones.—E. G.

1929.—**Lilium auratum Out-of-doors.**—Will some reader give me the benefit of his experience in growing Lilium auratum and other high-class Lilies out-of-doors, in such a climate as Notts, where during the last winter all our Aucuba japonicas have been cut down to the ground by frost? I have twice tried, and twice failed; but shall be glad to find that this was from bad management, and not from the impossibility of the thing. I found that in the first place the blooming was not till September or October, which is far too late; and, secondly, that the following winter killed the bulbs.—J. J. S.

1930.—**Begonias and Cockscombs.**—Will some one give me the best method for growing Begonias and Cockscombs?—A Novice.

1931.—**Varieties of Chrysanthemums.**—Would some one kindly give a list of the twelve best incurved Chrysanthemums? Also a few of the smallest flowering ones suitable for the button-hole. Of course, I should like a variety of colours in the small kinds as well as large.—Alpha.

1932.—**How to Make a Fern-case.**—I want to make a Fern-case. Will any one tell me the best mode of making one, neat in appearance and simple in construction, and whether the Ferns do as well in one with a flat top as one raised to a dome? The size I want to make it will be about 2 ft. 4 in. by 18 in. wide. What height should such a case be, and what Ferns will thrive the best in it? I want to make one that will not require artificial heat. Full particulars as to construction and other details will greatly oblige.—S. W.

1933.—**Caterpillars on Cabbages.**—What will destroy caterpillars on Cabbages? What is the name of the common black slug? What is the best way to destroy it?—Westernville.

1934.—**Ferns for Damp Cave.**—Will some one give me a list of hardy Ferns suited for a small cave where there is a constant drip of water? Hymenophyllum is well established there already.—H. H. Townsend.

1935.—**Tree Carnations and Picotees.**—I have twelve fine assorted plants in pots in a cool greenhouse, which has the sun upon it from early morning until midday. I shall feel grateful for some good sound advice as to their management at this time (some are now in bud), and later on, and during the winter (when I have a paraffin stove); also as to watering, repotting, soil to be used, and how best to procure it.—W. H. H.

POULTRY.

Perches for Fowls.—A very common mistake is that of having the perches in the roosting house at too great a height from the ground. For large breeds, such as the Cochin or Brahma, 12 in. is quite high enough; and for small breeds, such as the Hamburg, 18 in. to 24 in. Many diseases, such as bumble-foot, corns, or leg weakness, are often caused by alighting from a high roost. It may be said that a hen-ladder, the construction of which is familiar to all poultry keepers, will obviate this evil; but it will generally be found that although the birds make use of it to ascend to roost in the evening they will decline to do so when descending in the morning, and fly direct on to the floor, often with terrific force, thereby straining themselves, and sometimes forcing pieces of gravel or cinder into the balls of the feet, which at once causes a sore and very likely lames the bird for life. Flat pieces of timber, varying in width from 2½ in. to 4 in., according to the size of the birds, are best for perches. Let them be of sufficient thickness to prevent their being "planky," when the birds move on them. They should be placed firmly, either in niches in the wall or on posts let into the ground; but this will depend on the shape and material of the house. Let them be as far as possible from the door or outlet, and near the window, as fowls like light. They should be white-washed at the same time as the walls of the house; and should the birds foul them it should be carefully scraped away. Many large breeds do not care for roosting, and some fanciers bed them on straw, which must be shaken up every morning; but a better plan is to cover the floor with lime and earth to the depth of 2 in. and change twice a week.—Andalusian.

Eggs for Sitting.—Eggs intended for sitting should be gathered up from the nests as soon as possible after being laid, in order that they may not become soiled, as dirty or greasy-looking eggs should never be put under a hen. Shelves, pierced with holes large enough to receive the egg, but not so as to let it slip through, should be fitted up in a room of moderate temperature, and the eggs placed in them large end downwards. In this manner they may be kept for ten days or a fortnight without destroying the vitality. Eggs only of a fair size should be selected, discarding the very large or unusually small ones, and it is advisable not to use those laid by pullets for the first fortnight after they commence to lay. Misshapen ones, or those having the least crack or chip in the shell are useless. It is pretended by some fanciers that they can by the shape of the eggs make a good guess as to whether the produce will be cocks or hens, but little or no faith is to be placed in such theories. The number of eggs to be placed under each hen must be regulated by the state of the weather and the size of the hen, but thirteen may be taken as the average, which number a medium-sized Brahma or Cochin will cover comfortably. It is a good plan to sit two hens on the same day, so that by using an egg-tester about the eighth day, the unfertile ones can be thrown away and the whole of the fertile ones, if not too many, placed under one hen, while the other hen may be given a fresh sitting. If eggs be received from a distance, by rail or otherwise, they should be unpacked carefully and placed under a hen immediately on arrival.—Andalusian.

Bones for Fowls.—We prefer giving our fowls the bones, after crushing them as they come from the table, or even in a raw state. There is no advantage to be gained in baking them; in fact, same of the useful properties are lost; as, for instance, the fatty matter contained in raw or cooked bones is wasted when they are baked. If old mortar is within reach of the fowls they will take care to eat as much as is required to enable them to form the egg-shells. If the bottom of the roosting place is dry and covered with straw or leaves, or any other dry soft rubbish, it will not be injurious to the birds if they roost on the floor at night. Perhaps the roosts are placed too high for the birds to fly up. We never put our own roosts for heavy-bodied birds, such as Brahmas and Cochins, more than 2 ft. above the ground.

Eggs Without Shells.—Give the hens some broken oyster-shells, and let them have as much exercise as possible. Discontinue all stimulating food, and feed them very moderately with barley. We fear you have been over-feeding the birds.

Fowls for Clayey Soil.—If the soil is drained it will not much matter what variety is kept, for so much depends upon the care and management of the birds. Either Brahmas or Cochins would do well, or, if there is plenty of room, Game.

Roup in Fowls.—Roup or croup generally in the first instance proceeds from a cold. A liquid discharge soon follows from the nostrils, the flesh round the eyes becomes swollen, and the eyes frothy. In a few days the discharge becomes most offensive; the disease is then highly contagious. The sick bird should be removed, and put in a warm, dry place; the eyes and nostrils frequently washed with Condy's fluid diluted with warm water, and a teaspoonful of castor-oil may be given three or four times a week.

Pullets not Laying.—To keep fowls in a small yard with little or no exercise, feeding them three or four times a day, and then expect them to lay, is simply going dead against nature. It must be remembered the natural habit of fowls is to be continually on the move, hunting for their food in the fresh air; and they are seldom quiet during the day. Reduce the feeding to two meals daily, let them have as much exercise as possible, and there will then be no cause to complain of pullets not laying. Our own birds have a good feed in the morning, consisting of Barley meal, middlings, and Chamberlain's food, mixed with scalding water; they then have the run of a large lawn, and are fed in the afternoon (about five) with Corn; and we have eggs in abundance since Christmas.

Mopish Fowls.—There must have been something radically wrong, either in the feeding or sanitary arrangements, for the whole of "Tonic's" fowls to have gone amiss at the same time. Then their marvellous cure in ten days looks as though he had an interest in puffing the wonderful mixture which he mentions. My knowledge and experience with poultry, extending over something like five and twenty years, tells me that little faith is to be placed in these mixtures. Occasionally they may prove beneficial; but in nine cases out of ten they are useless. What fowls want, and what they must have if they are to be kept in a healthy condition, is plenty of fresh air, cleanliness, and regularity in feeding with good sound wholesome food; then there will be no need to use these nostrums.—W. J. N.

Fowls not Laying.—I have three Brahma hens which are very poor layers. During the last week or two I have had two eggs from one of them no bigger than those of a pigeon. They are fed on maize and barley occasionally. They have been used to running about the garden, but are now shut up.—H. H.

Fowls with Swelled Beaks.—I have got some half-game and Dorking hens; two of them have swelled beaks, and look very yellow about the beak, and rather frothy at times, and their legs are very yellow. What is the matter with them? They are very fat, and eat well, and do not lay amiss.—Good Health.

HOME PETS.

Canary Breeding.—I beg to submit my system of breeding Canaries, which I have followed most successfully for nearly twenty years. I have a large wire cage, 1 ft. wide, 1½ ft. long, and 18 in. high, which stands either in a window or on a table in a landing, a place which might be thought too draughty and cold, but my birds are perfectly healthy and hardy, and even during this cold winter have never been in a room with a fire. The cage generally contains seven or eight birds, but early in March I take out all except the pair I intend to breed from. I feed these as usual with Canary seed, but I also supply them liberally with Maw seed; and I take care that they are not long without Groundsel or Chickweed. I hang a nest-box in the corner of the cages, and near it a net with cow's hair,

which is the only material I allow for building, as I have found moss, wool, &c., cripple the young birds. The hen soon builds her nest, but if she is clumsy or lazy about it I do it for her, packing the hair, which must be smooth and clean, in thickly and evenly, making a hollow large enough for the birds in the centre. If the hen seems weak I give her some chopped egg for a day or two, or even now and then a little bit of bread sopped in wine, or any other dainty. But generally they do very well on plain food, with vegetables, which must not be forgotten. When the eggs are laid I move the cage as little as possible, and am careful, when obliged to take out the board for cleaning, not to shake the nest. When the young birds are hatched I put in a supply of egg and Maw seed two or three times in the day. In hot weather the egg is apt to get sour if too long in the cage, and this must be guarded against. When the young birds are three weeks old I put them into a cage by themselves, and if they do not eat properly I put the two cages close together, so that the old birds can feed them through the bars. I do not give the old birds a bath when they are laying or sitting, unless the weather is very hot and dry; nor do I let the young birds wash until they are fully fledged. I never have any trouble with my birds; and until last season, which was the worst I have ever known, I have been most successful, rearing five or six families from one pair every year. The great secret is—plenty of fresh air, cleanliness, and variety of food.—J. A. M.

Stuffing Birds.—A simple manner of doing this is as follows:—The entrails should be taken out, for which purpose the stomach should be carefully cut open, taking care not to injure the feathers; afterwards the brain should be taken out through the mouth. Take care not to tear the membranes of the bill in doing so. After having done this, the inside of the skull and also the body should be filled with a mixture of pepper, salt, and alum. Put the bird in a cool place for a short time, then dry before the fire. The object of putting in this mixture is to absorb all the moisture, &c., from the body. After this has been accomplished, take out the pepper, &c., and fill the bird with some soft substance, and arrange the bird as you wish it to remain. The wings and tail can be kept in position with fine wire, which is sold for the purpose. This wire and the eyes can be bought and sent by post by any London naturalist, such as Gardiner, Holborn. The 1s. book on bird stuffing can also be procured at the same place.—A. D'A.

Birds for Aviary.—*Evan Dhu.*—The aviary in question is rather small for a collection of British and foreign birds; however, I will endeavour to give the names of some that would be most likely to agree with one another, and also look well together. The first on the list must of course be the ever popular canary, of which one pair would be sufficient; next, a pair of budgerigars, one pair of love-birds, three or four pair of the tiny ornamental finches. A goldfinch, linnet, and siskin would be about the best to choose from English birds; it would not be worth while to have the three latter birds in pairs, as they are not likely to breed in such a small aviary.—A. D'A.

Bird Lice.—Do canaries suffer from these insects Yes, and "Tilly Slowboy" is quite right in thinking the insect powder is good. As these pests tend not only to distress the bird, but also to seriously impair its health, a tonic must be at the same time administered; and none is better for this purpose than "Finchine."—A. D'A.

Food for Bullfinches.—The best food for all cage birds, is to give them a varied supply of seed. I always let mine have the following mixture—Canary, Rape, Millet, Hemp, and Flax. When breeding, it is advisable to administer a little Maw seed, and also put a few drops of Chard's Finchine in their daily supply of water. This tends a great deal to brace them up, and keep illness or indisposition at a distance.—A. D'A.

Sitting Doves.—I have a pair of doves, but as they have laid four eggs, I fear that they are both hens. How can I distinguish them, and how long should they sit on their eggs?—AUGIE.

AQUARIA.

Crayfish in Aquaria.—These are very interesting objects to keep. They should be kept in an aquaria by themselves, with plenty of stones and shingle for them to burrow in. A little rockwork should be arranged in the middle to come just above the top of the water, so that they may get air if they require it. Nothing else should be kept with them, beetles or fish are certain to be killed by them; neither should any valuable water weeds be placed with them. A few sprays of Anacharis (the Canadian water weed) may float about in their habitation. They should be fed occasionally with small bloodworms. Four may be kept in a 12-in. glass, and will be objects of interest for a long while. I once kept six of them for nearly eighteen months. A friend of mine who kept some induced them to breed, and numbers of little fish half the size of shrimps were the result. I was never so lucky.—W. B.

Plants for an Aquarium.—I do not think any one has answered the question of "S." (Feb. 21, 1880) as to the "Lily with Trefoil leaves, and a bloom like the Horse Chestnut," which blossoms in his aquarium every spring. It is easily recognisable as the Buckbean (Menyanthes trifoliata), one of the most beautiful of English aquatic plants. It grows in several localites round London, but if in ponds or ditches is rather shy of flowering. It flowers in profusion in swampy meadows (dry at times) near one of the sources of the Thames—the Naunton Seven Springs, Gloucestershire.—C. V. A.

—— In reply to "S.," as to the name of a small Lily got in a pool in Galway, is it not Menyanthes trifoliata, the Buck or Bog Bean, commonly called Marsh Clover? It is described and figured by Miss Pratt in her "Flowering Plants of Great Britain."—MARY WAKOLINE, *Stoke Newington.*

Aquatics in Tubs.—Will "J. S." kindly give a little more information respecting water plants—what kind of soil, &c, the plants are to be put in, what depth of soil there is to be in the paraffin tubs, and where they can be procured?—W. J. H.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Owing to the recent bright weather, supplies, especially of the choicest fruits and vegetables, are now improving, though the demand for them is but limited. The commoner kinds of outdoor vegetables are cheaper; of forced and other flowers there are now good supplies, and prices are on the decrease.

Cut Flowers.—*Per dozen bunches.*—Anemone, 4s to 6s; Azalea, 6s to 12s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 4s to 9s; Heliotrope, 6s; Jonquils, 6s to 9s; Lily of the Valley (forced), 9s to 18s; Lilac (forced), 4s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus (paper-white), 6s to 9s; Narcissus (Pheasant's-eye), 1s 6d to 3s; Pelargoniums (zonal), 6s to 9s.; Pelargoniums (large flower), 12s to 18s; Pelargoniums (double), 6s to 12s; Pelargoniums (Rose-scented leaf), 6s; Primulas (single), 6s; Spiræas, 6s to 12s; Snowdrops, 2s to 3s; Tropæolums, 1s 6d to 3s; Tulips; 9s to 18s: Violets (blue), 1s to 2s; Violets (Neapolitan), 2s to 4s; Violets (French), 1s 6d to 4s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 4s to 9s; Camellias, 1s to 6s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenia, 4s to 8s; Roses (forced), 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias. 1s 8d to 3s; Euphorbia, 2s to 4s; Fuchsias, 4s to 6s; Hyacinths, 3s to 6s; Primulas (double), 9d to 1s; Stephanotis, 12s to 18s.

Plants in Pots.—*Per doz.*—Arbor-vitæ (golden), 9s to 18s; Arbor-vitæ (common), 6s to 12s; Azaleas (ordinary), 24s to 42s; Azaleas (hardy), 18s to 24s; Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Aralia Sieboldi, 12s to 30s; Ardisia crenulata, 18s to 30s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Berberis, 4s to 9s; Bouvardias, 12s to 18s; Box, 4s to 9s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Clematis, 9s to 18s; Crocus, 1s to 2s; Crotons (in variety), 12s to 42s; Cyclamen (ordinary), 9s to 24s; Daphne indica, 4s to 6s; Deutzia gracilis, 9s to 18s; Dielytra, 12s to 18s; Dracæna (green-leaved kinds), 12s to 30s; Dracæna (variegated), 18s to 60s; Ericas (hyemalis section), 6s to 18s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 30s to 36s; Hyacinths, 4s to 9s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Narcissus, 9s to 12s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 18s to 24s; Pelargoniums (scarlet), 6s to 9s; Pelargoniums (double), 6s to 12s; Primulas (single), 4s to 6s; Primulas (double), 9s to 18s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 9s to 18s; Scilla sibirica, 9s to 12s; Selaginella denticulata, 3s to 4s; Solanums, 6s to 9s; Tulips, 6s to 9s; Virginian Creepers, 6s to 9s. *Per pair.*—Azaleas (large), 20s; Maiden-hair Ferns (large), 5s to 7s; Aucubas (berried), 4s to 6s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 130s; Grapes (English hothouse), per lb, 10s to 15s; Grapes (imported Almeria), per barrel, 40s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pears (fine dessert kinds), per dozen, 9s to 12s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 1s 6d to 2s 6d.

Vegetables.—*Per* 100.—Asparagus, 8s to 12s; French Beans, 2s to 2s 6d. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 9s. to 12s; Parsley, 18s; Turnips (outdoor), 3s to 4s; Radishes, 1s 6d to 3s; Herbs, 2d to 6d. *Per dozen punnets.*—Cress, Mustard, or small salad, 2s; Seakale, 36s. to 48s. *Per dozen.*—Cucumbers, 12s to 18s; Endive, 2s to 3s; Lettuce, 1s to 2s.—*Per bundle.*—Celery, 1s to 4s; Horseradish, 3s to 6s; Salsafy, 6d to 9d.—*Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 1s 6d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 8s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 4s to 8s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

American Prairie Roses.—Do these flourish well in your climate? I found that English cultivators knew little or nothing about them, and I saw few, if any, plants of them. Certainly they are worthy of trial, for we have nothing here hardy enough for our climate that will compare with them in beauty. The Ayrshires are not hardy, and if they were they are so inferior they would not be cultivated; and the Boursault is only an apology for a good Rose, unless I except the dark variety. Without the Prairies we should be entirely deficient in hardy climbing Roses. They come into bloom just as other Roses are going out, and continue for a long time to display their fine double flowers, which appear in clusters of from ten to twenty blooms. They are vigorous rampant growers, never injured by the most severe winters, and bloom in the utmost profusion. We have now ten or fifteen varieties; and some account of their origin, which might be interesting, I may give you on some leisure occasion. The most distinct are Queen of the Prairies, Baltimore Belle, Mrs. Hovey, and Gem of the Prairies.—A. H., *Boston.*

Hardiness of Indian Azaleas.—There can be little doubt, I think, that a plant is hardy which has withstood our last few winters entirely uninjured, in fully exposed situations. Such is the case with the old white Indian Azalea, of which we have several planted out in the pleasure grounds. I lately came upon a fine bush of it in our woodland garden looking quite at home amongst Rhododendrons. It has made vigorous growths, and last summer most of our bushes of this variety flowered freely. They are certainly hardier than the common Laurel and Laurustinus, both of which are much browned at the ends of their shoots. Anyone fond of experiments regarding acclimatising plants may safely try the Indian Azalea.—J. G.

Neapolitan Violets to Bloom in Winter.—Divide the old plants after blooming in spring, and plant the runners on a cool border in rich light soil. Plant in lines a foot apart, and 10 in. from plant to plant in the row. Keep the surface stirred, and give copious waterings in dry weather. In September, take the plants up with good balls, and plant them in a frame near the glass in a sunny and sheltered situation. Give plenty of air when the weather is severe, and keep off the lights altogether in mild autumn weather.—O.

ZINNIAS.

THE Zinnia comes under the denomination of a half-hardy annual. The seed is sown in a gentle bottom heat in early spring, and the plants are hardened off and put out into the open ground to flower. Many spoil their plants by keeping them in the seed pans and boxes till they are planted out, and in consequence the plants become drawn and grow tall, instead of fine, free-branching examples. When they are grown thus thickly together the roots cannot well form good balls with soil adhering to them, and when transplanted the plants are some time before they make a start, and when they do they seldom branch out. Those who care for Zinnias prick off their plants from the seed-pans into other boxes, or into a bed in a cold frame, where they are put sufficiently far apart to form good balls of roots. It is a good plan to pot a few of the earliest of the plants, and grow them on to come into flower as soon as possible, so as to inaugurate a succession. The soil for the Zinnia should be of a light rich nature. Leaf-mould, manure, and a good sandy loam make an excellent compost. In this the plants root freely, and when they do this they seldom fail to do well. The warmest situation should always be chosen in which to plant Zinnias, and if planted in a bed by themselves they would be greatly improved if the soil could be thrown out, and a good depth of fermenting manure be trodden well in, replacing the soil afterwards. Both the single and the double forms of Zinnia make fine garden plants when well grown, displaying a diversity and brilliancy of colour equalled by few plants. The double forms have of late been most in request, although both the double and single varieties have been greatly improved. There is one good characteristic about the double Zinnias: they are not in some instances of such rank and unwieldy growth as the single types, and the process of dwarfing has gone hand-in-hand with that of multiplying the petals in the flowers. Careful selection also has done something in the way of inducing a better habit of growth; and it will be observed that it often happens that particular types of flower get improved both in habit and blooms at the same time. Some of the single Zinnias are very beautiful, such as the yellow, carmine, rosy-purple, scarlet, crimson, and orange. These, with the white—which is, after all, not a good white—will be always acceptable for their large showy blossoms and brilliant colours. In some parts of the country cut blooms of both double and single Zinnias are much grown for show purposes, and there is as much rivalry in the efforts to gain first prizes as in the case of Dahlias and Asters. While the Zinnia lacks the great size of the Dahlia, and the soft beauty and delicate colours of the Aster, it yet includes vivid tints and lustrous hues foreign to both these popular autumn flowers, and stands of well-grown flowers of double Zinnias are most effective on the cut flower table.

DOUBLE-FLOWERED ZINNIA (Z. HAAGEANA).

SUMMER FLOWER GARDENING.

THE latter part of May and the early part of June is always a busy time in flower gardens. Bedding-out, as it is termed, then requires full attention, and, previous to beginning to plant, everything should be in readiness, in order that the work may be done quickly when it is started and under favourable weather. It is always a safe plan to have the soil for bedding plants moderately rich and firm in the beds. Most people will, of course, please themselves as regards the way in which they make their beds, but in my opinion raised hillocks of soil are much more unsightly than flat surfaces. All the hardiest plants should be planted out first. Calceolarias may safely be put out the first week in May, and so may Pyrethrums, Carnations, and all kinds of plants not required to be grown in a strong heat in spring. Before any of the plants are put in the beds, however, each bed in the design should be roughly traced out on paper, and the position which each plant is to occupy should be marked on it. This obviates confusion at planting time, and in the case of some plants being put out before the others, such as a row of Pyrethrum round one bed and a centre of Calceolarias in another, they can always be planted in their proper places, and the right distances left to fill in with other plants. A plan thus prepared to work by is a great help at bedding-out time, but it is of still greater assistance in autumn, when the numbers of each plant required can be recorded. Where there are only a few beds to fill, and plenty to put in them, people can indulge in putting the plants in close enough for immediate effect, but in large gardens this can seldom be done. When plants are put in widely apart the soil in which they are planted should always be rich, because when they begin to grow they soon fill the beds; on the other hand, when they are put in closely together the soil should be rather poor, or the plants soon become a disorderly mass. Calceolarias, Geraniums, Verbenas, and plants of that kind, may be planted from 8 in. to 1 ft. apart in ordinary soils. For present effect some plant as close again as this, but the result in the end is not more satisfactory than in the case of wide planting. Alternantheras, Iresines, and all dwarf carpet bedding plants should be put in from 3 in. to 4 in. apart. A moderately rich soil suits these plants much better than an

excessively rich one; both growth and colour are more refined in the former than in the latter. All kinds of succulents of the half-tender type should nearly touch each other when first planted together in beds. The hardy or alpine sorts may be allowed space according to their habit of growth, but none of them should be planted too wide, as few of them, except creepers, will extend very far in one summer; and to see more space bare than is covered with plants is not desirable.

The most important matter connected with bedding-out, however, has yet to be named, and that is, hardening off the plants. I know from experience that this is often more difficult than raising or planting them out. In many places there is no scarcity of accommodation for bedding plants in early Vineries, Peach houses, &c., in February and March, but it is bringing them from these warm houses to the open beds in May without injury that requires study. Light deal frames with glass sashes are the proper places in which to harden them off, but few indeed have enough of these to meet their requirements. Many temporary erections can be put together, such as screens; but when these cannot be depended on to ward off 5° or 6° of frost and cold winds, the plants should not be placed in them until, say, the 1st of May. Previous to this they must be kept in the coolest house available. Our plan is to grow every plant as rapidly as possible up to the first week in April, and then to begin to harden off as quickly as circumstances will permit. It is, however, wrong to do this too quickly, especially if the plants have been grown in a strong heat previously. Some plants may not seem to suffer much from a sharp change such as this, but it does check them, and they often show it even after midsummer. In our own case we always harden off as soon as the plants are large enough. Plants set under the shade and shelter of trees and walls never get properly hardened off, and when they are kept there until they are taken straight to the beds and planted they suffer about as severely as planting them direct from under glass. Showery weather is a fortunate occurrence during bedding-out time; the labour which it saves is very great, and the advantage which it confers in starting the plants freely into growth at first is no small advantage at the beginning of a hot summer. When the ground is so wet as to stick to the feet boards should be used in planting. As each bed is planted the Dutch hoe should be run carefully between the plants, leaving the surface neat, level, and free from large stones. This should be done whether the soil be wet or dry. When the plants have to be turned out during dry weather they should be watered two or three days after planting; one good watering at that time will do more good than damping the surface every day for two months. Tender plants of a sub-tropical character should be planted last; and careful and gradual hardening off is especially necessary in their case, as a check to them at first often makes them unsightly during the whole season. Surplus plants of all kinds should never be thrown away when a spare corner can be found in which to plant them, for they produce cuttings in autumn and save the bedding plants, which is no small consideration, as many flower gardens are much disfigured by half of the plants being cut away for cuttings just when they are at their best. C.

French Lavender (Santolina incana).—This is one of the most useful of plants for forming edgings or divisional lines, and, being of a whitish-grey tint, it may be employed in many varying combinations. Its habit of growth is neat and compact, and, being hardy, it especially commends itself to those who have but a limited amount of glass structures. I put some cuttings of it in under hand-glasses or lights in September which will make excellent little bushy plants for furnishing beds this spring. By having a good supply of this, and such plants as Violas, Polemonium cœruleum, Golden Thyme, and similar plants, bedding-out, as it is called, becomes a more reasonable affair than when all the subjects employed are tender.—J.

Sowing Sweet Peas.—Sowing these where they are to bloom is much to be preferred to sowing them in pots or boxes; and if I were asked to name a time at which to sow them, I should say the middle of March, if a good long season of bloom be wanted. Last year I sowed at the time just named in the open ground, and also a few in pots, for the sake of experiment, in soil well prepared. Those in pots I put under glass, and when up hardened them off in a cold box pit, afterwards planting them out beside the others. Those sown in the open

Zinnia Darwini compacta.

ground commenced blooming as soon as those from pots, were much stronger, yielded much the largest quantity of bloom, and continued longer in that condition; in fact, they bloomed till the flowers were killed by frost. I find that if one wants them to bloom for a long time continuously, it is a good plan to cut off any pods that may form on them as soon as they are visible, as the pods if left on the plants exhaust them, and they soon cease blooming profusely.—C. F.

Dwarf Roses for Growing in Borders.—Dwarf Roses may be conveniently used in the formation of borders, as well as in beds and round baskets, or on the edges of clumps. Such borders are remarkable, not only for the abundance of flowers with which they are covered during the whole season, but also for the variety of colours which may be obtained by grouping different kinds together, as well as for the ease with which this sort of Rose is cultivated. All that is necessary is to prune the trees so as to induce them, if possible, to throw out new shoots from their base which will cover the whole of the soil beneath them. To make a Rose border, several parallel or concentric lines are planted, according to the shape of the bed. The Roses are about 4 in. from each other on each row, the rows being 8 in. apart. Less than three rows should not be planted if we wish to obtain a happy effect; we can, however, increase that number, according to the result we desire to obtain. By graduating the height of the plants from the first row to the last, so that they gradually increase in size, or else so that they increase so far as the middle of the bed, and then decrease to the other side, we obtain a bed of single or double slope as we please. The first form is most suitable for the borders of shrubberies, the second for open beds or baskets. We give below the names of those varieties which are most suitable for growing in borders. They must be planted according to their height, the smallest in front:—1. Laurence's Glory, very small flower, crimson-purple; 3. White Pompon; 3. Pompon bijou, light pink; 4. Pumila, a variety of the Noisette, white; 5, Double multiflora, globular flowers, pink; 6. La Désirée, bright pink; 7. De Chartres, half double, delicate pink.—J. L.

Propagating Pansies.—It is an easy process to raise Pansies from cuttings during the summer. My plan is to make a bed under a north wall, by using pieces of board 1 ft. in width, and then putting in at the bottom a good layer of brick rubbish; on this I place some pieces of turf, fill in some rough soil, and finally add, as a surface 2 in. in depth, a good open soil, with plenty of leaf-mould and sand in it, and press it down rather firmly before placing the cuttings in it. I select the young growth thrown up from the roots of the plants out of which to make the cuttings, and they are put into the bed some ¾ in. in depth, about 1 in. apart in the rows, and the rows 1½ in. asunder. The cuttings are pressed firmly into the soil, and a good sprinkling of water is given them. Keep the bed moist and cool, and shade it from the sun, and there will be no difficulty in striking cuttings and in getting fine young stocky plants for spring use. When the spring plants are lifted, at the time the beds are cleared for the summer display, they should be cut close down, and then planted in some spare spot, using the siftings of the potting bench to plant them in, and place about them. They will soon begin to make a free growth, and will bloom in the autumn. I now reach the time when the method of getting plants for summer flowering must be pointed out. I obtain them from the plants lifted in the spring and planted out, or just divided. In September I lift a few of the roots, pull them to pieces, and a large number of the young shoots thrown up from the roots will be found to have rooted. A number of these are selected, and planted out in a carefully-prepared bed for the winter, and by the early part of May they will be good tufts, and will throw up flowers. It is better to do this than to trust to the plants used in spring to carry one through the winter; as some sorts will stand well, while others fail, and then there are blanks in the bed.—D.

Perpetual Carnations in Open Borders.—Having a large stock of these, and relying on young plants for winter blooming, we last spring planted out in mixed borders a quantity of the best varieties. They soon made flowering shoots in abundance, and during the summer and autumn months their blossoms proved very acceptable. These Carnations, therefore, are desirable plants for those who appreciate cut flowers during winter, and who have but a limited amount of heated glass structures; for, although they expand their blooms more readily in a temperature of from 50° to 55°, they will yield satisfactory results in cool houses, and even out-of-doors.—J.

Begonias in the Flower Garden.—We had five beds of these last year, and nothing could have been more satisfactory; all were seedlings except one bed, which consisted of B. Weltoniensis, and this variety proved very suitable for such purposes; being of rather a rigid growth, it ought to be planted pretty thickly. Anyone contemplating trying the culture of these plants should procure a packet of seed from some nurseryman who holds a good collection of them, and if a little care be bestowed on sowing, it is astonishing how many plants can be raised from a 2s. 6d. packet. I had over 240 last season from one packet; and many beautiful flowers, both single and double, were the result.—A. H.

Variegated Jacob's Ladder.—This was one of our best plants for edgings to borders and beds last season. It is perfectly hardy, even in Scotland, and may be propagated from cuttings with but little trouble, though it strikes root but slowly. Its botanical name is Polemonium cœruleum variegatum.—B.

Auriculas Out-of-doors.—We grew these from seed last year, and planted them out in the open ground in October, where they have remained all through the winter with no protection from frost, though the crowns were kept from snow and rain by a small piece of glass

supported by a brick sloped over them, and they have now been in bud for some time. Last week the first blossom was fully expanded, and many more will soon be out.—A. E. A., *Southampton.*

IMPROVING LAWNS.

Now is a much better time to alter, renovate, or improve lawns than further on, when the Grass is in full growth. Doing anything then very often spoils the lawn for the best part of the season; but if done now it will be in fine order by the beginning of the summer, and will remain good throughout the season. No lawn will ever be found to remain good for any length of time that has not been well made at first. A good firm foundation, and not less than 3 in. or 4 in. of good soil for the Grass to grow in, will keep a lawn always in order. Sometimes there are holes which gradually sink here and there in different parts of the Grass. In that case the turf should now be cut, and either lifted or folded back from these parts. A quantity of good soil should be put in to fill up the hole to the surrounding level, and the turf should be put over again, and beaten down firmly. Edges of turf near walks which have become ragged and broken should be taken up altogether, and fresh turf put down. The edge turf should be at least 6 in. wide, and sound and firm. Those making new lawns with seed should always try and get as much good turf as will make up the edges. This keeps the whole together, as it were, and always makes a good finish. In extensive lawns there is seldom any attempt made to dig out or exterminate the Daisies; but in small places they are objectionable, and attempts are generally made to dig them out or kill them in other ways. Many never think of doing this, however, until they are in full bloom in the middle of the season, and by digging them out then holes and bare spots are left unsightly on the lawns. To avoid this, now is the time to dig out all such. After doing so, level the holes up firmly with some good soil, and sow a little of the seed advertised as "lawn mixture" over them. Where the Grass is thin and poor-looking all over, a little fine rich soil should be spread over it, and a thin sprinkling of seed should be sown over that. By May the new soil will have become thoroughly incorporated with the old Grass, and the plants from the new seed will soon combine with the old to make a charming lawn. Where Moss has taken possession of most of the Grass, a thin sprinkling of lime should be spread over it; and soot used in the same way has the power of giving the Grass a rich pleasing deep green shade. Wood ashes, too, may be used in the same way with much advantage. All these are better applied separately, as lime robs soot, &c., of its goodness. Lawns which want no fresh turf or seed should be brushed over firmly with a good broom, to clear off all worm casts and such like; then roll them over two or three times to make them firm and smooth for the Grass-cutter. A wet day, or when the ground is very moist, is the best time to roll, as the ground can be worked down more smoothly then. Verges or edges of Grass should not be cut every year, as this soon widens the walks, and a deep raw edge looks unsightly. Cut them once straight, then keep them so by merely straightening the bulged-out parts afterwards.—C.

Worms in Lawns.—Worms instinctively look for moisure. In wet weather they may be found at night by scores on the surface of the lawn. Last year, after a fortnight's heavy rain, I treated my lawn to a dose of lime water, by stirring up a very small handful of Irish lime in each gallon of water, poured the solution on the grass without a rose, and picked up the worms as they came to the surface. I filled a 7-in. pot twice with the proceeds in the shape of worms, then rolled the green; and on the following day the smaller and weaker worms were lying dead in hundreds on the surface. The work occupied a whole day, but the green has been beautiful a whole year. The larger worms come up in from one to seven minutes after the application, and must be patiently picked up as they rise; consequently only a few square yards of surface must be treated at a time unless there are plenty of helping hands and sharp eyes. The tar water which is got from the wells of gas works is also effectual in clearing a green, but it is difficult to hit upon the strength to which to reduce it. It seems to kill the worms outright, and from its chemical composition it will nourish the Grass. Probably one part in six or seven of water will suffice.—M. D.

PLANTING OUT WINTER-FLOWERING PLANTS DURING SUMMER.

I do not wish to find fault with those who adopt and recommend growing such plants as the berry-bearing Solanums, Salvias, Eupatoriums, Arum Lilies, Deutzias, Dielytras, Libonias, &c., in pots all the summer, as I have no doubt success may be obtained in that way, but, according to my opinion, at a greater cost for labour, &c., than when they are planted out. Part of the success of planting such plants as those above mentioned in the open air in summer depends upon the site selected for them. If planted in very rich land they are apt to become gross, and therefore do not lift well in autumn; often they lose their lower leaves, and do not flower so freely afterwards. Again, if the pinching or stopping of the growing shoots be neglected, a straggling habit is engendered, which is difficult afterwards to put right. The pinching should be done when the removal of just the terminal bud will suffice to give the requisite bushy habit. If delayed until several inches of wood have to be pinched off, there is a waste of power, as a greater check than is necessary is given, and, in our short summers, time lost is never recovered. Assuming that an open-air sunny position, where the ground had been some time previously well worked, is available, and that

Striped Zinnia (Z. Darwini vittata).

the plants intended to be put out are brought forward and regularly hardened off, about the end of May is a suitable time to plant. In allotting space to each species, the size which they are likely to reach should be considered, as it is better to have a few well-grown plants than a greater number of ill-developed ones.

Where only medium or small-sized plants are required, cuttings struck early in the season—say now—will, under good management, make good specimens, but when large plants for conservatory decoration are desired, then one, two, or even three-year-old plants, of some kinds, will be more suitable. If any of these be cut well back when the flowering is over, or say about April, and planted out about the end of May or beginning of June, they will make handsome well-furnished bushes for the following winter. It will be very beneficial to mulch the surface of the ground amongst and around the plants as soon as they are planted. Mulching tends to keep the roots close at home and near the surface, which will be found to be of immense advantage to them when the time comes for lifting and potting them, as the less the roots are cut about then the better; and, for the same reason, in very dry hot weather water should be given when necessary, but if well mulched water will not often be required. The period for lifting may vary a little, according to situation, but in most places the middle of September will be as late as they should remain in the beds; and about ten days previous to lifting, the roots should be cut round with a spade at varying distances from the stem, according to the size of the plant and the size of pot they are to occupy, leaving as much root as possible.

If the plants are growing in rich soil, and at any time show symptons of grossness, a spade thrust into the ground at a suitable distance from the stem, so as to sever some of the roots, will correct this, and ensure the production of wood which will be fertile as regards blossoms. This plan of checking the roots a little with the spade will not take up much time, and may be resorted to when necessary during the growing season. It will promote a larger root developement close at home, which will be found to be of great benefit when the plants are lifted. After they are potted into suitable-sized pots (which should not be too large) they should be placed in a shady position for a few days, still keeping them in the open air, as the longer they can remain in the open air, if safe from frost, the better, as it will enable them to become well established before being housed; and they will be less likely to lose foliage than if lifted and moved into a drier and warmer atmosphere at once, before the roots have fairly recovered their power of supplying the wants of the plants. The advantages of planting out are at least twofold—it saves labour, and secures a better development if fairly carried out. Neither a very rich soil nor yet a poor one is so good as one of medium quality. Where the soil is poor and sandy, a little better soil should be placed round the roots of the plants when turned out.

E. D. Y.

COLD PLANT HOUSES.

Do we make as much of cold plant houses as is possible? I am afraid not. Heated structures are now fashionable, and a really cold plant house is somewhat of a rarity, and a well-stocked one still more uncommon. A cold greenhouse in a sheltered, sunny nook near the dwelling-house forms, or may be made to form, an extra apartment of much interest; and it is quite possible to have it stocked with attractive plants all the year round. For winter and spring-flowering bulbs and herbaceous plants such a house is invaluable, and during summer and autumn it may easily be rendered gay by means of flowering shrubs, annuals, and bulbs of many kinds. No day in the year need such a structure be dull or uninteresting. There are hundreds of species of plants that are so nearly hardy that a cold frame, or even a hand-light, will protect them from the vagaries of our climate; and such as these would be quite at home in a cold plant house. In reference to this matter, a lady correspondent has lately written to me as follows:—

"For several years I have been trying to find out of what a cold greenhouse is capable, and people are sometimes surprised to see what can be done in the way of interesting and even showy plants without much heat. Some Oxalises are admirable for early spring. Just now the early Primulas—denticulata, pulcherrima, and purpurea—which I raised myself from seed, are lovely. Orobus vernus is very pretty, and living, as it does, in the same pot year after year, it gives one no trouble. Myosotis dissitiflora is also very charming, and Saxifraga ciliata has pleased me greatly. Hyacinths and Narcissi are not so early or satisfactory as usual, but are now coming into flower very fast. I wish very much you could be persuaded to take up the subject. Mr. Grieve, recently writing in Gardening, speaks of unheated greenhouses being unsatisfactory; but I do not think they need be so if one does not attempt too much; and heated plant-houses are often so prejudicial to health that ladies who are at all delicate are debarred from a most healthful and interesting occupation on that account alone. On the other hand, unheated structures supply the shelter both to the plants and their owners which is so desirable in winter. Two potfuls of Crocus Imperati, sent me by the Rev. H. Harpur Crewe, gave me this winter more pleasure than I can say, lasting quite a month. In a warm house they would have been drawn up and almost ruined for another season; and so with many other hardy plants whose natural blooming time is mid-winter. I should very much like to see the subject discussed in the gardening papers, and thus to learn more of the hardy plants suitable for the purpose."

What might we not do in such houses with such plants as the variegated Yuccas, Agaves, and Aloes, Ruscus androgynus, Camellias, Azaleas, Arum Lilies, Tree Carnations, Ericas, Epacrises, and the finer kinds of Rhododendrons,

including all the Sikkim-Himalayan kinds, many of them the finest of foliaged plants, with flowers as large as those of Lilies, and fragrant withal! Then come the hardy and half-hardy aquatics, Hippeastrums, Blandfordias, and many Cycads and Ferns, such as Adiantum pedatum; and Orchids, such as Orchis foliosa, O. latifolia, O. maculata in variety, Cypripedium spectabile, and others. The rosy and the white Water Lily should also have a place in such a house; and Moutan Pæonies, Dielytra, and the dwarf tuberous Spiræas, Primulas, and Auriculas in variety, should have a corner devoted to them, or a cold frame from which they may be brought in to bloom. What a little garden might be made of a cold house by training Clematis indivisa, Lapagerias, and Fuchsias on the roof, planting Camellias of different sorts in a central bed, keeping the side stages for portable pot plants. So much for a general cold plant structure; but the specialist might build a new or alter an existing house for hardy aquatics, of which there are many—Thalia dealbata, Trapa, Richardias, Nymphæas, Pontederias, and many more. A hot, dry structure would do for succulent plants in variety, or a cool, moist, shady one for Ferns. I am merely jotting down suggestions in the hope that others may fill in the practical details. Those who do not believe in absolutely cold plant houses might do well to tell us of their disadvantages; but most welcome will be the contributions of those who will give us the results of their experience in their management. I may just allude to the fine Temperate House at Kew, which is but slightly heated, and yet the results are very satisfying to many. F. W. B.

VEGETABLES.

Scarlet Runners.—This useful vegetable, which has long been a favourite, still retains its well-merited popularity. The artisan who has only a small yard for a garden often, with considerable labour and ingenuity, improvises a bed for Scarlet Runners, and so not only secures a frequent dish of his favourite vegetable—rendered all the sweeter from the trouble incurred in its production—but clothes and beautifies his back premises at the same time. As a vegetable for small gardens this takes precedence of the Pea, and although Scarlet Runners have been cultivated in positions where most other vegetables would fail, yet at the same time scarcely any crop makes a better return for liberal treatment. Depth of soil and plenty of manure are important matters, and the benefits that accrue from autumn and winter culture need not now be enlarged upon, having been so often referred to in these pages. Commence planting from the first to the middle of May, according to the position and latitude of the place. The young plants are very tender and early-sown crops are often ruined by spring frosts. Plant in drills 6 in. or 7 in. wide, two rows in each drill close to the sides, and the Beans should be planted 6 in. apart in the rows. Draw the drills with a hoe about 3 in. deep, the same as for late Marrow Peas. The rows give a larger crop if they can be isolated, with dwarf vegetables between them. If placed parallel to each other they should not be less than 5ft. apart, and even more space would be preferable. The second crop should be planted about the first or second week in June; and although in all probability the first crop, if properly managed, will continue bearing till cut off by frost in autumn, yet if in the event of a dry, hot summer it should be checked in the midst of its bearing, it is always a good plan to make two sowings. They should be earthed up and staked before the plants begin to run, and the strongest sticks that can be obtained should be reserved, especially if the situation be exposed, as the wind has considerable power upon their thick, close growth. It is important that the Beans should be gathered as soon as fit for use, especially during the early part of the season, as seed-bearing tends to exhaust the plants and stop the production. Later on in the season, when the nights are longer, should it be desired, a few pods may be left to produce ripe seeds without doing so much injury. In small gardens, where land is valuable, they may be planted in circles 2 ft. or so in diameter, with about a dozen Beans round the circumference. The patches may either be grouped together or be placed along the sides of a path convenient of access—of course in both cases leaving sufficient room for the free admission of light and air to circulate between the patches. In some cottage gardens I know this is rather a favourite way of planting them, and it is considered they are more productive when so treated. The strong leading shoots, when about 4 ft. high, should be stopped, and again when they reach the tops of the sticks, which should be 6 ft. high if possible. This stopping strengthens the plants, keeps them at home, and leads to great productiveness. In hot weather mulching is very beneficial, and two or three good soakings of water during a sudden drought when the plants are in flower will assist the fertilisation and save the crop. Scarlet Runners may also be grown without sticks by adopting a system of close pinching; but in small gardens some mode of training should be adopted, as the space upwards adds nothing to the rent, no matter how densely it may be occupied.—H.

The Currant Tomato.—This is very ornamental when grown in pots. It requires exactly the same treatment as other kinds of the

The Currant Tomato.

Tomato. The seed should be sown at once in a warm house or frame. When large enough the seedlings should be potted off singly into small pots, and shifted on as becomes necessary. The best soil is turfy loam, with enough sand added to make it porous. Too much wood should not be allowed; and those shoots which remain should, when sufficient fruit is set on them, be stopped by pinching out their growing points. When the fruit is swelling occasional doses of liquid-manure will be of benefit. This Tomato may be used for culinary purposes, and it is especially suitable for pickles.

One or two Plain Facts respecting Potatoes.—A great authority on Potato culture tells us that "handsome seed begets handsome Potatoes"—an assertion I am not prepared to contradict; but I am prepared to say that ugly seed also begets handsome Potatoes. Last season, wishing to increase my stock of Schoolmaster, I picked all the best-looking ones out and planted them side by side with some of the worst-shaped seed I ever saw; nevertheless in lifting them I could discern no difference, all being alike handsome. As regards cut and whole Potatoes, I planted half an acre cut and half an acre whole, so that I might prove which was the best plan, but on digging up the produce there were six of one and half-a-dozen of the other.—R. G. B.

PARSNIPS A SUBSTITUTE FOR POTATOES.

ONE would have thought that, with the great uncertainty attaching to the Potato crop, Parsnips would have come more into requisition than they appear to have done up to the present, as they are not only more nutritive than Potatoes, but they will grow and flourish in soils and situations in which the latter would become diseased and worthless for eating. Irish people seem to depend almost entirely on Potatoes; but if they would only turn their attention more to Parsnip growing, much of their distress during the past winter might have been averted, as the yield in weight from such a summer as last would have been something enormous, the wet having just suited Parsnips and swelled their roots out to a considerable extent. Although they may not come quite so large during a dry season, they never fail, and are therefore a most profitable crop to grow either in fields or gardens; for should the whole of them not be required for use as vegetables, they are valuable for cattle feeding, for which they are largely cultivated in Guernsey and Jersey. Many years ago Potatoes did not come much into consumption, but now a dinner is not considered complete without them; and, after a time, when prejudice has worn away a little, it may be so with Parsnips. The flavour is considered objectionable by some; but by daily use one soon acquires a liking for them, and if we have a few more turns of such a scarcity of vegetables as we have had for many months past, we shall train our palates in such a way that Parsnips will not come amiss to us.

To grow their roots well, and get them fine and long, the soil must be thoroughly stirred to a good depth, that the root may have a fair chance to run down; for if the earth is hard and lumpy fangs are induced, and these spoil the shape and symmetry of the root, and render it unfit for the kitchen. Fresh rank manure has much the same effect, and therefore ground intended for Parsnips should be free from this; and if it can be arranged for them to follow some other non-exhaustive crop without giving manure, all the better, as the skin is sure to be clearer and whiter than it would be if grown in land full of rich matter. Rather than sow in such, it is advisable to give a dressing of guano and soot after the plants are up, or a mixture of the two, as so combined they are a most excellent stimulant, and one that is most obnoxious to wireworms and grubs, both of which are great enemies to root crops like the Parsnip, as they nip through the main roots and cause them to flag. Some of the best cultivators of Parsnips sow in September, but the objection to this plan is that it is a difficult matter to keep the ground clean for such a length of time among the growing plants, as weeds have so much chance to get up and ahead of them before anything can be done to check them by the use of the hoe. Taking this into consideration, I prefer the middle of March, or as soon after as the soil is in fit condition to work on, there being nothing gained by hurrying them in when it is wet and unfavourable. To afford plenty of room the drills to sow in should be at least 15 in. apart, and the plants, when up, thinned out to 1 ft. asunder, which will allow space for the full spread of the foliage, without which the Parsnips cannot attain to a large size or ripen up so well in the autumn; and on this much of their quality depends. Many take the roots up and store them for the market; but it will be found that the flavour is greatly improved by the action of frost, which has a sweetening and mellowing effect, doing away in a great measnre with the strong taste some eaters of Parsnips object to. For growing in fields, it takes about 5 lb. of seed to the acre: and now that the price of corn is so low, it may be worth while for farmers to try these, and keep more stock, as the feeding value of Parsnips is unquestionable, and they would also make a remunerative return in the market. The Guernsey and Hollow Crown are the largest and best for field culture, but the Student is in most esteem for gardens; and this latter is of good form, and its cooking qualities are excellent. S. D.

House and Window Gardening.

GENERAL TREATMENT OF WINDOW PLANTS.

It will naturally be understood that cleanliness is of the first importance to plant life. Leaves breathe, as it were, through their pores, and if these be choked by impurities of any kind, the functions of the plant are in a manner paralysed. The more confined the atmosphere the greater need is there for frequently washing and syringing. All plain, hard-foliaged kinds should be well sponged, using plenty of clean tepid water. Ferns, Mosses, &c., may be gently but thoroughly syringed, taking care that the under surface of the foliage is well cleaned. Insects often make their appearance, and must be kept under either by brushing them off with a soft brush or by means of fumigation. The latter is the most effective method, although if the stitch-in-time principal be acted upon and the first insects destroyed, there will seldom be any need for it; should a plant, however, become badly infested, place it under a tub and fill the same with Tobacco smoke. Two applications at the interval of a few days will generally suffice to clear them all off. When we come to watering we touch the most difficult part of our subject. It is utterly impossible to lay down hard-and-fast rules: the attempt to do so would merely result in disastrous failure; nothing but practice can give proficiency in this branch of plant culture. The great point to be kept in view is, that in winter water is merely required to maintain life; whereas in summer, when the functions are active and growth progressing, enough must be given not only to supply waste, but to allow of the extension and formation of new tissues. Were these facts kept constantly in mind, there would not be many disasters arise from over-watering. In dull, sunless weather, let each plant dry out thoroughly, and then give just enough to well moisten the ball of earth. In a hot parching time this care is not so needful; if the roots are healthy, and the plant growing freely, copious and frequent waterings must be the rule. These general rules will form a basis upon which the grower may safely work. They will, however, have to be varied and modified according to circumstances and the plants cultivated, but for the acquirement of this knowledge he must rely upon constant practice and unremitting attention. In the matter of ventilation, be careful to avoid cutting draughts; much harm is often done by injudicious air-giving. Do not, either, run into the common error of turning your plants out upon the doorsteps or balconies in weather which, although sunny, may yet be of a chilling nature. Harden gradually on the approach of spring by increasing the amount of air, and only turn them out-of-doors on mild moist days. A safe rule is to be guided by one's own feelings; if the atmosphere be congenial to the human frame it will be beneficial to plant life, and *vice versa*. That, at least, is the conclusion at which I have arrived.

Potting and Propagating.

Many who grow window plants make a point of getting them shifted by a professional cultivator. This is, however, by no means necessary, and is wrong in principle, as the nature of a plant is but imperfectly understood if its root action cannot be observed. I would advise that the soil be purchased at a nurseryman's, stating for what kind of plant it is required. Be careful never to give large shifts, and see that your soil is well sanded and not too rich; any little deficiency in nutriment can easily be supplied by a top-dressing of any of the concentrated manures. For Ferns and delicate-rooted subjects allow plenty of drainage; in fact, all kinds of plants grown in rooms should be amply provided for in this respect. Nothing can be more injurious than the stoppage of the drainage, and to secure immunity from injury in this respect each plant should be examined at the commencement of the winter, and fresh drainage given, if found necessary, using some good clean potsherds or broken charcoal for that purpose. There is no reason why window gardeners should not try their hands at propagating; it is amusing, and greater pleasure is derived from the culture of home-struck plants than from those which have to be bought. Most of the so-called soft-wooded plants may be increased with ease, and if a few cuttings be put in every year, they will supply the place of plants which get too large. The appliances necessary will consist merely of a few bell-glasses, some soil of a light description, and some silver sand. Fill the pots to within 2 in. of the rim with soil, and finish off with sand, making the pot quite full. The pot should be filled about one-third of its depth with drainage. The cuttings are inserted in the sand and kept covered with the bell-glass until rooted. Fuchsias, Heliotropes, Verbenas, Lobelias &c., may all be struck in this manner in an ordinary living room. Pelargoniums only will need no covering. Put each cutting in a small pot; it will root freely enough. Seeds of annuals may also be raised by sowing in a pot filled to within 1 in. of the rim, and covered with a piece of glass until fairly up. I have here indicated comparatively little of what may be done in the way of window gardening, but enough, I think, to enable even beginners to try the undertaking with a fair prospect of success, I trust that they may not be daunted by a few failures; for, permit me to add, in this as in every other branch of gardening, there is no royal road to success. J. C.

The India-rubber Plant (Ficus elastica).—Of all plants grown for their foliage for market purposes this is the most popular. It is one of the best London window plants in existence,

The India-rubber Plant.

and a plant which will grow and keep healthy in the same pot for years if well supplied with water. Nearly every florist around London grows as many plants of it as he has room for, and yet it keeps up its price in the market. It is propagated by means of young tops of growing shoots, which are taken off and struck in the same way as those of Dracænas, old plants being generally grown to provide them. In windows the leaves should be frequently sponged. The plants require light and air and plenty of water. If placed in a draughty room, their leaves turn yellow.

Vitality of Seeds.—Five years ago, when on the passage between Liverpool and Bordeaux, I had a packet of Hunt's Sweet William seed given to me by one of my passengers. Three weeks ago I sowed it, without the least hope of its germinating. To my surprise, I find that the seeds have burst, and are doing well.—Captain R. M. Bell.

Destroying Gooseberry Caterpillar.—The simplest method I could devise last summer to destroy these pests was to fill a common hand-bowl half full of boiling water, and, holding it under the tree with one hand, nip off such leaves, or a portion, as were attacked with a pair of scissors, and let the caterpillars fall into the bath. I counted a quarter of an hour's work one time, and found I had 260 carcases.—J. Hiam.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 29.—Potting off Cyclamens, Lantanas, Globe Amarantus, the last of the Dahlias; sowing White Cape and Miller's Late Broccoli, and French Beans; planting Violets and Lettuces from frames, and pricking off herbaceous Calceolarias, Ice-plants, and Sweet Basil; putting in cuttings of Alternantheras; also another batch of Pinks; syringing Apple trees in orchard with alum-water to kill blight; putting strings over Peas to keep off birds; taking lights off bedding plants on all favourable opportunities; tying down Vine shoots, and keeping Muscats in flower at 70° at night and 95° by day; sowing G. F. Wilson, Veitch's Perfection, and Giant Emerald Marrow Peas; also Mammoth and Long Pod Beans; pricking off Asters, Poppies, Stocks, and Violas; potting off Verbenas, and Heliotropes; Clearing off the stumps of green Curled Kale and other Greens; manuring the ground and getting it dug up for other crops.

April 30.—Sowing Autumn Giant Cauliflower; also Autumn Self-protecting and Winter White Broccoli; putting in cuttings of Alternantheras and Coleus; removing bedding plants from pits to convenient places to harden; thinning Carrots and Radishes on early borders; renovating linings round frames; taking the guards off Peas somewhat advanced and putting them over newly-sown ones; sowing Indian Pinks and Mignonette in the flower borders; also Dianthus Heddewegi, Centaurea Cyanus, and Aubrietia purpurea and græca; planting spring-sown Cauliflowers between Asparagus beds, and Lettuces on Celery ridges; making a new bed of Keen's Seedling Strawberries with plants that had been forced; moving all Dahlias out of heat; emptying and re-filling vases with fresh soil; syringing Peach trees on walls out-of-doors with a mixture of Tobacco-water in order to keep down green and black fly; digging up and removing Winter Greens as fast as they become useless.

April 21.—Sowing another batch of Primulas and Balsams; also Brussels Sprouts, Curled Greens, Cottagers' Kale, Buda Kale, Walcheren, Backhouse's White, and Snow's Winter White Broccoli; planting Asparagus on newly-prepared beds; also more Cauliflowers, and a border of Lettuces; dipping Capsicums and Chrysanthemums infested with green fly in Tobacco-water; sowing Radishes, Mustard and Cress, French Marigolds, Celosia japonica, and Cockscombs; planting out Golden Feather Pyrethrum into rough frames; looking over Pelargoniums and other bedding plants, and stopping them where required; thinning out Lettuce plants; getting out trenches for Celery, and hoeing amongst growing crops.

April 22.—Sowing Turnips, Spinach, and Melons; potting off and looking over all Strawberries that are well set, and picking off all weak blossoms and deformed fruit; earthing-up Potatoes in frames; thinning out Turnips and hoeing amongst them; looking over French and Nectarine trees on walls and washing them with Quassia-chip water to kill green fly; sticking Peas and earthing them up a little; potting Mrs. Pollock Pelargoniums and Perilla; planting out Neapolitan Violets and hardy Azaleas; hoeing among spring flowers, thinning Turnips, and examining Rose trees for maggot; top-dressing Cucumber plants growing in large pots and tubs with rich loam; keeping Alicante Grapes that are in flower at 70° at night.

April 23.—Potting Czar Violets for blooming next spring; sowing French Beans, more Radishes, and Mustard and Cress on borders; also sowing main crop of Scorzonera and Salsafy; hoeing among growing crops; earthing up Potatoes on early borders; syringing Peach trees out-of-doors with Tobacco-water and soft soap; shifting Gnaphaliums from houses into cold pits, and giving a little artificial manure to Azaleas Camellias, Heaths, and Epacrises; making up hotbed for Pink cuttings, and staking and tying up the flower-spikes of herbaceous Calceolarias; potting off Gourds, Sweet Basil, and Marjoram; pricking off Winter White and Autumn Self-protecting and Autumn Giant Cauliflower into frames; giving all Rose trees that are infested with green fly a good washing with Quassia-chip water; looking over Cucumbers and Melons, picking off all false blossoms and stopping them where required, also fumigating them in order to kill green fly.

April 24.—Potting on ridge Cucumbers and Vegetable Marrows; rolling down gravel and turf; forking amongst early Potatoes; thinning out Spinach and tying up Lettuces; potting Anne Boleyn Pinks in a mixture of cow manure and loam; shifting young Fuchsias into 8-in. pots for conservatory decoration, and potting off Mesembryanthemums and spring-struck Heliotropes; also shaking out and re-potting standard Verbenas; sowing Paris White, Green Cos and Neapolitan Cabbage Lettuces; also Majoram and Globe Turnip; thinning fruit in Peach-house, leaving one to each shoot.

Glasshouses.

Dipladenias should have their shoots regularly trained to the strings or wires that support them, otherwise they get into a confused mass, from which it is impossible to separate them without injury. Such as are intended ultimately to bloom on trellises should not be trained on these until the young growths show a sufficient quantity of flowers, as bending the shoots down will in all probability have the effect of stopping their further extension.

Bougainvilleas.—Specimens of these in pots intended for conservatory decoration, where they will necessarily be in a lower temperature than that of the stove in which growth has been made, require special treatment in order to prepare them for this. B. glabra is by far the easiest managed and most useful for this kind of work. In order to bloom it well from the time when it is started into growth in winter or spring, the soil must never be allowed to approach a dry condition, such as would cause the leaves to flag,

even in the least, for when that occurs the shoots generally make little further progress, in which case the quantity of flowers which they produce is very much less than where vigorous uninterrupted growth has been maintained. For a like purpose the young shoots should be kept temporarily tied up in an erect position until the full complement of bloom is visible. As soon as the bracts of the earliest have got to about three-fourths their full size, and begun to attain their colour, the plants should be moved from the stove into a cooler, but not a cold, house. Here the flowers will come on slowly, and will last, after getting their full size, six or eight weeks, and they will be deeply coloured. If, in place of being treated in the manner recommended, the plants be allowed to remain in the stove until the flowers are fully matured, and then moved into cooler quarters, it usually happens that they all fall in a very short time.

Gardenias.—Any plants that have been forced into bloom early, and that have now done flowering, should be freely cut back, well cleaned from insects, and returned to the stove. As soon as growth commences they should be moved into larger pots, or, if not required to be grown to a larger size, a portion of the old soil should be shaken out, and the plants should be replaced in fresh material in the same pots which they previously occupied. The compact-growing, free-flowering G. citriodora is well deserving of cultivation; its beautifully-scented flowers are always acceptable, and its occupying so little room, compared with the stronger-growing G. florida and G. Fortunei, makes it more suitable for those whose accommodation is limited.

Allamandas.—Such of these as are grown on trellises in pots should not have the shoots trained until they show flower, but ought to be kept slightly supported in an erect position, as, if bent down, they keep on breaking out afresh. They will now bear continuously a stronger application of manure water than most plants; they should therefore not be stinted in this respect, as the stronger they get the greater profusion of flowers they will produce, assuming that last year's wood was thoroughly ripened.

Caladiums and Alocasias.—These will now be in active growth, and every encouragement should be given to free vigorous development, not by an over-lengthening of the foot-stalks, but by an endeavour to impart all the strength and substance possible to the leaves, so that, if required, the plants will be able to do service for decorative purposes in a somewhat lower temperature than that of a stove later in the season. The condition to permit of this can only be secured by allowing the plants sufficient room, keeping them near the glass, and using no more shade than is necessary to prevent the foliage being discoloured.

Marantas.—Plants that were increased by division earlier in the season will now be forming root and leaf-growth freely. Encourage a stout sturdy state of the leaves in preference to a soft extended development, which renders the plants wholly unable to bear even for a short time a temperature lower than that of a stove.

Achimenes and Gloxinias. — The earliest Achimenes will now have advanced considerably, and, whether grown in baskets or pots, give them all the light possible, so as to prevent the shoots being drawn up long and weak, for upon this depends their ability to bear an abundance of flowers. The latest started bulbs should, as soon as they are ready, be transferred to the pots or baskets in which they are intended to bloom, and treated so as to make their growth slow and strong. Gloxinias now flowering may be assisted to produce a still longer succession of bloom by giving them manure water, provided the leaves are kept in a healthy, clean condition, free from insects. Large plants intended either for home decoration or exhibition should, if possible, be set on a shelf near the roof and be allowed to come on slowly, treatment that holds good with these plants for whatever purpose they are intended and at whatever time of the year they are required to flower. Gloxinias are so accommodating that they may be had in bloom for eight months out of the twelve; but to have the flowers with the strength and substance requisite to enable them to stand without flagging on the plants when subjected to a lower temperature than that in which they have been grown, or to make them equally of use for employing in combinations of cut flowers, it is necessary that they be grown slowly and under such conditions as are here described, which give them a sturdy character, very different from the weak flabby growth of both foliage and flowers too often met with.

Winter-flowering Stove Plants.—The stock of these, including Euphorbias, Eranthemum pulchellum, Sericographis Ghiesbreghtiana, Thrysacanthus rutilans, Plumbago rosea, Jacarandas, Begonias, and Aphelandras, must have every assistance given them, so as to obtain a stout, sturdy, short-jointed condition of the plants, giving them enough pot room to ensure a plentiful supply of healthy roots, for on this depends their ability to bear the full amount of flowers of which they are capable more than upon shoot development.

Poinsettias.—Moderate sized heads of these plants on stout stems are the most generally useful. A good deal depends upon the character of the house which they are to occupy when in flower; if to do duty in a large structure intermixed with larger-sized plants, they require to be grown proportionately large; and when so managed, on stems from 4 ft. to 4½ ft. high, strong and vigorous, they will produce immense heads, such as are unobtainable from dwarf plants. Where wanted, some of the old stock should at once be started in heat and moisture for this purpose; and if any small stools exist they may be headed down to within a few inches of the surface and grown on with from one to three stems each. If liberally treated through the season they will make fine decorative objects.

Amaryllises.—For conservatory decoration, when in bloom, where they can receive a few degrees more warmth than an ordinary greenhouse affords, these are invaluable; their distinct habit, and the endless variety in shades of colour that have resulted from crossing the best species, particularly adapt them for associating with the usual plants in bloom in such structures through the spring. Whilst flowering see that they do not want for moisture, as active root growth is now also going on; and as soon as they have done blooming they should be at once placed in an intermediate temperature where they will get abundance of light and air every day when the weather is at all favourable. They succeed best in good, strong, holding loam, well rammed into the pots at the time of shifting; as compared with most other plants, they require to be under-potted as to size, though restriction in this respect must not be carried too far in the case of large bulbs that have a disposition to produce offsets, but which, unfortunately, many of the finest seedlings are slow in doing. Of all the plants in cultivation, none are perhaps more suitable for amateurs to raise from seed, or to which more interest is attached; but where crossing is attempted none but the best broad-petalled flowers with well-defined colours should be selected to breed from, and the nearer the colour at the base of the segments approaches to white, not green, the better; this latter is of importance, as it adds so much to the improved appearance of the flowers. Seedlings are generally kept in the pans in which they have been sown, or to which they have been transferred, until they have attained considerable strength, as if potted singly before the bulbs have got some size, with a proportionate amount of roots, they would only bear pots so small that the little soil which they hold would be continually liable to get dry through the growing season, a condition which should never be allowed to occur. One of the great advantages that Amaryllises present to the cultivator is the little space which they occupy whilst making their growth, and during the time they are at rest they can be placed where few other plants would do at all.

Celosia pyramidalis.—This is one of the most useful decorative plants that can be grown; its elegant erect habit affords such a contrast to the generality of other plants, that it is never in the wrong place associated with anything else. If a little seed be now sown and treated in the way in which ordinary Cockscombs are found to succeed, the plants will do well. Like the Cockscomb, it is very subject to the attacks of red spider, which, if allowed to become established, will ruin the appearance of the plants. A free use of the syringe on the under-sides of the leaves is necessary in order to keep them clean.

Flower Garden.

Auriculas.—The named varieties belonging to the florist section are now in full bloom, and this must be preserved for as long a period as possible. Thin out all badly-marked or badly-shaped pips; also thin the flowers of all trusses that have too many pips. Small offsets potted last autumn or early this year must now be potted off, placing the plants in a frame behind a north wall; give them plenty of air, removing the lights altogether in fine weather. See that plants of alpines in beds are attended to, the beds kept clear of weeds, and the surface soil stirred if necessary.

Dahlias.—These must not be too severely exposed to the weather as yet. If the plants are in cold frames it will not answer to expose them to the frost at night with only the glass between them and the open air. Place mats over the frames at night. Remove any plants that are established into the frames, but they must not be placed in frames from a warm forcing house all at once. The plants require plenty of air, when the weather is fine removing the lights altogether. If the best results are to be obtained sufficient space must be allowed between the plants to allow of the free development of the leaves.

Gladioli.—Still continue to plant out a few of these on favourable occasions. If possible the ground should be dry, and it is desirable that it should be well pulverised by turning the surface over when it is in a dry state. Seeds may still be sown, but to ensure the flowering of the plants next year they must be sown on a hotbed. The seeds will germinate in a fortnight, after which air may be more freely admitted to them. By-and-by, when the weather is fine, they may be fully exposed with the lights off. Freely supply the pots with water when the seedlings are in full growth. Run the hoe through amongst the plants that have appeared above ground. The rough, dry surface is a slight protection from frost, but when the collection is but small it is easy to invert a flower pot over each plant at night, removing it in the morning.

Phloxes, and indeed all similar herbaceous plants grown to flower in pots, may now be placed in a favourable position out-of-doors. What the largest proportion of these require are generous supplies of water at the roots and rich potting material for them to work into; and do not allow the plants to be root-bound in the small pots in which they are wintered. Place sticks to the young growths, as they easily snap off at the surface of the soil.

Polyanthuses. — These are now in full beauty, and are very much admired. This is a free, fast-rooting plant, and therefore requires considerable supplies of water at the roots; the frames in which the plants are growing should face the north, but even here it is necessary to shade. Seedlings raised from seeds sown as soon as they were ripe last year should now be planted out in a bed of rich soil behind a wall or a hedge.

Pansies and other small-growing plants of that kind in frames require attention as regards keeping the leaves free from insect pests. A close atmosphere is conducive to the spread of insect pests. All such plants continue in the most healthy condition when air can be freely administered. Should the flowers be required for any particular occasion, it is best to pick all the open blooms from the plants two weeks previous to that date.

Fruit.

Vines.—In some instances early Grapes will now be colouring, a critical stage in the case of Vines that have in previous years been cropped too heavily, or that have not had a sufficiency of water during the present season, conditions either of which tends to the production of shanked berries. If there be any apprehension on this score it will be well to apply the remedy even before the disease shows itself, and that is to water liberally with tepid water, and mulch immediately afterwards with litter or old Mushroom-bed manure, in order to retain the moisture and prevent the necessity of watering again till the fruit is cut; and should there be any misgivings as to the crop being too heavy, it will be better to cut off a dozen bunches at

once than run the risk of three times that number shanking. Good colour and finish can only be attained by free and regular ventilation. Cold currents of air must be avoided, but a gentle circulation of rarefied air is now a necessity night and day. This, of course, implies firing, but that must only be done to a reasonable extent, for the bloom on the berries will be denser if the maximum temperature does not exceed 65°. The air moisture should be lessened, but not entirely withdrawn, or red spider will soon get the mastery. Pot Vines require the self-same treatment, with the addition of more frequent waterings. Late Vineries will now require a large amount of attention in the way of tying down, stopping, and regulating the shoots; and the atmosphere cannot well be too humid or the house be shut up with too much sun-heat from the present time till the flowers open, when a more buoyant and drier atmosphere should be maintained. Do not stop the shoots according to the orthodox fashion, viz., at one joint beyond the bunch, but according to the trellis space there may be naked, all of which should be covered, but not crowded. Any Vines yet to be planted should have early attention, for though they thrive when planted at any season, April may be considered the best time for planting them.

Kitchen Garden.

Beds or plots of Asparagus should now have a dressing of soot, salt, or wood ashes, which will both fertilise the soil and keep off slugs from the young shoots now emerging from the soil. New plots may now be planted in rows 3 ft. apart and 2 ft. plant from plant in the row. The old system of forming beds and covering them up annually with fresh soil should be allowed to become obsolete. If grown on the flat system and in regular lines, and the soil be kept stirred during the growing season, and surface-dressed in winter with either a little fresh soil, rotten manuré, salt, or burnt ashes from the refuse-heap, the best of Asparagus will be the result. Judging from plantations in the neighbourhood of Paris, plenty of space between the rows seems to be the aim of French growers, and apparently the reason why they excel us in the culture of this esculent. Seeds of it may also be sown for transplantation next year. Seakale, Rhubarb, and Horseradish that have yet to be planted cannot longer be delayed if they are to be satisfactory in growth and produce; and the same remark applies to Potatoes, all of which ought now to be in the ground; earth up early border kinds, and keep litter or Bracken at hand for covering when frost seems imminent. Thin out, earth up, and stake advancing crops of Peas. Thin out Parsnips to 8 in. apart as soon as the seedlings can be handled; stir the soil between the rows when dry, and also between all other growing crops, such as Parsley, Cabbage, Lettuce, and winter Onions. A general sowing of Kales, Broccoli, and Savoys may now be made; also a last sowing of Autumn Giant Cauliflower. The usual routine work will now consist of making frequent and regular sowings of summer vegetables and salads, such as Lettuces, small Salads, Radishes, Spinach, Turnips, Peas, and French Beans. Keep walks, alleys, and edgings neat and trim, and the ground between all crops well stirred, both for the destruction of weeds and for the advancement of growth.

Celery sown in heat, as recommended some time since, will shortly be large enough for pricking out. Where it is required for use as early as obtainable, there should be prepared for it a slight hotbed, consisting of about 18 in. of fermenting manure and half rotten leaves. On this place a two or three-light frame, with 10-in. of rich soil, into which put the plants 1 ft. apart each way, giving a little water, afterwards putting on the lights, which keep close for a few days, until the roots take hold of the soil; if the weather be sunny, shade in the middle of the day. As soon as growth has fairly commenced, give plenty of air, to prevent the plants drawing up weakly; and, if well attended to as regards water, they will progress rapidly. The lights should not be altogether dispensed with until all fear of frost is over; every alternate plant may then be removed with a good ball of earth and turned out into a well-prepared trench, leaving the remainder on the bed on which they have been grown, and when large enough earthing up with light soil brought in for the purpose. By this means those who want Celery very early can have it in good condition by midsummer, but, of course, not large. It will be succeeded by that which was planted out from the bed, which will be ready before that grown in the ordinary way. The principal portion of the plants from the same sowing should be pricked out 3 in. asunder in a frame, in which put 6 in. of good soil on a firm bottom composed of ashes well rammed, into which the roots will not penetrate far. For this purpose the soil should be of a light sandy nature, to enable the plants, when moved for permanent planting, to be taken up with little breakage of the roots. Where Celery is desired late, say until April the following spring, a little seed should now be sown, as this will stand longer without running to seed than the earliest sowing.

GLASSHOUSES AND FRAMES.

Stephanotis as a Basket Plant.—Among the many plants used for conservatory baskets, the Stephanotis is seldom or never employed in that way. It has, however, occurred to me that it might be made one of the best of basket plants. It would, in the first place, be necessary to obtain plants of it with several good shoots rising from the bottom; these must be trained up stakes inserted in the pot, for the plants would perhaps be best grown in pots until they began to flower, when they could be set in the baskets. In order to ensure the plants flowering freely, the wood must be thoroughly ripened by being exposed to sun and air during the summer-time, either near the glass in a cool house, or trained on a south wall out-of-doors. The baskets in which they are to be placed should be prepared previously by having a pot, of the same size as that in which the Stephanotis is grown, placed in the centre. This should be packed round with lumpy peat and Sphagnum, and planted with Ferns and Lycopods, so as to hide the outside of the baskets. When all is ready, the empty pot can be replaced by the one in which the plant is growing. The branches of the Stephanotis might be arranged so as to droop equally all round the sides; and when in full bloom plants thus treated would have a striking effect in a moderately warm conservatory, where they would last in beauty for a long time. I have never seen the Stephanotis tried in this way, but I see no reason why it should not succeed.—S.

Stokesia cyanea.—This plant furnishes the chief supply of blue flowers brought to Covent Garden in a cut state in autumn. They first make their appearance early in September, and may be constantly seen in the florists' shops until late in December. Those who desire a really good autumn-blooming plant would do well to grow this. The blue Aster-like flowers are very large and showy, and are borne on the end of every branchlet, each bloom being about 3½ in. in diameter, and apparently semi-double. In its late-blooming property consists its chief value; for late-flowering, hardy, really good plants are scarce. It succeeds best in a well-drained, warm, sandy soil; but any garden mould will suit it if well drained and in a sunny situation. It is also very useful for conservatory decoration in autumn and winter. It may be readily increased by division in spring. The slips, after being taken off, should be inserted in a warm border or frame, a few inches apart, in sharp sandy soil. As soon as they get well rooted and begin to grow afresh, they should be transplanted, mixing a little river sand and leaf-mould with the soil. In August some of the plants may be lifted and potted, and placed in a frame, greenhouse, or window. If, however, large specimens be required, the plants should be potted earlier and shifted on as they require it, in order to obtain large plants before flowers are produced.—S.

Bouvardias Planted Out.—By planting out Bouvardias during summer in good rich garden soil, and keeping them well supplied with weak liquid manure, much better plants can be obtained for winter blooming than by growing them in pots. We lately saw a large house full of plants which had been thus treated, and which will make a fine display. They were struck in February, planted out in June for the summer's growth, and potted up during the first week in September; they were then placed in a cold frame for a few weeks until re-established, when they were removed to a lean-to house, where a little heat can be given them to assist in opening their flowers. All the varieties may be treated in this way with the best results.

Abutilons as Pillar and Roof Plants.—The gracefully-drooping, bell-shaped flowers of these are only seen to advantage when grown as pillar or roof plants, a purpose for which some of the more free pendulous kinds are specially adapted, as depending above-head, or weeping down from pillars, they have a very graceful effect. Many years ago I remember the old A. striatum trained along the roof of a conservatory, where it was always much admired and was seldom out of bloom, and now that there are so many hybrids of such improved character, there ought to be a few at least among them fitted for such a work. A. Boule de Neige is unfortunately a little too stiff, but is admirably suited for a trellis or walls, where associated with Lapageria rosea, or anything of that character possessing colour, the contrast with its pure white flowers is very effective and pleasing. When grown in this way it requires annual pruning in, so as to get plenty of fresh young breastwood, on which the blooms are formed; but the thing first of all is to get it to fill its allotted space, by encouraging the leading shoots to reach the sides of the trellis before being stopped, when by nipping out the buds they soon break and furnish the bare parts below. A. vexillarium is one of the best with which I am acquainted for training up under a girder or roof, where if the house it is in happens to be kept a little warm, it will flower the whole year through. To encourage it and others to do this they must have plenty of root room and good rich soil, and the assistance of manure water whenever they get dry at the roots.—S. D.

Clematis indivisa lobata.—This attractive greenhouse climber is just now nicely in flower in a cool house. The flowers are white and fragrant, but the stamens and pistils are off a purplish-red colour, affording a pretty contrast to the white petals. It is an easily cultivated plant in a perfectly cool and airy greenhouse. Where it is restricted to limited space it is best grown in a pot, for it is a vigorous grower, and soon covers a large space. The flowers are produced in profusion from the axils of the leaves, and this must be taken into account in training the plant. One matured shoot, well exposed to the light, will produce quite a wreath of flowers. It may also be trained in the form of a balloon if confined to a 9-in. or 10-in. pot. One or two limbs only should be led away from the root and trained regularly round the balloon trellis spiral fashion, so as to cover all the space, but without crowding the shoots in any way. About this season they will break freely and produce a mass of blossom. Common loam principally, with a little leaf-mould or peat and sand, makes a good compost in which to grow it.—W.

Large v. Small Plants of the Amazon Lily.—The flowers of Eucharis amazonica are such general favourites that whatever course of culture yields the best results is the one that should be followed. I have hitherto thought it best to grow good single bulbs in small pots, and by resting or partly drying off batches of plants in succession, I have had a constant supply of fine blooms; but where large numbers of flowers for cutting is the object in view, I think that large pots filled with bulbs will, as a rule, yield the best results, and if required for decorative purposes, there are few plants that combine the good qualities of a flowering and fine-foliaged plant so well as this Eucharis. We have at the present time several large specimens of it coming into flower, each furnished with, on an average, twenty spikes of bloom. They were in full blossom in November last, and were kept quite cool until near Christmas, in order to preserve their flowers, which we used in large quantities for table decoration. Since that time they have been subjected to ordinary warm greenhouse temperature. Being starved from want of pot room, we have supplied them with an unlimited quantity of tepid liquid manure, which few plants like better than the Eucharis. Many of the old flower stalks have not yet decayed, but I find that fresh ones are shooting up vigorously beside them.—J. L. M.

Spiræa palmata.—Exquisitely beautiful as this fine herbaceous plant is in beds and borders, it is even more so forced; but to have the flowers well coloured they must not be allowed to expand in heat; the plants should be set in a light cool house, where they can enjoy a moderate amount of air and receive plenty of water. So moisture-loving are they that they do best standing in shallow pans to intercept the drainage that runs through, which they soon reabsorb, and thus keep fresh without the attention they otherwise require to preserve them from flagging. I find that plants grown out in the open, and dug up in the autumn, are far preferable to any grown in pots, as the latter are never half so strong, and consequently do not bear such fine panicles of flowers. The best way to cultivate for forcing is to plant in very shallow trenches in a half-shady situation, as then they can be easily flooded with water occasionally, which is a great help in warding off red spider, so fatal to the foliage if they are allowed to become dry at the roots. This Spiræa admits of very ready increase by division, made any time before the plants have started much into growth, after which they should not be interfered with, as cutting through them then checks them severely, and is likely to end in their total loss.—S. D.

DOULBE PETUNIAS.

THERE is still time to sow seeds of these excellent greenhouse plants if a little heat can be afforded them. Double Petunias may be propagated by means of cuttings, but seedlings are preferable, as they grow stronger and give little trouble; but when any of very superior merit show themselves, it is always worth while keeping a stock plant of such for cuttings, which, put in now, soon strike root on a manure bed under a bell-glass kept close for a time. The single forms make grand beds if planted where they can have plenty of room to spread, but, as they are naturally strong growers, a poor soil is best for them, if deep, so that the roots can get well down; that checks any tendency to over-robustness, and yet affords the necessary support during dry weather. Besides forming magnificent beds, single Petunias make fine masses in borders, but when used in that way they require support; the neatest and best way of effecting this is using coarse-meshed rabbit wire, cut into yard lengths, which, run round and tied to a stake at the ends, forms a capital frame, through which they thread their shoots and completely hide the wire with their gay blossoms and foliage. Their are many other plants of a similar character for which a trellis made in this way answers well, and as they last for years, nothing for the purpose can be cheaper or handier. As Petunia seeds are very small, they should only be covered at the time of sowing, otherwise the young plants are unable to push through the soil. Pans for such seeds should be filled nearly full with rough leaf-mould, and on the top of that should be put 1 in. or so of finely-sifted soil, made perfectly level and smooth. That done, the next thing is to give a gentle watering, and then they should not be disturbed for a few hours, when all will be ready for sowing. This should be done thinly, and a little silver-sand sprinkled over the seeds, when, if placed in a moist heat, they will soon germinate, especially if the pan be covered with a sheet of glass or kept dark by a piece of paper for two or three days, as by that means evaporation is intercepted and a more uniform warmth maintained.
S.

Wistaria and Ivy on Railings.—The engraving on the next page shows a graceful mode of growing Wistaria and Ivy on railings which may be easily carried out by those wishing to form ornamental screens on railings, &c. The effect of the Ivy below is, of course, good at all seasons, particularly in winter and spring, when the Wistaria is bare. In spring and early summer the shoots of the Wistaria are liberally graced with large bunches of bloom, and frequently there is a second crop in autumn. The long shoots of the Wistaria require to be pruned in slightly in winter, and thus a kind of graceful and natural coping is formed to the Ivy-clad railing. Walls might be embellished in a similar manner. Forming graceful and enduring, though changeful, little pictures of this sort is that which best repays for expenditure in gardens.

ANSWERS TO QUERIES.

1876.—**Plants for a Small Greenhouse.**—It is better to grow a few plants well than have a larger number of leggy, indifferent specimens. Hard-wooded plants—Acacia armata, A. floribunda, A. Drummondi, Adenandra fragrans, Chorozema cordata splendens, Coronilla glauca variegata, Cytisus racemosus elegans, Daphne indica alba, Dracæna indivisa, D. rubra, Eriostimon buxifolius, Grevillea robusta, Habrothamnus fascicularis, Nerium rubrum plenum, double-flowered Myrtle, Pimelia Hendersoni, and Polygala dalmaisiana. A few Camellias, Azaleas, and Epacrises may be added, but do not start with too many, and in making the list I have had this especially in view. One or two of the soft-wooded Heaths also, such as Wilmoreana, are easily managed. The following soft-wooded plants are very desirable to possess:—Pelargoniums of different kinds (including the zonal section), Fuchsias, tuberous Begonias, and Tree Carnations. Cinerarias, Calceolarias, Cyclamens, Balsams, and Celosias are easily raised from seeds sown in spring; the two former, as well as Primula sinensis, can be grown best in a cold frame in summer, in rather a shady position. Eupatorium odoratum should be grown for winter flowering; it may be planted out in May, and lifted and potted in September. One or two of the greenhouse Palms might be added, such as Corypha australis, Phœnix dactylifera, Seaforthia elegans, and Areca Baueri. When they become too large they might be exchanged for small plants. Greenhouse climbers—Acacia Riceana, Clematis indivisa, Lapageria rosea, Tacsonia insignis, Swainsonia Galegæfolia, and Tropæolum Fireball.—E. H.

1875.—**Keeping a Window Gay.**—I have had hardy Primroses beautiful all winter. They should be divided now, planted out in shady borders, and potted again in autumn. Zonal Geraniums, again, should be another leading feature, and Fuchsias, Harrison's Musk, and Begonia Wiltoniensis. Calceolarias will do in the frame all summer. Annuals sown in autumn, potted up, and placed in the frame till the flower-buds are formed, then brought forward into the window, will flower early. Sow Myosotis dissitiflora in July; Saponaria calabrica, Nemophilla insignis, and Limnanthus Douglasi in August. Mignonette outside the window in a box is sweet and beautiful, as are also Wallflowers in spring and Ten-week Stocks in summer. A few plants suspended in baskets are a great addition to a window. Ivy-leaf Geraniums, Sedum carneum varigætum, Saxifraga sarmentosa, Creeping Jenny, and several Campanulas are suitable for baskets. For winter, when flowers are scarce, a nicely grown Laurestine would be useful, and one or two berry-bearing plants of Aucubas. Several others of the Japanese shrubs might be useful to give colour in winter, especially the variegated forms of Euonymus. If the window was large enough, a Palm or two of the hardy kinds such as Chamærops excelsa would give character of a striking kind; and the India-rubber plant, Ficus elastica, thrives well in a room. And then, to revert to flowering plants again, there is the whole family of bulbs, many of which must be grown, and scarcely any of them can come amiss.—E.

1899.—**Plants for Lancashire.**—For the situation named deciduous shrubs should preponderate, and it would be an advantage if a belt or even a row of trees that will stand the fumes and gases be planted on the side from whence they come. I have seen Lime trees used for such a purpose, formed into a dense screen by pruning, which topped and lifted over, so to speak, the bad atmospheric currents. When a break is thus established many things will grow under or just inside its shelter that could not otherwise be cultivated. From deciduous shrubs select Lilacs, Ribes, or flowering Currants, Laburnums, Thorns, common Berberry, Elder, scarlet berried, &c., Forsythia viridissima, Honeysuckles, Pyrus japonica, Syringas, Tamarisks, &c. Among evergreens, Aucubas, Berberries, Box, Cotoneasters, Ivies, of various kinds, evergreen Oaks, Japanese Privets, Rosemary, Yuccas, &c., may be planted. In situations where the fumes are excessive the common Elder may be used as a screen, as it seems insensible to their effects. All the Californian annuals may be sown now in the open with a fair prospect of their doing well. The following list may help to guide in selecting proper kinds:—Nemophilas, Lupinus, Sweet Peas, Saponarias, Stocks (ten-week), Asters, Victoria and other Nasturtiums, Tom Thumb, Stock Virginian, Sweet Alyssum, Candytufts, Clarkias, Collinsias, Eschscholtzias, Larkspurs, Limnanthus Douglasi. Sweet Williams, Antirrhinums, Wallflowers, and Forget-me-nots may also be soon for next year's flowering, as may also spotted Foxgloves, and many other things that want of space prevents me alluding to now.—H.

Double hybrid Petunia.

1832.—**Glazing without Putty.**—My position is very similar to that of "E. N.," and I was about to ask your correspondents who have adequate experience to state their opinions on the points mentioned by him. I have recently seen a cool greenhouse with the sash-bars running horizontally from end to end, and not, as usual, from back to front of the house. The glass used is about 1 ft. in width, and much longer; each piece appeared to be inserted in a groove at the top and secured at the bottom by a small iron button revolving on a screw. My inspection was a chance one, and too hurried to

enable me to give an adequate description. The gardener quickly removed a pane or two, and as easily replaced them. I observed that in some instances there was a small space between the respective panes; but I was assured that no wet ever penetrated, and that there was no damp or drip; further, that not a plant was injured by frost or cold during the past severe winter. The advantages claimed for this sort of house were simplicity and great economy as to cost, with handiness for removal if required. The appearance was not only novel, but very pleasing; and for lightsomeness I have never seen anything to equal it. Every plant looked very healthy, although the heat was supplied by an oil-stove.—B. W.

—— The system described must be the same as that known as "Hellewell's Patent." Having seen and minutely inspected a house constructed upon this system, I can answer for its utility. Its chief recommendation is that it avoids all necessity of outside painting. The glass can be taken off easily, cleaned, and then replaced, in a very short time. The technical particulars are as follows:—Rafters, according to length of house, about 6 ft. apart; on these are laid purlines according to length of glass squares, say 21 in. The glass squares are laid on the purlines just as slates are, and kept in their places by clips (Hellewell's Patent). I am so satisfied with its simplicity that I am now constructing a plant house on this system, and shall not revert to the old system of rabbets and putty, and when my present houses require new woodwork, shall adopt the modern system.—Arundo.

1897.—**Cucumbers on a Landing.**—If thoroughly well cared for, Cucumbers may be grown in the situation named. I should recommend Sion House, Munro's Duke of Edinburgh, or one of the short-fruited vigorous kinds. The shoots must be trained on wires, or strong string strained tightly will do. About 14-in. pots will suffice; and the soil must be turfy loam and old manure—about one-third of the latter; and it should be used in a rough condition, that is, simply broken up with a spade. Do not begin too soon; the first or second week in May will be early enough. Plant strong vigorous plants that have experienced no check, and have not been raised in a very hot place.—E. H.

1874.—**Cesspools in Gardens.**—In summer such crops as Cauliflowers, Cabbages, Peas, Onions, Scarlet Runners, old Asparagus beds, Gooseberry, Black Currant, and Raspberry quarters will imbibe a good deal of sewage. Strawberry beds may have a supply from this time till the fruit begins to colour; and in winter, or when it cannot be profitably used elsewhere, pour it over the roots of fruit trees in orchards, &c. Cut Grass may be usefully employed for mulching over the roots of plants and fruit trees; it may be dug or trenched in the land at once, as cut, or be mixed with earth to absorb the unpleasant smelling gases evolved by fermentation.—E.

1929.—**Lilium auratum Out-of-doors.**—Lilium auratum should be planted in a shady place, not under the drip of trees, in any good soil that can be kept tolerably moist. Ours are grown in a good but rather heavy loam in the Fernery, where for the last two years we have had them and other Lilies flower beautifully. They are all coming up quite strong this spring, in spite of last winter's frost, which killed Laurels and Aucubas down to the ground. The bulbs are left in the ground all the winter, protected from slugs by a good dusting of soot in the spring, and well watered all the summer. On this simple treatment all Lilies seem to grow handsomer each year. I may mention the fact of one bulb of Lilium auratum remaining dormant a whole year in an undisturbed spot among the Ferns. Planted one spring it did not grow till the next, when it sent up three shoots, one of which was strong enough to bear three large flowers.—Lover of Lilies.

1838.—**Blooms Falling off Roses.**—Maréchal Niel rose often produces more buds than come to perfect flowers. In what condition are the main stems; are there any symptoms of canker? A little artificial stimulant, such as Standen's or Clay's, will be useful. The falling of the buds arises, no doubt, from exhaustion or lack of power in some form.—E. H.

1911.—**Bulbs the Second Year.**—I have planted Hyacinths for many years in the same mixture, viz., one-third leaf-mould, one-third well-rotted manure, one-third sand; they have been planted in November and lifted and dried in May. Not only have they continued to bloom beautifully year after year, but their offsets, treated in the same manner, have made good bedding bulbs. These two last winters, however, have settled them; they are nearly all gone, and, after many years of faithful service, must be replaced.—S. F. M. L.

1885.—**The May Flower** (Epigea repens).—This may be obtained at Mr. Ware's nursery, Tottenham; or Messrs. Backhouse and Sons', York.]

1893.—**Management of Fern Case.**—Keep the plants free from all dead fronds and decaying matter generally; wash the glass when necessary to keep it clean and bright. Plants growing in a tight-fitting glass will not require much water, as the evaporation condenses on the glass and runs down to the roots again. But for most kinds of Ferns a little ventilation sometimes is beneficial by tilting up the glass or otherwise for an hour in the morning.—E. H.

1894.—**Cyclamens and Cacti after Bloomng.**—Put your Cyclamens in a cold frame, and Cacti on a sunny shelf in greenhouse. Give little water.—G. B., *Bury*.

1877.—**Growing Gardenias.**—Gardenias grow best in a moist stove, syringing them several times during the day; they require very little shading. I have grown them well in top sod roughly chopped up, mixed with bones, sand, and a little dry cow manure. They are fond of liquid made from cow manure when growing freely.—J. H.

1832.—**Glazing Without Putty.**—In answer to "E. N.," I write to say that last autumn I put up a greenhouse on the same principle as he suggests, and find it answer exceedingly well It is perfectly watertight, &c., and, having had others built the other way, I consider it equally as good as the old style. The house is in rather an exposed position, but it has sustained no damage. I may say that there is a nurseryman close by who builds all his houses on the same principle, and from whom I copied.—H. S. H.

Wistaria and Ivy on Railings

1751.—**Peas and Mice.**—I recommend the following as a remedy against mice among Peas:—Take some Furze and chop into lengths of 1½ in., 1 in., and ½ in., then put some on top of the Peas, and then the earth and some more Furze on the top. This is a sure preventive against mice and worms, and even against birds.—A. H. C. W.

1905.—**Hybridising Daffodils.**—I think hybridising Daffodils is a great mistake. I am of opinion that the most important matter is to keep the species or distinct types true, rather than run them into a lot of varieties.—H. H.

1936.—**Planting Potatoes.**—In the hints for Potato planting it is stated the sets should only have two shoots. Does it mean that that the others should be pulled off, or, that the Potatoes should be cut into pieces, each piece with two shoots?—A Novice. [All the shoots but two should be cut out with the point of a knife.]

1937.—**Ferns Under Glass Case.**—I have an earthenware Fern case, with bell-glass top, and Ferns supplied from greenhouse. Lately, the new fronds of the Fern die off. I keep the case on a sideboard in a rather large room; I do not lift the glass up nor water it much. Would the gas or the fire affect it?—R. H. [The bell-glass should be lifted for an hour daily when the gas is not burning. Wipe the glass and water the plants.]

1938.—**Potting Plants.**—I find in Gardening that young plants are to be shifted into larger pots as the pots fill with roots, but how can I ascertain when the pots are full of roots?—A Novice. [Place your left hand over the top of the pot, letting the plant come between the middle fingers. Then turn the pot upside down, and gently tap the edge of the pot on a table or bench. Lift up the pot with the right hand, and you will then be able to see the roots. Put the plant in the pot again, and give it a few sharp raps on the table to fit the ball of roots into its place again.]

1939.—**Pruning Fruit Trees.**—I have several young Peach and Pear trees which have never been pruned. How far back had I better prune them? They are beginning to show leaf. I had them last year from the nursery.—Hampstead. [It is rather late to prune them now; your best way would be to rub off the leaf-shoots of the parts that should be cut off, and when the young growths have got a good start these bare pieces might be removed. We cannot advise you how far to prune them back without knowing what they are like now, and in what form you would like to train them. Ask some good gardener to see them.]

1940.—**Plants in Vineries.**—My Vinery was used as a stove from 1874 to March 1879. Will this account for small crop last year, and bad promise this, or is it bad pruning? [If a stove temperature was kept up during the autumn and winter months there is no wonder that the Grapes were poor. This year let the Vines carry as light a crop as possible, and keep the temperature of the house rather low, say not to exceed 60° by night except in very warm weather. Give abundance of air daily, and leave a little on all night. Keep the shoots thin, and do not stop them too close; let every leaf be fully exposed to the light. When the leaves begin to fall in autumn, throw open the house till sharp weather sets in; then prune the Vines and let them break into growth naturally, that is, without forcing. By these means you may reerruit their strength.]

1941.—**Fly on Apple Trees.**—What can I do to my Apple trees, which are just ready to burst into blossom? Every bud is covered with green blight.—J. Plater. [Take 4 oz. of Quassia chips, which may be got at the chemist's, and boil them for ten minutes in a gallon of soft water. Strain off the chips, and add 4 oz. of soft soap, which should be dissolved in the water as it cools. When nearly cold, syringe the trees with the liquid; ten minutes afterwards syringe it off with clean soft water Repeat the operation when necessary.]

1942.—**Fruit Trees in Greenhouse.**—I have in my greenhouse some Cherry and Peach trees a few inches high, grown in pots from the stones, planted some four months back. How should they now be treated to ensure strong and vigorous growth?—Brockelsby. [Plant them out-of-doors under a south wall in good soil, taking care, however, to harden them off a little at first.]

1943.—**Forcing Lilac.**—In Gardening for April 3 there is a paragraph "How to force Lilac." What time ought the bushes to be taken up?—Sydenham. [When the leaves have fallen. If a succession is needed, a few—at intervals of three or four weeks—should be put in heat.]

1944.—**Box for Plants.**—Which is the best kind of box for sending cut flowers by post?—J. Brodie. [A tin box is the best for plants. Wadding, not wool, should be used, as the latter absorbs the moisture from the plants. Ivy or Spinach leaves answer well for packing when there is a scarcity of damp Moss.]

1945.—**Lilium auratum.**—Is it too late to put in bulbs of Lilium auratum? if not, where can I get them? and the price of them?—C. H. W. [Procure some bulbs at once and pot them in equal parts sandy loam and rotten cow manure or leaf-mould. They may be obtained from any good bulb and seed house. The price varies according to the size of the bulbs; fair-sized flowering bulbs may be had for about 1s. each.]

1946.—**Aspect for Spring Garden.**—Would a border under a west wall be well suited for a spring garden?—J. L. [Yes.]

1947.—**Sizes of Flower Pots.**—What is the proper measurement of the different sized flower pots, commencing with the smallest one?—W. J. L. [Thimbles, 2 in.; thumbs, 2½ in.; sixties, 3 in.; fifty-fours, 4 in.; forty-eights, 5 in; thirty-twos, 6 in.; twenty-fours, 8 in.; sixteens, 9½ in.; twelves, 11½ in.; eights, 12 in.; sixes, 13 in.; fours, 15 in.; twos, 18 in.]

1948.—**Bulbs after Flowering.**—I have a few pots of Hyacinths, Tulips, Crocuses, &c., which are now dying down. Will it be best to take them out of the pots and dry them and store them away, or leave them in the pots and gradually withhold water until quite dry? The usual plan is to plant them out in the garden in rich soil; but, unfortunately, I have no garden only in pots. If left in pots, what is the best way to start them into growth again?—A Learner. [Keep the soil in the pots moist until the tops have died down. In autumn re-pot them and place them out-of-doors plunged in ashes, and let them come on gradually. They will be of very little use, we are afraid.]

1949.—**Propagating Palms and Genistas.**—How are Palms and Genistas propagated, and at what time?—J. V. [Palms are propagated from seeds sown at any time in a warm temperature; Genistas from cuttings, in September, placed in a frame or greenhouse.]

1950.—**Tea Leaves as Manure.**—Are Tea leaves any use for the manuring or improving soils? Are coffee grouts of any use for the same purpose?—H. C. F. [The benefits derived by soil from Tea leaves would be very small unless you had a large quantity which had lain long enough to get decomposed. Coffee grouts will do neither good nor harm.]

Scale on Apple and Plum Trees.—*J. Hiam.*—The scale on the Apple tree is apparently what is called the mussel scale. The best remedy we know of is seal oil, well rubbed into every crevice of the bark when the leaves of the tree fall off in autumn. That on the Plum tree is the common brown scale, which may be cured in the same way as the other.]

Shading Greenhouses.—*H. F. J.*—Thin canvas on rollers is the best; but if you would rather paint the glass use whiting and sour milk, mixed to the consistency of paint; or, nurserymen sell some material called "summer cloud," which is very good for the purpose.

Cape Gooseberry.—*K.*—The botanical name of this fruit is Physalis edulis, belonging to the order Solanaceæ. A native of South America.

A. F.—Kindly ask your questions on separate pieces of paper.

Large Forget-me-not.—*S. F. M. L.*—You probably mean Omphalodes verna.

H. P.—You will get all the information you ask in our advertisement columns.

J. H.—Your communication can only be inserted as an advertisement, in the columns set apart for that purpose.

QUERIES.

1952.—**Slugs in Greenhouses.**—Can any one tell me the best course to get rid of slugs in a greenhouse? I have some herbaceous Calceolarias which are being spoilt by them.—SUBSCRIBER.

1953.—**Azaleas Growing too Soon.**—Can any one tell me how to prevent the new wood of Azaleas starting before the flowers are out? Does it injure the plants to nip out the new growth?—SUB.

1954.—**Constructing a Fernery.**—I have a greenhouse which I wish to convert into a Fernery. It is in a shady situation. The north, west, and south sides are of brick, and the east side glass, with glass roof and well-drained cement floor. It is about 7 ft. square. Would some one give me a few hints as to the best way of covering the walls with virgin cork, &c., so as to make it into a little glen, with fountain, &c.?—T. W. W.

1955.—**Rats in Country Houses.**—Is there any way of ridding houses of these unwelcome guests? Poison only makes one evil to counteract another, and is besides dangerous where children and domestic animals are found, and trapping is a slow process where such rapid multiplication takes place.—NORTHUMBRIAN.

1956.—**Vines.**—I would be glad if "J. G. K." would give a few more remarks on the the long rod system of Vines when started, and what fire heat is to be kept up, will 70° or 90° do? I have a Vine grown on the spur system, which has borne well, but this year it has not been pruned. The shoots are now 2 ft. long, without a sign of fruit. What shall I do? Will they bear this year? There is now no fire kept up; the shoots are not weak; the solar heat about 70°. There are three shoots to each top joint; ought they remain, or leave only the leader?—G. B. M.

1957.—**Treatment of Hoya carnosa.**—I have some cuttings of Hoya carnosa just started in 3-in. pots in a temperature about 60°. Can I flower them this season? and what treatment should they receive?—W. C. REID.

1958.—**Treatment of Vallottas.**—I have some small bulbs of Vallottas, offsets from larger bulbs. How ought they to be treated? and how long will they be coming to a flowering size?—J. W. L.

1959.—**Perennials for Sowing in July.**—Will some one kindly give me the names of a few hardy or half-hardy perennials of compact growth, similar to the dwarf Antirrhinum or Pentstemon, that I can sow in July or August to blossom the following summer from July to October or November?—J. S. M.

1960.—**Culture of Sunflowers.**—Will any one inform me as to the best method of sowing and raising Sunflowers, and any hints that may be useful in their cultivation?—JOHN HENRY.

1961.—**Mixed Houses of Plants.**—Is a temperature of 50° suitable for all the following plants, viz.—Amaryllis, Bouvardias, Begonias, Camellias, Chrysanthemums (winter flowering), Cyclamens, Fuchsias, Geraniums, Heaths, Hyacinths (and other bulbs), Liliums, Lobelias, Orchids (winter flowering), Primulas, Passion-flowers, Roses (Maréchal Niel), and Violas? Would they succeed if grown together?—J. J. M.

1962.—**To make a Garden Pay.**—Is it possible to make a small garden yield a profit? Having about a third of an acre, I grow all the fruit and vegetable consumed by the family, purchasing them at the prices at which they are retailed by the shopkeepers; but I always find that, although I work hard in the garden, after paying for seeds, manure, and a man's occasional labour in digging and trenching, I save very little, and might as well buy at the shops and save myself much fatigue and care. Some of my friends say that a man who recently possessed a large income, extensive grounds, &c., is not the person to make a small garden pay; but I think otherwise, as I not only possess a practical knowledge of gardening, but also work like a day labourer to make my little plot of ground yield me a fair return. The result is, however, very unsatisfactory, and I shall be glad if some practical gardener will help me as to the best method of turning my knowledge to account.—ANXIOUS TO KNOW.

1963.—**House Slops as Liquid Manure.**—Will some reader inform me how I can utilise the refuse house liquids? If I apply them as produced they act too vigorously and do more harm than good; and yet if I allow them to stand in a tub sunk in the earth they smell most offensively, and are, I imagine, unwholesome.—VECTIS.

1964.—**Making a Lawn.**—I have a piece of ground at the back of my house 50 ft. long by 15 ft. wide, which I wish to make into a lawn. I believe the quality of the soil is good, but rather stony. I have had the whole of it dug up and thoroughly loosened, and I should be glad to be informed how I am to proceed. I have no turf available, so must therefore use Grass seeds.—ALPHA.

1965.—**Single White Camellias.**—Can any one tell me where I can procure a plant of the single white Camellia—called, I believe, Camellia japonica? I presume it requires the same treatment as the other kinds.—K.

1966.—**Sowing Seeds of Conifers.**—I have some seeds of Pinus Normanniana, Lambertiana, and other Pines, which ripened this year in Kerry particularly well. Would some one tell me how they are to be sown, and where?—MAJOR H.

1967.—**Book on Horticultural Chemistry.**—I have come into possession of a garden this year, and not having devoted any time to the study of this subject, I will be much obliged if any one will recommend me to a cheap work which treats the subject from a chemical point of view—by this I mean a book that not only gives directions, but states the reason why, as far as practicable.—REASON WHY.

1968.—**Crown Imperials from Seed.**—Last autumn I sowed seeds of the Crown Imperial Lily, and three plants have come up. What is the proper way to treat them? Am I to leave them in the box they were sown in? How long will it be before they flower?—J. M. M.

1969.—**Painting Greenhouse Floors.**—The tiled floor of my greenhouse is so difficult to keep clean. I intend painting the tiles red and black; will this succeed? Or, can any reader suggest a better plan?—TERRA COTTA.

1970.—**Grubs on Lawns.**—Can anyone advise me how to get rid of a small lead-coloured grub which has appeared in numbers during the last few days, crawling from the Grass plot on to the gravel walks? I do not know its name.—J. M. G.

1971.—**Pruning Jasmines and Berberis.**—I have some of these plants with long bare branches; how should they be treated?—EARNEST GARDENER.

1972.—**Flower-pot Stoves.**—Would "H. M. D. B." kindly give me plainer instructions respecting the kind of stove? I cannot quite understand how the fire is to burn without air. Does the tin pan rest quite on the inner pot? Can the size of the fire-clay pots be given, and where could I obtain them?—INQUIRER.

1973.—**Soot in Gardens.**—If a bucketful of soot is buried in the garden, how soon can that particular spot be used for planting in?—IDAWARRA.

1974.—**Soot-water for Plants.**—Is there any means of overcoming the buoyancy of soot, so that it may be mixed with water, as frequently recommended in gardening publications?—IDAWARRA.

1975.—**Parsley for Exhibition.**—Will any one tell me how to grow a good potful of Parsley for exhibition in July next? I have some plants about 1 in. high in a cold frame.—JOHN BROWN.

1976.—**Climbing Roses not Flowering.**—I have a Maréchal Neil Rose tree in my greenhouse which makes plenty of very nice foliage, but I do not see any sign of flower buds; the plant is 8 ft. long. I have also a Gloire de Dijon Rose quite as large, which is in bloom; but the foliage is very brown, the leaves go almost yellow, and some have very dark-brown spots upon them and others drop off. What is the cause and remedy in both cases?—ANXIOUS INQUIRER.

1977.—**Peat Charcoal.**—Will "Rustic" (see p. 41) say if this is an article of commerce sold in London or Birmingham, or how is it procurable?—J. T.

1978.—**Iris chinensis.**—I have some plants of the above which were brought from Genoa four years ago. They were taken up when in flower, and have never blossomed since; they are immensely strong and large. I have had some in the open ground and some in a cool house. What treatment should I adopt? In the garden near Genoa where I saw them covering the ground like Bluebells they were, I think, rather shaded. Would a roasting such as suits Guernsey Lilies be likely to suit?—J. L.

1979.—**Calochortus flavus.**—I have some seed of this, and shall be glad of information as to growing it.—C. D.

1980.—**Newly-made Lawns.**—I have lately had some turf laid down in my small garden, which turns out to be meadow turf, full of Buttercups. I cannot afford to relay it, and am doing my best to eradicate these pests with a spud. I propose also to roll frequently with a heavy roller, having observed that in the footway through a meadow one rarely sees a Buttercup, however full of them the meadow may be. I presume, therefore, that pressure is hurtful to them. What else can I do?—A NEW SUBSCRIBER.

1981.—**Wild Flowers.**—Can your readers inform me where in the neighbourhood of London (especially the south side) I can procure wild flowers—notably Wood Anemone, Wood Sorrel, and Hyacinth—and also if these come into bloom in the month of March or April in that locality?—M. M. S.

1982.—**Treatment of Cactus.**—I should be glad of some hints on the management of the Cactus. I have a large one which looks dry and shrivelled, but I do not think it is dead. What can I do to revive it?—A SUBSCRIBER.

1983.—**Creepers for North and East Aspects.**—Can any one recommend me a few good creepers for north-east and due north aspects?—S. F. M. L.

1984.—**Unhealthy Pear Leaves.**—I have some Pear trees the leaves of which are not so healthy as could be wished; they have been the same for two years. They are red and spotted, black spots appearing as the season advances. The roots were pruned this winter pretty closely. Can any one suggest the cause and remedy? They have borne no fruit for some years.—J. M.

1985.—**Glass for Conservatory.**—I am now erecting a conservatory, and my architects wish to put plate glass in the front sashes. I have been told plate glass is not good for plant growing. I should like to have any reader's experience.—FREDK. BRIDGFORD.

1986.—**Watercresses.**—I read that Watercresses are very successfully grown at Gravesend and Waltham Abbey. How are they managed? And how are they managed in other places where they grow so luxuriantly and beautifully, and are so robust and tender? Could they be well managed in the overflow water from a well, and, if so, how should the bed be formed, and the plantation worked? And could a person grow a few for home use in a cottage garden by artificial means, and, if so, by what means?—T. J. S.

Mice and Peas.—I saw about three weeks since a query from a correspondent in GARDENING as to how he should protect his Peas from the ravages of mice and birds. The day after I sowed my first Earlies I was astonished to find that great destruction had been done during the night by mice. I at once made a thick covering of soot down the whole length of the trench, and slightly patted it down with the spade to prevent the wind from blowing it away. From that time I saw no more traces of mice or birds, and I do not believe a single Pea has been stolen since. From the long exposure to wind and weather, it is quite harmless to the young plants when they appear above the soil. I have now a beautiful robust row of Peas, which I am sure are second to none in this neighbourhood.—G. GREEN.

POULTRY.

SITTING OF HENS.

There is a general notion that old hens make the best mothers; but as far as my experience goes, I have found quite the contrary to be the case. A pullet will sit and hatch as well, and make a far more devoted mother than an older hen. In sitting a hen it is best to remove her quite away from the others; and if, as some hens dislike sitting anywhere but where they have been laying, remove her in the evening, give her four or five china nest eggs, cover her up till the morning, then let her out and feed her; if when placed before the nest she will return, you may safely sit her in the evening. Most people give thirteen eggs, but you will find that you will generally get as many chickens out of eleven. I always make up a nest with a good sized turf at the bottom, place the hen in it and give her the eggs one by one, which she will take with many expressions of satisfaction. She will probably not come off the nest the following day.

When a hen leaves the nest, do not give her food directly, but first let her have a dust bath, as it is of great importance she should not get vermin on her; and you can easily give her food after she has returned to the nest, We always give our sitting hens a little chopped meat, and a drink of water at midday, and if the weather is warm they are very grateful for another drink in the evening. When the eggs are hatching it is best to remove all the chicks as soon as they are well nested, or the hen (especially if a pullet) will get up to look at them, and thus endanger the well-being of the others. Also remove all eggshells. If a chicken cannot get out after having pecked the shell, take it and remove bit by bit the top shell, and dribble down some warm water; by aid of this the chick, if returned to the nest, will be able to extricate itself, and you will save it. As a warning to young beginners I may say, Never set your hens on hay, or your chicks will be glued to the shell, and you will lose great part of them. The first hen we ever sat we made this mistake and lost several chicks. The day after the chickens are hatched they should be fed on hard-boiled eggs and cracked grits soaked. At the end of a week they may be fed on barley meal, oatmeal, and soft scraps. At the end of a fortnight give whole dry grits, but do not give grain till they are six weeks old, and then only sparingly. For holding water nothing is better than a cup inverted in a saucer. If your chickens are troubled with lice sprinkle them with Keating's insect powder, and give them a nest of lime rubbish. It is better for the first week to give the hen a separate dust bath away from the chickens; after that they will dust with her. My hens will, if you put your hand under them, at once rise and allow you to see that all is right; and one last year brought her four-days' old chickens into the kitchen and sat down with them by the fire.—AMATEUR ALECTRYOLOGIST.

Feeding Hens when Sitting.—Would some reader tell me whether hens sitting must have free access to water, or is wetted food enough? What is the best food for sitting hens? and does not too much water create looseness, as the hens seem to drink and go to the eggs again?—MABOR.

Disease in Fowls.—I have a lot of chickens, but have lost a large number from the following cause:—When the chickens are a few weeks old there forms on the hinder part of the body a cake or lump of hard dirt. I have washed many of them and some have lived, but I lose four or five a day. A neighbour tells me it is a kind of diarrhœa, but cannot inform me of any remedy.—RHODA.

Croup in Poultry.—The occurance of a dry horny scale upon the tongue is generally called "pip." The dry, scaly tongue is, however, only a symptom caused by some other disease, such as gapes, catarrh, or roup. If the scale or hardened membrane is loose, it should be removed. If "F. B." will give particulars of symptoms, whether there is any discharge from the nostrils, &c., I shall be glad to give further information.—C. W. A.

Fowls Losing their Feathers.—All the breast feathers of one of my light Brahma hens have come out, and she sits on the straw in the nest all day long and eats scarcely any food. What is the reason of the breast being bare at this time of the year? I shall be glad if anyone will tell me what is best to do.—A. J. A.

Fowls Eating their Eggs.—I have two Cochin hens sitting; they eat their eggs. What can be done to prevent this?—F. A.

Eggs for Hatching.—If the fowls are ten months old, their eggs should certainly be good for hatching; and considering only one hen to a cock, all eggs should be considered fertile.

Pale-yolked Eggs.—The paler the better; as a rule, they are a better flavour. Dark-yolked eggs mean, as a rule, that the fowls get very rank food.

—— Black Hamburghs require a good range of Grass land to roam upon, and if fed once or twice a week with scraps of meat, raw or under-cooked, the yolks of the eggs will be found to get darker and richer.—C. J. M.

Fowls Plucking each others' Feathers.—I should say you give your fowls too much fatty matter. This should be stopped for a time, and then only given in small quantities. Put some rusty nails, and occasionlly a pinch of Saffron, in their water. The feathers will not grow again till next moulting season.

Serious Loss of Fowls.—I feel sure that it was the lime that killed the fowls, though I do not quite agree with the feeding they had. Pollard, bran, and Potatoes mixed, and given just warm, are very good; but they should have Barley instead of Oats, and occasionally a little Wheat. Peas are also good for a change.—C. Harxurot.

Eggs for Hatching.—Will some one kindly explain the way to discover whether an egg is likely to produce a chicken or not?—H. B.

Loss of Fowls.—The disorder "N. S. Durrant" lost his fowls by prevailed here (East Kent) two years since. It seemed almost incurable, though pills of camphor and chalk, with a little brandy, sometimes saved the birds. It only appeared in the valley. Mine and other birds on the hills escaped; but it was most contagious, and seemed a kind of choleraic epidemic. Whitewash, lime sowing on the ground, and disinfection, is most desirable before re-stocking.—C. H.

HOME PETS.

HOW TO BREED CANARIES.

First we will spreak of the breeding cage. A good breeding cage for one pair of birds should have two rooms in it, with a hole cut in the partition for the birds to pass through; and then you want two slips, one wired and one not wired, so as to be able to shut off the birds from each other, as you may require; there ought also to be places for seed and water to each room. Now thoroughly clean out the cage and whitewash with new lime; cleanliness is of the greatest importance while breeding canaries. Next choose out the birds; one bird should be a yellow, and one of buff; it is of little consequence whether male or female be the yellow or the buff bird; still, for myself I prefer yellow cocks and buff hens. Now for the time to put the birds together. I believe the last week in February, or the first in March, to be quite soon enough; I do not care for young ones tell we get twelve hours' sun in a day. When the birds are paired, give regularly once a day grated eggs and bread till the hen lays her eggs; attending to this will prevent the hen being egg-bound. Of course you will have provided the birds with nesting material and nest box. Now as the hen lays her eggs take them out each morning till the fourth egg is laid, then place the three eggs back again in the nest; the reason for this is that most canaries begin to sit close as soon as the first egg is laid, the consequence being that the first laid egg is hatched three or four days before the last, and the oldest birds being the largest, crush the small ones or smother them to death. Canaries are seldom more than thirteen or fourteen days hatching their young ones if they sit properly. When hatched, supply the old birds three times a day with a small quantity of grated egg and bread.

When the young ones are about a fortnight old the hen bird will show signs of nesting the second time; so you must put a fresh nest-box in the other room, with fresh nesting material; do not forget this, as if nothing else is to be had the old birds will pluck the feathers off the young ones, which is not desirable. As the hen lays her eggs again, do with them as before; by the time she commences sitting the first young ones will be leaving the nest-box and hopping about the perches, perhaps getting into the other room and bothering the hen bird on her nest. To avoid this, take the wired slip and shut the cock bird in the other room with the young ones, supplying them with egg and bread; the hen does not require any egg while sitting. You must watch the birds after parting them, as sometimes the hen will refuse to sit with the cock parted from her; should this be the case let the cock back again, and use the wired slip, when he will feed through it.

By the time the hen hatches the second brood the first will be able to take care of thamselves, when they must be put in a separate cage and supplied with crushed hemp and canary seed, gradually decreasing the egg food, and stopping it as soon as they will live on seed alone. I do not advise giving young birds green food, but I believe it is good for the old ones while breeding. Groundsel, Chickweed, and Lettuce leaves are what I generally use. I also like to have a piece of mortar in the cage for the birds to peck, and the bottoms of the cage sanded over.

The above is my method of breeding canaries, and I have been pretty successful in it. I have made no mention of the various kinds or breeds of canaries, on which many important things might be written. I just give a list of them:—Norwich canaries, Lancashire coppies, Yorkshire, Belgian, Lizard, Scotch fancy, London fancy, Cinnamon. A. Locke.

BEES.

Plants for Bees and Starting Bee-keeping.—Bees will gather honey close to their hives or up to two or three miles distant. There is no necessity to plant close to the hives. Mignonette, Forget-me-not, Borage, also Cabbage, Turnip or Mustard flowers, are great favourites. Swarm of bees should be ready about first week in May; if sent off directly, *i.e.*, day after they have swarmed, they will travel well in the straw skep they were taken in, the bottom being covered with perforated zinc securely fastened. I strongly recommend wooden hives, placed facing south-east, with a path behind. The swarm would only want feeding if weather was wet just after their arrival. No implements required yet. Cannot even guess at the amount of honey likely to be made unless I know size of hive and style of country—perhaps 30 lb., perhaps 10 lb.—G. C.

—— Lose no time in procuring your stock; the sooner they are removed now the better. Have the hive tied closely up in a strong coarse cloth. The quantity of honey produced the first and following years will depend upon the season and the county; 20 lbs. a hive on an average is a fair harvest. The Stewarton hives are highly spoken of, so is the bar-framed hive. The best aspect is south-east. Bees will not require feeding now unless the weather turns cold or wet. It would not pay to take the honey from the stock, you would most probably lose the swarm; be content with supers. It is very little use planting flowers for bees.—A Subscriber.

—— The hive of bees ought to be obtained at once and placed facing south east. The best kind of hives are on the "hut" principal; two boxes (or three) placed side by side, with communication of half an inch cut out of side of boxes, and a hole of about 3 in. in diameter on the top of each box, for small round skeps to be put on. The quantity of honey to be obtained depends on the country round. If near a town or meadow land, only a small quantity must be expected, but if near Clover fields, Heath, Bean fields, and Lime trees, a much larger quantity; and this again will depend on the amount of sun during the season. Twenty or thirty pounds of honey may be obtained if the season is favourable; but on no account rob the bees of all their honey; they ought to have at least 20 lbs. of honey left for their share, if they are to do well. About May, or first week in June, there should be a swarm come from the hive of bees, so the box or skep must be ready to receive them, on whatever plan is chosen, and nine days after (weather permitting) a smaller flight; nine days after perhaps another, which may be put together in a smaller box or hive. The bees ought to be sent securely packed, with a piece of perforated zinc placed on the top or entrance for air and ventilation; the hive must not be placed near a wall. Probably the bees will require feeding till May, as in most neighbourhoods the bees collected but little honey all last year. Salvia nemorosa is a good plant for bees in the autumn.—A. F. B.

Sea Sand for Plants.—If laid aside exposed to the weather for nine or twelve months, sea sand answers well for striking such things as Geraniums in. We only use it for destroying misplaced vegetation.—M. D.

AQUARIA.

STOCKING AN AQUARIUM.

Having had a good deal of experience with aquaria, I think I can give "Millgate" the information he requires. As I do not know what kind of aquarium his is to be, I will assume that it is an inverted bell-glass, of, say, 18 in. in diameter. The first thing necessary is some small shingle, which may be procured at any of the fish-shops. It varies from 4d. to 6d. a quart; he will want about three or four quarts. This should be well washed, boiled in fact, in several waters to ensure its perfect cleanliness. This should be laid at the bottom of the aquarium. A few small pieces of charcoal at the bottom (hidden by the shingle) would be desirable. Do not place marine shells, however beautiful, in your aquarium; they are out of place. A little ornamental rockwork rising to the top of the water has an ornamental appearance. The next thing to be done is to place the aquatic plants in. The best and most beautiful, as well as most lasting for the purpose, is Vallisneria spiralis. It is expensive to begin with; the roots vary from 4d. to 1s. each; about 3s. worth would furnish an 18-in. glass well. Lilies are a mistake in an aquarium, as they are liable to decay, and poison the water. The Cape Pond weed, however, is an exception. It should be planted in a small flower-pot with shingle, and buried at the bottom of the aquarium. It blossoms freely. A few pieces of Frogbit floating on the surface are desirable. A piece or two of Anacharis may be added; nor should a spray of Myriophyllum spicatum be left out. The weeds should be planted well in the shingle with a little well-washed river sand—not silver sand, which will cloud the water. Clear cold water should now be gently poured in from a can with a fine rose. The aquarium should be filled not more than three-parts full. It should be left for two or three days. Before placing expensive gold fish in, half-a-dozen minnows should be turned in, and if they do well, when a week from the first starting of the aquarium has expired, the other fish may be safely added. If gold fish are to be kept, be content with small ones, and do not be tempted to purchase large fish, which will soon die. The following would be a good selection of fish:—Six gold or silver fish (various sizes), six minnows, two carp (small), two tench ditto, two eels ditto, two gudgeon ditto, and two roach ditto. Neither perch, sticklebacks, crayfish, or any beetles should be added. Tadpoles and little frogs look well. The objection to newts is that they will get out and run about the room; otherwise they are an attraction. Snails are a necessary evil; Paludina vivipara and Glutinosa amphibia are the best; half-a-dozen of each may be added. I have never found them devouring the vegetation, which Lymnea stagnalis, Planobis carinatus, and P. corneus are very partial to. Mussels should not be admitted. Do not be persuaded to add any other insects to your collection, as they will prey on your fish. Fish require feeding occasionally; small blood worms are the best food for the purpose. W. B.

Water in Aquaria Turning Green.—The slimy greenish substance is vegetation, and is caused by too much light. "T. B. M." should cover the glass most exposed to the light with blue tissue paper, which I think will meet the difficulty.—H. D. F. D.

—— Get a few water snails and put in. These will eat up the decayed green stuff, and so keep the water clear. You must be careful not to put too many in, as they will eat up the whole of the plants if you do.—C. Harxurot.

Making an Aquarium.—If "H. G., Sunderland," would kindly tell me where he used his tin for the aquarium, and for what purpose, I should feel much obliged, as I am about to commence one?—Ignorant.

Stocking a Small Aquarium.—I have an inverted bell-glass, 16 in. deep and 12 in. in diameter. What quantity of minnows, gudgeons, and bullheads can I keep in it? Where can I catch trumpet snails and pladden snails? What are they like? I should be very thankful to any one who would answer these questions.—A. H. C. W.

Mildewed Grapes.—I have found the following method efficacious in arresting mildew in the case of late Grapes:—On a still day, heat the hot water pipes as hot as the water will make them, and damp every part of the floor well with water, keeping all ventilation closed. Take a stone of fresh lime, and slack it in a

bucket, allowing it to boil well. Then reduce it with water to the consistency of thick paint, and into half a bucketful put three handfuls of flowers of sulphur. Mix all well together, and with an old whitewash brush put the mixture on the hot pipes. After the Grapes are all cut, it should be all washed off the pipes quite clean, or the result will be a crop of rusted Grapes the following summer.—J. S.

The Double-flowered Deutzia (D. crenata) is a remarkably fine variety of Deutzia. It is a much stronger grower than D. gracilis, and it produces longer racemes of flowers, which are quite double and pure white; they also last much longer and are far better adapted for cutting than those of the single kind. We have forced it here for the last two or three years, and find that it succeeds quite as well as D. gracilis. I do not consider it at all inferior to the best of the Bouvardias for any purpose, and I would strongly recommend it as a forcing shrub.—J. W.

Double-flowered Deutzia (D. crenata).

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Plants in Pots.—*Per doz.*—Arbor-vitæ (golden), 9s to 18s; Arbor-vitæ (common), 6s to 12s; Azaleas (ordinary), 24s to 42s; Azaleas (hardy), 18s to 24s; Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Aralia Sieboldi, 12s to 30s; Ardisia crenulata, 18s to 30s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Berberis, 4s to 9s; Bouvardias, 12s to 18s; Box, 4s to 9s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Clematis, 9s to 18s; Crocus, 1s to 2s; Crotons (in variety), 12s to 42s; Cyclamen (ordinary), 9s to 24s; Daphne indica, 48 to 6s; Deutzia gracilis, 9s to 12s to 30s; Dracæna (variegated), 18s to 60s; Ericas (hyemalis section), 6s to 18s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 30s to 36s; Hyacinths, 4s to 9s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Narcissus, 9s to 12s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 18s to 24s; Pelargoniums (scarlet), 6s to 9s; Pelargoniums (double), 6s to 12s; Primulas (single), 4s to 6s; Primulas (double), 9s to 18s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 9s to 18s; Scilla sibirica, 9s to 12s; Selaginella denticulata, 3s to 4s; Solanums, 6s to 9s; Tulips, 6s to 9s; Virginian Creepers, 6s to 9s.—*Per pair.*—Azaleas (large), 20s; Maiden-hair Ferns (large), 5s to 7s; Aucubas (berried), 4s to 6s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 10s to 15s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pears (fine dessert kinds), per dozen, 9s to 12s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 6d.

Vegetables.—*Per* 100.—Asparagus, 6s to 8s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 5s. to 6s; Parsley, 6s; Turnips (outdoor), 3s to 4s; Radishes, 6d; Herbs, 2d to 6d. *Per dozen punnets.*—Cress, Mustard, or small salad, 2s; Seakale, 36s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s.—*Per bundle.*—Celery, 1s to 4s; Horseradish, 3s to 6s; Salsafy, 6d to 9d.—*Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 1s 6d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Saveys, per score, 8s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 4s to 8s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

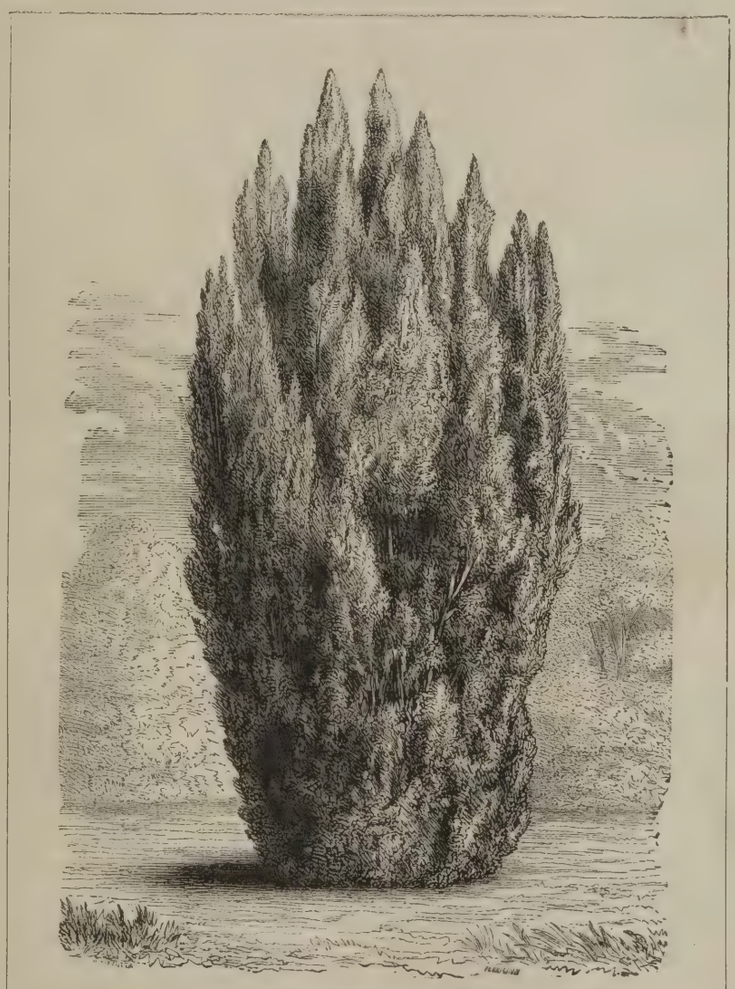
REGISTERED FOR TRANSMISSION ABROAD.

YEW TREES.

THE common Yew is a native of Britain, and, under favourable conditions, it attains large dimensions. There are also few, if any, trees which attain so great an age as the Yew; even the Oak can hardly be regarded as an exception in this respect, as the strong trunk and remarkably tough boughs of the Yew enable it to resist the power and force of fierce gales and storms which not unfrequently uproot or prostrate other trees, whether deciduous or evergreen, more particularly when such trees have become somewhat decrepit through age. The Yew being of slow growth, the annual layers of wood are necessarily thin, and this renders the grain remarkably fine, so that it is very valuable for cabinet-making purposes. From times the most remote it appears to have been customary to plant the Yew in churchyards; and possibly the oldest specimens of this tree are to be found on the sites of ancient places of sepulture, its sad and solemn aspect having, as it would appear, suggested to even the comparatively early races of mankind its adaptability to this purpose, and as a suitable companion to the Cypress. Notwithstanding, however, its gloomy appearance and funereal associations, it is at the same time a very ornamental evergreen tree, and one which tends to give a rich and warm aspect to the landscape wherever it is used. But, unfortunately, its dark green foliage is of a very poisonous character, and has on many occasions proved fatal to cattle; on this account it can seldom with safety be planted in parks or pastures, or in any situation to which cattle have access, unless such trees are so effectually protected as to be out of their reach.



THE IRISH YEW (TAXUS BACCATA FASTIGIATA).

It must at the same time be admitted that there are various instances of large Yew trees existing in parks stocked by cattle which have never been known to suffer from having browsed upon the green shoots of such trees, possibly from the circumstances of their being able to reach only so small a portion of such shoots as to have no apparent injurious effect upon them. It is, moreover, considered that the partially withered shoots or branches that may have been some time separated from the plants, such as the trimmings of a hedge, are more fatal than the perfectly fresh or green shoots. The fact, however, cannot be too widely made known that this tree is exceedingly dangerous to stock of all kinds.

Although botanists have classed the Yew among Coniferous plants, it is not cone-bearing in the strict sense of the word, but produces a red fleshy fruit or berry, which has been considered poisonous, although various species of birds eat it with avidity during severe winters, and do not appear to suffer any inconvenience from doing so, while the vitality of the seeds is in no degree impaired by the digestive organs of such birds; therefore they frequently vegetate where they happen to be dropped, and young plants are often found established in situations where they could hardly be expected to be found, such as on the face of precipitous cliffs, growing from fissures or rents in rocks, on ruined buildings, on the top of crumbling walls, and even between the forked limbs of large trees, or in any situation where moisture and the scantiest amount of soil or decaying vegetable matter exists. There are few species of trees or shrubs which so willingly submit to restriction of root and branch as the Yew; and many trees and hedges are in existence which, by annual clipping, have been kept to the same form and dimensions during very many years, and still preserve a healthy condition. There are perhaps few, if any, species of trees which can be transplanted when of considerable size with greater facility than the Yew, and this tree is consequently of very great value in the production of an immediate effect—often a desideratum. No plant is more suitable than the common Yew for the formation of hedges and screens in gardens and pleasure grounds. At all seasons of the year it is ornamental, and it is particularly so in spring or early summer, when the young shoots are beginning to be

developed, and are mostly af a rich brown or cinnamon colour, which has a very pretty effect. In winter and early spring such hedges afford a very effective shelter to tender plants of any kind, breaking or sifting the wind, as it were, and not forming cutting cold currents of air, as even walls of similar dimensions are apt to do. In the formation of such hedges, seedling plants should always be used, as plants propagated by cuttings or layers—particularly the latter—are often long before they form a leader or assume an upright form of growth, if indeed they ever do so. Even in a bed of seedling Yews considerable diversity of form is usually found among the plants, some of them assuming the more upright growth of Taxus baccata erecta; and these, although of increased value as single plants, are not so well adapted for the formation of a hedge intended to be kept close cut in, as it is desirable that the plants forming it should be similar in style of growth.

There are several varieties of the common Yew, such as the upright, already mentioned, the Irish Yew (Taxus baccata fastigiata), the golden-striped and the silver-striped common Yew; the golden-striped Irish Yew; also a weeping variety (Dovastoni), &c.; and there have been many exceedingly ornamental varieties of the golden Yew lately raised in Mr. Lane's nursery at Berkhampsted; and there are some fine examples of Yew in Mr. Waterer's nursery at Knap Hill. The Irish Yew is invaluable as a perfectly hardy ornamental evergreen, very suitable for cemeteries, as well as large or small gardens. In order that it should preserve its upright form, the plants should be grown upon a single stem, and care should be taken to prevent its branches being bent down by accumulation of snow, or by the action of high winds. A very remarkable effect is produced at Knap Hill and elsewhere by grafting some of the golden-striped varieties upon the Irish Yew at an altitude of 10 ft., more or less, as desired; the contrast between the bright golden-yellow of one and the dark green of the other is strikingly effective.

Clipping Box Edgings.—After repeated trials of clipping at different seasons, I am confident that the end of May or the first week in June is the best time for performing this operation, and for the following reasons, viz., that, although the Box is such a hardy plant, its young growths often suffer from spring frosts during May, and, by clipping at the time named, all irregularities of surface are removed; the young growth commences again immediately, and takes off that "straight-laced" appearance that always follows the use of the garden-shears. The young growth gives the edging a pretty appearance, and becomes thoroughly matured to stand any weather during the ensuing winner, which is not the case when clipping is deferred until the end of summer. The operation, although simple in itself, requires some considerable experience before it can be performed properly. For straight edgings, of whatever length they may be, we invariably stretch a line the whole distance to indicate the centre; then we take the desired width off either side, and level off the top with long clean cuts made by sharp shears. I have seen edgings laid in in almost every month in the year, and, with attention to watering, they have almost invariably succeeded; but I never saw them present an inviting appearance when the above date for cutting was very widely departed from. The greatest amount of injury is generally done through salting the walks to destroy weeds, when a heavy fall of rain floats the salt to the edging, thus most effectually destroying it. The next worst enemy to Box edgings is the foliage of garden crops or flowers overhanging them, and drawing them up weakly and blanched, so that they cannot withstand severe weather. Wheeling or treading on them also destroys them. Where proper attention, however, is paid to Box, the effect produced by it soon banishes from gardens all its so-called rivals.—J. G.

Club Mosses on Tree Stumps.—Pyramids of Lycopods are usually made by placing pans or flower-pots of different sizes one above the other, but good effects in this way may also be obtained by procuring good big stems of dead Tree Ferns, or of other trees which have a loose bark that will hold moisture. They should be potted, a small pan being secured on the top of the stump in which to plant the Lycopod; the margin left between the pot and the stump may be planted with Ferns, and a plant of the graceful Nephrolepis exaltata may be placed in the middle of the pan on the top. Any of the free-growing Selaginellas may be employed in this way, or Ferns with creeping rhizomes may be used with excellent effect.—S.

VEGETABLES.

OUTDOOR CUCUMBERS.

THERE are various expedients that may be readily adopted by those whose means are limited to shelter and protect outdoor Cucumbers in their early stages, and many handy contrivances suitable for cottagers have been designed within the last few years for the purpose of forwarding early vegetables; and I am quite convinced that a handy man, with plenty of time on his hands in the long winter evenings, could manufacture all he may require in this way. Small, light, square boxes, strongly nailed together, from 18 in. to 2 ft. square, with a couple of squares of glass to slide down to form a roof, will be as efficient, and, if kept painted, would last as long as more expensive substitutes. Frames, made of stout wire in the shape of hand-lights, and covered with oiled calico, are cheap and useful for placing over the plants on cold nights and days in the early period of their growth, and inverted flower-pots will always be found very useful on an emergency. Where a few barrowfuls of fresh stable manure or any other material that will produce a little warmth can be had, a start should be made about the end of April or beginning of May. They may either be grown in a continuous ridge or on slight hills about 4 ft. or 5 ft. apart. In the former case open a trench 3 ft. wide, and about 1 ft. deep, wheel the manure in, and cover it evenly with the soil taken from the trench, and, if possible, bring some fresh mellow loam, in which to sow the seeds. The manure should be made into a moderately firm compact ridge, from 18 in. to 2 ft. thick if possible, and 6 in. of soil on the top will be ample, as the young plants can be earthed up afterwards as they make progress. A trial stick should be plunged about 1 ft. in the bed, and as soon as the soil is moderately warm the seeds may be planted in groups (five or six seeds in a group), so that a hand-light, flower-pot, or whatever protection may be employed, will cover them. The groups or patches of plants may be placed along the top of the ridge, 3 ft. or 4 ft. apart. If the seeds all grow, the weakly plants can be uprooted, leaving only two or three at something like equal distances apart.

The Cucumber season in the open air is usually a short one, and a great deal of the future success in their development depends upon giving the young plants a fair start, taking care not to coddle and weaken them with too much warmth or too much covering. The covers may be kept on till the young plants push through, and then every fine day afterwards; if opaque covering be used they should be lifted off, of course placing them on again at night, and keeping them on during cold, windy days. With hand-lights, or any other glazed covers, a little ventilation only will be necessary on bright days to keep the plants in a hardy condition until the time comes for the lights to be removed; this should be done gradually, first tilting up the south side on two bricks, and in the course of a day or two the north side as well, letting the young shoots run outside; and as soon as the weather becomes fairly warm and settled the covers may be taken away, and the usual routine of stopping, pegging, and regulating the shoots must be gone through; this, however, is not so important a matter with open-air Cucumbers as with those altogether under glass. The shoots, of course, should be pegged down to prevent the wind from blowing them about and bruising them. Any strong shoot that shows signs of monopolising too much of the strength of the plant should be nipped at once at the point, and, during the growing season, if a little fresh loamy soil can be sprinkled over the surface amongst the growing shoots and round the main stems of the plants about once a week, it will benefit them considerably. Watering will at all times be an important point in their management; at the commencement of the season the water should have the chill taken off by the addition of a little boiling water, and as the quantity required will be small, this will not occasion much trouble; afterwards, when the plants are fully exposed to the air, simply standing the water in the sun for twelve hours will be sufficient. I need not say that liquid manure will be of great service to Cucumber plants when they commence bearing, nor yet that all fruit

should be cut when fit for use, unless seeds are required.

There are certain market growers that by a long course of selection have secured improved strains, but, as a rule, they do not care about parting with seeds; but what they have done others may do by using the same care in selecting the seed-bearing plants. In favourable situations Ridge Cucumbers may be grown—and, in fact, are grown—without any assistance in the way of bottom-heat beyond that supplied by the sun; but, as I have already stated, an early start, provided no sacrifice is made of health or vigour, means early production. I know a village in Norfolk where years ago a good many of the inhabitants used to plant their gardens principally with Ridge Cucumbers for the Norwich market, and the profit realised was always in proportion to the attention given, especially towards securing an early, healthy, and vigorous start. I am not much in favour of putting out plants that have been started in a hotbed in pots, though I am free to admit that if the seed be sown in single pots, and plunged in a gentle hotbed almost close to the glass, there is no reason why they should not thrive well, if carefully hardened off and planted out under handlights or other protection; but too often when raised in a hotbed in this way they are huddled up with other plants, and are ultimately turned out with a weakened constitution, and perhaps covered with insects, and half the season is gone before they recover sufficient strength to bear fruit, and should the season turn out unfavourable many will perish without bearing fruit at all. A crop of Gherkins may be raised for pickling purposes by simply sowing the seeds in patches, five or six in a patch, 4 ft. or 5 ft. apart, in well-prepared land early in June, without any special preparation beyond such good culture as is necessary for other crops of vegetables in garden cultivation.—E.

Growing Herbs.—No garden, however small, can be said to be complete without its bed of Herbs. With the exception of Parsley, Herbs are best grouped together in small patches in proportion to the demand, but yet at the same time each patch should be kept distinct. To keep them in strong, vigorous condition, they should be renewed by division, and in a few cases by seeds or cuttings about every two or three years. Some kinds, if they stand too long on one piece of ground, lose their vigour; and the winter, if severe, has more effect upon old plants than young ones, and may sometimes, by killing them off, occasion a scarcity; but where the plantations are frequently renewed this seldom or never occurs. Herbs are not at all particular as to soil or aspect, but one or two kinds, such as Tarragon, should not be planted in wet, cold soil if it can be avoided. From March to the end of May is a very suitable time for putting in cuttings, sowing seeds, or dividing the roots; and, if called upon to speak more exactly, I should say get all such done in April if possible. The cuttings or slips—as they will succeed well if slipped off with a heel—may be planted with a dibble, and of course should be planted firmly. In planting cuttings at all times and in all places the length of the cutting should be considered, and the hole only made deep enough for the base of the cutting to rest on the bottom. Inexperienced planters often unthinkingly practise what is termed "hanging" when planting either plants or cuttings with a dibble; that is, they make the holes deeper than the length of stem, and, consequently, the roots of the plant or the base of the cutting, as the case may be, hang suspended in the hole, and cannot obtain a sufficient grasp of the soil to become quickly established, and often perish in consequence. Of the herbs that are commonly used for flavouring, and which are indispensable, are Thyme (two varieties, Common and Lemon), which may be increased either by seeds or cuttings or division of the roots; Sage (green and red), which may be propagated by seeds and cuttings. Of Mint, several varieties are grown, but the Spear-mint is most useful, and is increased by division and by cuttings with a bit of root attached in spring or early summer; it will grow in any position, but improves by being transplanted occasionally. Fennel may be increased by seeds and division of the roots, and winter Marjoram mostly by division. The following also are not unfrequently found in gardens, and are often used to make cooling drinks and for medicinal purposes, viz., Rue, Horehound, Hyssop, Lavender, Balm, Wormwood, and Rosemary, all of which may be increased by cuttings and seeds. Camomile is best propagated by division of the roots, and it should be frequently transplanted in firm land. Amongst herbs that are highly esteemed for flavouring, and that are usually raised from seeds in spring—frequently assisted by artificial heat—may be mentioned Basil (bush and sweet), Summer Savory, and Sweet Marjoram. They should be sown, if no hotbed be at hand, the first week in May in light rich soil, in a warm, sunny place, be shaded and kept moist, and the young plants thinned out to 4 in. or 6 in. apart. If a small space in a frame or hotbed can be spared, sow a few seeds in a pot or pan early in April, harden the young plants off, and plant them out in May. By this means the plant will gain an early start. Chervil may be sown thinly in March, again in May, and again in August. All herbs that require to be dried for winter use should be cut just as they are coming into flower, and when quite dry they should be tied in small bunches, and hung up in some open, airy building or shed, and when thoroughly dried preserved in wide-mouthed bottles or jars and kept close. Basil and Summer Savory are tender, and should be cut and dried before frost is expected. When herbs are dried in the sun they dry too rapidly, and lose some of their strength.—H. O.

Plants for Out-of-the-Way Corners.—In large gardens will always be found neglected corners in out-of-the-way places. This is particularly the case under large trees (where few plants will thrive), on banks, &c. These positions may be considerably improved by the addition of plants which require but little attention. One of the most useful for this purpose is the Giant Cow Parsnip (Heracleum giganteum), a plant which produces noble umbrageous foliage and bears immense umbels of greenish-white flowers on stout stems, from 8 ft. to 10 ft. in height. It soon establishes itself, and care should be taken that it does not seed too freely, as it would cause much trouble. Altogether it is a most desirable plant, and wonderfully effective. Thistles (Carduus) are very handsome subjects for the same purpose, some of the varieties reproducing themselves freely. Galega officinalis should be found in every wild or neglected garden, as a few plants of it placed at intervals of 6 ft. or 9 ft. apart will soon establish themselves over a large area, as they seed profusely. The foliage is extremely elegant, the Pea-shaped flowers (pale blue and white) exceedingly pretty, and continue in perfection for a considerable time. The annual Sunflowers are most desirable. A few seeds of them sown in the most open places between trees and shrubs produce an effective show during the summer and autumn months. Evening Primroses (Œnothera) and Marigolds produce a profusion of bright, yellow flowers, and require no further attention than an occasional weeding. Phytolacca decandra is a hardy perennial, growing some 4 ft. in height, and bearing very handsome and peculiar spikes of dark crimson fruit. Centaureas, belonging to the hardy section, are particularly attractive, some having golden-yellow ball-like flowers, others blue, purple, &c., and all of them are of easy cultivation. Verbascums are also well adapted for shrubberies, and produce a profusion of singular Orchid-shaped flowers of various rich shades. Among plants that are more suitable for the front rank in shrubbery borders may be mentioned the following:—Nasturtiums, Antirrhinums, Canterbury Bells, Columbines, Foxgloves, Geums, Pyrethrums, Rockets, Sweet Williams, Valerian, Polemoniums, Glauciums, Lupins, Wallflowers. Polyanthuses, Pansies, Saponarias, Mignonette, &c. These are all extremely varied and beautiful, and require but little attention, reproducing themselves freely, and yielding a round of flower extending over several months. Beets, Fennels, and Acanthuses are most useful in the way of furnishing foliage, as are also Artemisias. With such plants as these, many a nook which is now neglected might be made attractive. The whole of the above require only the simplest treatment, and will well repay those who will give them a trial.

PANSIES IN POTS.

Few plants can be grown by amateurs in town or country with more success than the Pansy. They may be grown in front gardens, in boxes outside of windows, or in pots inside of windows. They merely require shelter from frost and snow during winter, and they may be grown in a sunless back yard. We lately saw an immense number of the most beautiful Pansies growing in small pots in a cold frame in Messrs. Carter & Co's nursery at Forest Hill. The plants were remarkably strong and full of flower-buds, showing what good effects might be gained in airy windows by having bushy plants in 5-in. or 6-in. pots. It is not too late to set about the culture of Pansies in pots, provided some good young plants struck from cuttings taken in July or August last were procured, well established in small pots. Pansies for cultivation in pots should be grown from cuttings and not from divided parts of the plants. Healthy, well-rooted cuttings make vigorous, stocky plants. It is best to begin in October or by the beginning of November, potting the plants into 5-in. pots, as this gives them a good start and enables them to get well established. The plants can be safely wintered in a cold frame having a dry bottom, as damp is the greatest enemy to the plants during the dead season of the year. All the water necessary during winter is just sufficient to keep the plants alive, and air should be given on all favourable occasions. If sharp frost sets in, some covering ought to be placed over the frame while it lasts.

Bedding Pansy.

Belgian or Show Pansy.

The next stage is that of shifting into the blooming-pots; this should be done about the end of February or early in March, selecting the size of the pots to suit the character of the plants; the largest can go into 8-in. pots, the smallest into 6-in. or 7-in. pots. This done, the plants should be encouraged in every way to make a free, stocky growth, taking care not to keep them too close and so imparting to them a drawn appearance. A cold frame, with the

plants resting on a well-drained bed, is the best convenience for the plants; the spot should be cool and somewhat moist, and if shaded during the middle portion of the day so much the better. Under such circumstances, and with due attention, the Pansies can hardly fail to do well. Just as the flowers are expanding some weak manure water can be given once in the morning, but having the plants raised on inverted flower pots, so that a quick drainage can be secured. A good compost for Pansies is made up of one-half good fibry loam, one third old rotted cow manure and horse droppings that crumble almost to powder, and the remainder well-sweetened and thoroughly decomposed leaf-mould. Those who make a point of growing Pansies in pots are always careful to keep up a supply of good plants from cuttings. The first batch of cuttings are taken in June, and when the plants from which the cuttings have been taken have done flowering, they are cut down to the ground, leaving any young growths that may be coming up from the roots. They are then top-dressed and set out-of-doors in a shady place, and finally turned out into the open ground in August, and planted into a prepared bed under a north wall or hedge. The soil for such a bed can be got from the siftings of the refuse soil from the potting bench, and the plants mulched with a little spent manure from a Mushroom bed, to keep the surface cool and moist. It is scarcely necessary to give a list of varieties. Any florist would be able to recommend and supply a suitable selection; only let the cultivator take care, as far as he can, that they are strong, healthy, and well-wooded plants, and as such worthy of his care and attention. A packet of seed sown now would give good plants in July and August from which to take cuttings, as well as giving a good supply for culture in beds or borders.

Flower of Double Pyrethrum.

Double and Single Flowered Pyrethrums.—A great improvement has been effected during the past few years in this family. The old Pyrethrum roseum, for instance, has been so improved that we have flowers equalling the finest of the French Asters, but with the aditional advantages of being perennial, hardy, and producing abundant bloom at a time when flowers are comparatively scarce. They are in perfection in May and June, and, with the Iris and Pæonies, form a glorious group. They are also invaluable for autumn decoration, for if cut down after flowering in June they flower again in autumn. They are easily propagated by division of the root and from seed, but the latter mode I would not recommended, as the proportion of good flowers from the best of seed is remarkably small. A good rich loam suits them best, although they will grow and flower freely in any good garden soil, and the more well-rotted manure is incorporated with the soil the better the plants grow and the more luxuriantly they flower. Mulching, especially in dry soils, is very advantageous, as it keeps the ground moist and cool. The following comprise some of the best sorts:—White and white shaded—Boule de Neige, delicatum, Madame Billiard, Nancy, niveum plenum, Olivia Argentine, Prince de Metternich, and Ne Plus Ultra; white with, yellow centre—Bonamy, Impératrice Charlotte, La Belle Blonde, virginale, and Voie lactée; purple and red—Mrs. Dix, rubrum plenum, Mons. Barrel, Brilliant, and Wilhelm Kramper; crimson—Michel Buchner, Miss Plincke, Modèle, multiflorum, Prince Teck, Progress, Emile Lemoine, and Marquis of Bute; carmine and pink—carminatum plenum, Charles Ballet, floribundum plenum, Gloire de Stalle, imbricatum plenum, Nemesis, fulgens plenissimum, Haage et Schmidt, and Iveryanum; yellow—Sulphureum plenum, Solfaterre; lilac and rose—Comte de Montbrun, delicatissimum, Dr. Livingstone, Gaiety, Galathée, Herman Stenger, Lady Blanche, Lischen, Minerva, Uzziel, and roseum plenum.—P.

HINTS ON CHRYSANTHEMUMS.

Cleansing from Dust.—If those who live in and around towns and cultivate Chrysanthemums, as nearly all do if they have the least bit of ground, only knew how important it is that they should be kept free from dusty deposits, their success would be much greater than it now is. This being the case, those who would have them thrive should not fail to give them a good drenching overhead at least once or twice a week during the summer and early in autumn; if they do this, the return will be much finer plants and display of bloom. This watering overhead is almost of as much importance as a supply of moisture at the roots, especially if the plants are growing near dusty roads or where the atmosphere is not clear and pure, as it seldom is in the vicinity of large towns and cities, where Chrysanthemums are perhaps more appreciated than anywhere else. In applying water to cleanse the foliage it is best done through a good syringe, as it then can be done with some considerable force. Failing this, a good shower from the rose of a water-pot will answer the purpose; but, however carried out, the washing should be thorough, as a slight sprinkling would only aggravate the evil by moistening the dusty deposit, and making it stick all the tighter.

Watering.—One of the reasons why we so frequently see Chrysanthemums in the naked, shabby condition they are at the time they should be looking their best, is from lack of water at the root, a state that generally brings on mildew; and if not this noxious parasite, the leaves become so starved that they die from inanition. This will be apparent to any one, as it is those low down on the stems and which get the least sap that go first; but if the plants are well fed, they will retain these till they become exhausted by flowering, when they die away naturally. When in active growth, it is surprising the quantity of water or liquid manure Chrysanthemums will take; and to ensure thorough soakings, it is a good plan to have the crowns of the plants slightly lower than the soil, that a small basin-like receptacle may be formed round them, that each may get its due share without any loss.

Growing in Trenches.—Where large specimens are required for pots, or for transferring to positions in open borders, to take the place of summer-flowering plants, a purpose for which they are well adapted, the best way is to grow them in shallow trenches; and if, in addition, they receive a slight mulching, there will not be the least difficulty in keeping them in the most perfect health. Plants treated in this way do well for lifting and transplanting under sunny walls of dwellings where it would be much too hot to grow them successfully during the summer, but where in autumn, when in bloom, the shelter is just what they require. With a very little trouble, therefore, the beauty of a garden may be considerably prolonged, as all that is necessary when the summer occupants are over is to lift the Chrysanthemums with good balls just after they have formed their buds; and if this is done during a dull, showery time, they will scarcely feel the removal. The finest and best plants I have ever seen in pots were managed in this way, and it is a plan of growing them I can strongly recommend, saving, as it does, a vast amount of labour and time in watering, besides yielding better results. Before taking them up, the thing is to see that they are thoroughly soaked a day or so previously, which will cause the soil to adhere to the roots better than it otherwise would. In potting, well-enriched loam should be used for the purpose, and the plants afterwards set for a few days on the north side of a wall, where they can be frequently syringed or watered overhead to prevent flagging. The rapid way they form roots soon enables them to set to work and get re-established, after which they bear the air and sun in a greenhouse or conservatory just as well as if they had been grown in pots all the season.

Growing in Pots.—When grown entirely in pots the most suitable soil for Chrysanthemums is good sound fibry loam, rather inclined to adhesiveness than otherwise; and if this can be had tolerably fresh, they will succeed best without any admixture whatever except a little thoroughly decomposed manure; but even this should not be strong, as it is always more satisfactory to give most of what stimulant they require in a liquid form, the advantage of which is that it can be applied when the plants most need it, instead of being unduly forced in their infant state, as many are by having too rich a soil to start with. By the end of May, early-struck plants will be ready for their final shift into 10-in. or 12-in. pots, and should after that be plunged on a firm bottom in loose littery material in an open, sunny spot, where, if well attended to with liquid manure and clear water, they will make grand plants by the autumn.

Small Plants.—The most suitable-sized plants for amateurs and others who only require them for greenhouse or window decoration may be had from cuttings struck in April; this affords ample time to grow fine little specimens in 8-in. pots, and such as these are generally the handiest for most purposes. Beautiful little plants may be had by propagating as late as May or June, and these come in capitally for window decoration indoors, or for the fronts of stages among others to fill in vacant spaces and afford more variety. In all cases the treatment and culture they require is much the same, as, unless planted out, they all do best plunged in sunny spots, well sheltered from the wind, which otherwise is sure to break them down.

Staking.—To prevent any risk from breakage by wind, they should be staked and tied early, but not in such a manner as to give them a stiff, formal appearance, which spoils half their beauty. If the main branches are firmly supported, that is all they require; and every stick used should be out of sight, as at best they are necessary evils and never any ornament—though, judging by the way they are frequently employed, many would appear to think otherwise. It should be borne in mind that to have the flowers of Chrysanthemums perfect they need early protection from frost, as they are very liable to injury in the bud state; and if allowed to stand out exposed then, a whole season's care and attention may be lost in one night. If housed, they should have an abundance of air during the day, and be kept as cool as possible.

S.

CULTURE OF STOCKS.

THE finest strain of the Ten-week Stock is that known as the large-flowering Pyramidal Ten-week. I have seen magnificent varieties of this come from imported seed—large vigorous-growing plants, branching freely, and producing a huge main spike of double flowers, with numerous branching spikes in succession. Where cut flowers are in request, a bed of these Stocks should be grown to assist in supplying them during the summer. The seed may be sown at

any time from the middle of March onward; but it is always well to get Stocks from the seed early, so that plants may be ready for bedding. The seed can be sown thinly in pans or shallow boxes, in a gentle heat, and as soon as the plants can be handled without injury they should be transplanted into other pans or boxes, and grown on quickly, at the same time taking care not to draw them so as to make them weak and lanky. There are many places in gardens where a bed or line of Stocks might be grown with advantage; only give them a good rich soil to grow in, and they will amply reward the cultivator. The German growers have a formidable list of kinds, many of which are more curious than showy. There are, however, sure to be sufficient leading colours among them, such as crimson, rose, purple, violet, and white, to yield distinct and pleasing hues. There is a strain of English selected Stocks known as Pyramidal, which are of tall growth, and remarkable for the large pyramids of fine flowers which they produce; but they are by no means so generally cultivated as they deserve to be. There is a very distinct type of Stocks known as Wallflower-leaved, which were introduced many years ago from the Grecian Archipelago, and which have shining deep-green leaves, not unlike those of a Wallflower. In all other respects the Wallflower-leaved type is like the ordinary German Stock. One of the finest varieties of this type, and at the same time one of the most beautiful Stocks in cultivation, bears the name of Mauve Beauty, a kind remarkable for its huge compact heads of pale lustrous mauve-coloured flowers. The same treatment as that recommended for the Ten-week Stock will answer for this type of Stock. The Intermediate Stock, as it is termed, though only a later-flowering selection from or variety of the German Ten-week, may be set down as a distinct type. It is used for pot-culture, to flower in early spring, the seed being sown in July and August. In growth it is dwarf and bushy, and, being very free-blooming, it is well adapted for cultivation in pots. As striking colours are best adapted for this purpose, the varieties may be said to be confined to scarlet, purple, and white. There is a fine strain of this type grown in Scotland, under the name of the East Lothian Intermediate Stock, where it is much used for beds and borders, the cool moist climate of that country appearing to suit it exactly. Instead of sowing Intermediate Stocks at the end of the summer, they should be sown about the end of March in a cold frame, and in May they should be transplanted to the open ground, in which they will flower freely through August, September, and October. In November the double flowers should be all lifted and potted, as it is unsafe to expose them to the risk of wintering in the open ground, and they continue to bloom more or less during the winter in a cold frame or cool house. They should be again planted out in March, when they will make fresh growth and flower all the summer. The single varieties are also lifted in November, and either potted or planted by the side of a south wall, where they are wintered, and flower and ripen their seed the following summer. They, too, require a rich light soil, in which they root freely. There are yet the Brompton Stock and the Queen Stock. The latter differs from the ordinary annual Ten-week Stock in being somewhat shrubby, of larger size, and of perennial duration. The principal varieties are the purple, scarlet, and white—the former being most generally grown. It is a great favourite in cottage gardens round London; and at this time of the year dense bushes of it may be met with—a mass of fine double purple blossoms. The seed should be sown in April and May, either in a gentle heat or on a warm border in the open air; the plants should be pricked out into beds and grown on during the summer, and in August and September planted out where they are to flower. A. S.

Flower Shows at Kensington.—The fortnightly meetings of the Royal Horticultural Society, held in the large conservatory, are well worth a visit by those of our readers who are interested in gardening matters. They afford opportunities of selecting the best plants and flowers, as well as of inspecting new and rare plants. On Tuesday, April 13, Messrs. Barr & Sugden exhibited a large collection of Daffodils, affording the best possible opportunity for any one wishing to make a selection to do so. Here all the known forms and varieties which flower at the season were represented, many of them rivalling in beauty some of the choicest Orchids; of which latter, by the way, an effective group was contributed by the New Horticultural Nursery Company (Mr. John Wills). What are termed greenhouse Rhododendrons were shown in fine flower by Messrs. Veitch & Sons, of Chelsea. These plants require a warm greenhouse; and when in flower, as the plants in question, they are very effective. The flowers are principally white, very large, and sweetly scented. The kinds shown were Princess Alice, Veitchi, and Sesterianium. A group of white-flowered show Pelargoniums from Messrs. Hayes, of Edmonton, were remarkable examples of good culture—being clothed with fine healthy leaves close down to the pot, and studded with fine trusses of bloom. The variety was Maid of Kent, introduced by Messrs. Hayes a year or so ago. We were told these plants had been grown by the aid of Clay's Fertiliser. A yellow-flowered Paris Daisy, called Chrysanthemum frutescens Etoile d'Or, shown by Mr. Howard, of Southgate, is an excellent amateur's plant. It is of easy growth, and bears abundance of large soft yellow flowers in a greenhouse or window all through the winter, and it is also an excellent summer garden plant. A stand of blooms of zonal Pelargoniums from Mr. Cannell, of Swanley, showed to what perfection the Geranium—the name the Pelargonium is best known by—has been brought. The flowers were remarkable for their size and variety and brilliancy of colour. Choisya tenata, a hardy plant suitable for walls, was shown in the form of a bush grown in a pot; the plant was about 2½ ft. in diameter, and covered with white orange-scented blossoms.

Caladium Belleymei as a Vase Plant.

House and Window Gardening.

Caladiums in Vases.—Caladiums make excellent vase plants for indoor decoration during the summer; but for this purpose the bulbs must not be started till about this time of year, and then in a temperature not exceeding 60° at night. When in active growth the temperature of an ordinary greenhouse will be sufficient, as if grown rapidly in a hot temperature the leaves will flag when placed in the room. They must be kept near the glass and slightly shaded from the sun; and when the vase or pot is well filled with roots it may be moved into the room where there is no gas used. The leaves must be syringed gently with tepid water occasionally to free them from dust. In a warm window Caladiums might be grown successfully.

Primula amœna in Pots.—This is one of the best of spring-flowering plants for windows or cool greenhouses. It will grow well in the shade, or it does not object to a little sunshine. The best way to secure robust groups of flowers and foliage in pots from this beautiful Primula and its varieties is to allow the clumps of roots to remain in the same pot two years together, and then break them up and re-pot after the foliage had died down. To get a fine show in this way it is desirable to have enough of stock to be able to break up clumps in alternate years, so that some established for the second year would always be ready to bloom. About nine good strong single crowns planted in an 8-in. pot will give a good head of bloom, but it will be far better the second year. I find that these Primulas make but little root growth before the blooming period, and, indeed, if it be desirable to shift at all, I think it is better to do it after the flowers have died down, as the chief root-work is done during the summer. Still, it is evident that these Primulas, like nearly all hardy ones, prefer rather to be starved than pampered, and probably throw up more flowers having brighter colours than is the case if there be an excess of root-room. Single crowns are now flowering freely in 3-in. pots, and do not care to be kept too moist; if each of these get a shift into 3½-in. pots presently they will then flower finely next year. In breaking up an established clump it is easy to select the strongest crowns and to pot those separately; the weaker ones can then be potted up thickly and will very soon make plenty of stock. Primula amœna forces badly, but under ordinary circumstances commences to bloom early in April. Some of the new seedling kinds are much earlier than others, one of the laciniated forms, named Pink Beauty, having been in bloom since the middle of March, whilst others are nearly a month later. This is a good time to get plants to start with, as then a good stock of plants may be got by next year.—D. S.

GARDENING IN TOWN.

If any one living in the country were to ask how to keep a garden of a few yards square gay with summer flowers, no better answee could be given than a reference to what is don in similar gardens in the locality. But in town—and especially in a great town such as London is—the conditions are so different that we look in vain for the gardens, large or small, that are gay in summer, or at any other time of the year, as country gardens are; and it is useless to refer the querist to what cannot be found. Whilst human life would seem—thanks, doubtless, to the innate capacity of the human frame to adapt itself to varying conditions of existence—to be as healthy in towns as in the country, plants are not so accommodating, and no power or ability has yet been able to cause plant-life to be as healthful and vigorous in towns as in the country. Plants cannot exist if deprived of the requisite light and pure air; and these two elements are just those that are found in towns most wanting. Even more essential are these elements for the production of flowers. Whilst plants, and especially deciduous kinds, may, because of the intermittent nature of their leafage, manage to exist fairly well in a dingy

atmosphere, flowers are absolutely the product of light; and if this be wanting, they either fail to develop or soon decay. Where there is wealth, a small town garden might be covered in with glass, and the plants beneath protected from the products of combustion that so largely permeate the air and befoul the leafage. Still farther, the recent experiments made by Dr. Siemens show that the electric light may be successfully substituted for the sun; and what that luminary is incapable of giving through the town murky atmosphere electricity may supply. This is one of the most remarkable discoveries of modern times in relation to plant culture, and it is specially in the formation of artificial town gardens that its benefits should be most successfully displayed. Wealth can also command what is perhaps the most practical method of furnishing a town garden, viz., a constant supply from some florist, who can produce flowers in quantity in some outside locality. There is nothing in this way that wealth may not command or the nursery trade furnish. Still, it is very easy to comprehend that none of these replies satisfy the querist, who doubtless wishes to have a garden cultivated under natural conditions, and filled with plants similar to those that beautlfy country gardens. If bloom and plenty of it be wanted, more is being asked than it is possible to gratify; but if to secure neat effects with what little bloom is possible, then nothing could be better than the conversion of the small garden into a miniature rockery, and planting it with hardy Ferns, carpeting it with various Sedums, and in all the intervening places planting, or rather plunging in pots, Fuchsias, Pelargoniums, Lilies, Lobelias, Echeverias, and several kinds of succulents, Balsams, Calceolarias, and in fact any half-hardy or hardy summer-blooming plants that could be obtained cheaply and in plenty in pots during the summer season. To have plants that could be easily replaced by others when the bloom was past its best would be an essential part of the arrangement. Amongst plants that do thrive fairly well in a town garden are the Creeping Jenny and the common Musk. To these may be added the double Convolvulus (Calistegea pubescens); the Canary Creeper, raised in pots and planted out, will do well as a trailer, if the plants are kept from the attacks of snails; and some of the dark-coloured trailing Tropæolums will be very effective. Mignonette and Nemophila will do well if turned out of the pots when strong into spots where there is plenty of root-room, but may be sown in the ground in vain. The irregular and elevated nature of rockwork not only throws the plants in a town garden nearer the light, but permits of their being washed clean, so far that all the soot so freely engendered by the town smoke is also washed from them more entirely than if growing on a low flat surface. The free use of the water hose during summer is an important element of success in town gardening, and this should be applied in the evening, as the greater amount of foulness in the air is engendered in the day; therefore, if the plants are kept clean during the night, they have much healthier conditions of life than have those which get the cleansing only that Nature gives.

A. D.

Suitable Plants for the Margins of Rose Beds.—For the outer edges of Rose beds, in addition to spring bulbs (Snowdrops, Crocuses, Narcissi in variety, and Scillas), Pansies Myosotis, Violas, and Daisies, kept in the reserve ground, and now, when the Roses have been pruned and mulched, planted at suitable distances apart, will keep on making a display for a considerable time; but it is with the plants that come into flower when the bloom of the Roses begins to wane that the best results will be derived; and by employing such as I have named above Rose beds need not have the shabby look which many so often present when the first flush of bloom is over. As will be understood from what I have said, there should be no attempt to plant so as to cover the ground, as this would interfere with the ordinary work in attending to the Roses, as well as with gathering their flowers; but enough may be done to give the ground devoted principally to Roses a cheerful appearance all through the season, without much cost in either labour or material or the least detriment to the Roses. —T.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 26.—Sowing Champion and Painted Lady Runner Beans; also Mustard and Cress; putting in cuttings of double White Primulas; planting a frame with Vegetable Marrows to come in early; levelling down Celery trenches and getting them ready for Peas; forking amongst Potatoes and getting them earthed up where required; giving all the newly-planted Cauliflower and Lettuce plants a good watering; also all newly-planted fruit trees and shrubs; potting offsets taken from old plants of Echeverias; sowing Cockscombs, Celosia pyramidalis, and French Beans; trimming and tying in shoots of creepers in conservatory; mulching Strawberries out-of-doors with short straw; levelling Celery land for Winter Greens; staking Hyacinths in beds out-of-doors; dusting Turnips with lime and soot, to kill fly; thinning frame Carrots; mulching Vine and Peach borders with rotten manure; digging land for main crop of Turnips; clipping Box edging; hoeing between all growing crops.

April 27.—Potting zonal Pelargoniums for conservatory decoration; also Musk, Celosias, and Calceolarias; Sowing Mignonette in pots, and a row of Sweet Peas; also sowing mixed flower seeds among Rhododendrons, another crop of Veitch's Perfection and Champion of England Peas, Spinach, and Radishes; making beds for sowing Cauliflower, Lettuce, and Cabbage seed; top-dressing Cucumbers where the roots can be seen on the surface; cutting flower-spikes from Rhubarb; sowing Canadian Wonder French Beans; potting off Coleus and Alternantheras; planting out Giant White Cos and All the Year Round Lettuces, and thinning out those left in the seed-bed to 1 ft. apart; digging out Celery trenches and getting manure into them.

April 28.—Sowing Autumn Self-protecting Broccoli; pricking off Celery, Stocks, Asters, and Violas; thinning out and hoeing amongst Turnips, and tying up Lettuces to blanch; potting Caladiums, Perilla, Sedum variegatum, Capsicums, Chilies and Vegetable Marrows; sowing Victoria Stocks, ornamental Grasses, Clarkias, Collinsias, and Nemophilas; also Turnips among bush fruit trees, and more Spinach between newly-sown rows of Queen of the Marrow Peas on a north border; planting Violets in beds, herbaceous plants, Myosotis, and Cerastium; also Sir Harry Strawberry plants that have been forced and duly hardened off; pricking off Saponaria calabrica, Daisies, Stocks, and Aubrietias; putting in cuttings of scented-leaved Pelargoniums; top-dressing inside Vine borders with cow-manure, digging land for French Beans, and watering Turnips and Cauliflowers; hoeing among Cabbage and Cauliflower plantations.

April 29.—Potting off Globe Amarantus, Lobelia, Bouvardias, Plumbago and Fuchsias; repotting Vallotta purpurea, Palms and Pomegranates, plunging the latter in a leaf-bed; shifting tree Mignonette and Celosias into 8-in. pots; also Tomatoes; sowing another batch of Balsams, Cinerarias, Calceolarias, and Cockscombs; also a bed of Walcheren and White Cape Broccoli, Marjoram and Sweet Basil; likewise Syon House Cucumber, Melons; planting Asparagus, Celery, Globe Artichokes, Vegetable Marrows, and Tomatoes; pricking off Marigolds, Lobelias, Asters, Phlox Drummondi, and other annuals in cold frame; putting in Pink and Carnation cuttings; plunging Tuberoses out-of-doors; top-dressing Lilies in pots; transplanting white Spanish Onions brought forward in pots; washing Roses on walls with Quassia-chip water, to kill green fly; removing the coverings off Apricot trees, and thinning the fruit where set too thickly; spawning and moulding over Mushroom bed under a north wall.

April 30.—Sowing Spinach, Cardoons, Early Snowball Turnips, and a little Endive; potting Balsams and Caladiums; looking over Cucumbers and Melons, stopping them, picking off all false blossoms, and earthing them a little where required; getting out drills and planting early-sown Leeks; thinning out Parsnips, and hoeing the ground amongst them; potting off Tropæolum canariense, and Primulas; shifting Standard Pelargoniums and Heliotropes into the pots in which they are to flower, and placing them in a late Vinery; also potting young Fuchsias; sowing Peas in trenches which had previously been heavily manured; also a few more rows of Broad Beans amongst Currant trees; planting Lily of the Valley, and Spirea japonica; also Gladioli in well-manured ground; fertilising Melons as fast as they come into flower, and keeping them at a temperature of from 68° to 70°; syringing Plum trees with soft soap and Tobacco-water in order to kill black fly; raking round Rose trees to make the ground available for sowing Mignonette seed; thinning Apricots and Peaches; taking up Broccoli and placing it in a cool cellar.

May 1.—Sowing prickly Spinach, Parsley, Chervil, Ridge Cucumbers, Scotch Kale, White Cape, Surprise, Champion, and Eclipse Broccoli, and another bed of Radishes and a little Cauliflower; planting Madame Falcot Roses; staking and tying Pelargoniums and Clarkias; also tree and other Mignonette; pricking out East Lothian Stocks; watering Beans, Carrots, Potatoes, Celery, and seed beds with weak guano-water; disbudding Peach and Nectarine trees out-of-doors; digging ground for late Peas; looking over Rose trees for maggot; netting Sweet Peas to keep off sparrows; sowing Asters, Stocks, Mignonette, and other annuals; looking over Peach trees on open walls, disbudding them, and washing them with Quassia-chip water in order to kill green fly; rolling down all gravel and turf that require it; hoeing amongst all growing crops.

Glasshouses.

Brugmansias.—Old plants of these that were cut back and started some time ago will now have made a certain amount of growth, and may, if they require it, receive larger pots, or have the surface renewed with fresh soil, keeping them in any available structure where they will get plenty of light and air, so as to keep their shoots short and stocky, which latter is essential to a vigorous head of bloom.

Greenhouse Dracænas.—These, especially while confined to a small or medium size can be used for so many purposes that they are almost indispensable, but it is necessary to keep up a continuous supply of young ones, as the larger stock will come in for use where smaller plants would not be so effective. When they get naked and leggy it is well to take off their heads, putting these singly in pots just sufficiently large to steady them, and subjecting them to a warm, confined, moist atmosphere, treatment under which they will soon root. The stocks, after the heads are removed, if placed in stove heat will before long push out a number of shoots that can be taken off as they get large enough and rooted, or a portion of the stems may be cut into lengths of 1 in. or 2 in.; these, if treated like cuttings in warmth, will break and form roots in a very short time, making useful little plants in eighteen months.

Arum Lilies are most serviceable when grown with single crowns that can be flowered in 6-in. pots; a plentiful supply of this size will be found of very much more use than large specimens. The flowers are of such a distinct and striking character, that one bloom is frequently as effective as two or three, and when sufficient numbers are grown to admit of their being brought into flower in succession, there is no difficulty in a supply being kept up from Christmas until late in the spring, but where Callas are grown in quantity it is best to turn them out in summer. Specimens that have flowered, consisting of several crowns, should now be taken out of their pots and divided, putting them in a row in a light situation in a well-prepared piece of ground about 1 ft. apart, supplying them sufficiently with water through the season until the beginning of September, when they can be taken up and placed in pots of the size above mentioned, in which they will bloom.

Large-flowered and Fancy Pelargoniums.—The blooms of these will now be fully formed, and will have made some progress, and be indeed in a condition to be benefited by the application of manure-water, which if used too early in the season is apt to cause a disposition to produce leaves at the expense of flowers. If sufficient ties and supports have not been already given to the plants to keep them in a presentable state, at the same time avoiding all stiff, formal training, this should at once be attended to.

Ferns.

Hardy Ferns.—Remove any old leaves that may be on deciduous kinds out-of-doors, and loosen the surface soil about them, making it at the same time clean and neat. Roots of these may yet be safely transplanted in shady nooks. Hardy Ferns wintered in frames and greenhouses should have their old fronds cut away, the mould on the surface of the pots cleared off, and the pots themselves either plunged in the Fernery in the open air or the plants turned out of the pots and planted in the soil permanently. In some cases it may be advisable to re-pot a few, and to keep them growing for conservatory decoration, or for planting in the outdoor Fernery, after their fronds have been formed indoors.

Greenhouse Ferns.—These are now starting into growth, and if any remain yet unpotted which require a shift attend to them at once. Stove Ferns, as a rule, are in a moderately advanced state; consequently, heat, moisture, and condensed light by means of shading, are necessary for the perfect development of their fronds. Filmy Ferns must now remain undisturbed, closely shaded, and sprinkled overhead every morning, and in the evening too, if the weather be very bright and warm. Maintain an equable temperature about these plants by tilting up the lid of the case in which they are growing a little during the daytime, and closing it at night.

Flower Garden.

For the next two months lawns will require to be mown once each week, and after that once a fortnight to the end of the season. Walks should always be rolled after heavy rains, and the weeds on them be kept down by hand-picking. It is not yet too late to turn and surface-gravel any that require that attention; but the sooner it is done, whilst the weather is showery, the better will they consolidate. Bedding out will now demand a large share of attention, both as to preparation of beds and plants.

Auriculas.—We are now in the midst of preparations for exhibiting our Auriculas—not wholly welcome work, inasmuch as they, as a matter of course, must consist of the best plants and the choicest varieties, and they do not always come home in quite such good condition as that in which they were before being removed from home. It is, too, a very anxious time for the cultivator. Some of the choicest kinds are very scarce, and if any accident happen to them it is sometimes difficult to get another plant of the same sort. As a set-off, however, to all this, an exhibition of this kind affords an opportunity for growers from all parts of the country to meet together and discuss matters relating to Auriculas. The general public also have an opportunity which would not otherwise be afforded them of seeing the plants. As Auriculas go out of bloom, if it be not intended to save seeds, the flowers should be pinched off as soon as they fade, leaving part of the footstalks. If the stem be broken off the portion that is left does not dry up, but dies off, moist down to the centre, and sometimes kills the plants. Now is the time to hybridise, in order to obtain seeds that will produce new and good varieties. Green-edged varieties should be crossed with flowers of the same section; grey-edged with grey-edged, and so on. In the case of alpines the light-edged flowers with white centres should be crossed with others of the same class. Shaded-edged flowers are most esteemed, and such only should be used for parents.

Hollyhocks.—All these ought to be planted out by this time in beds or borders; even the spring-propagated plants should be put out at once, if not already done, and great care should be taken in planting them, especially if the spikes are intended for exhibition. Some good loam mixed with a third part of rotten manure should be placed round the roots. It is by paying attention to minute details that success is achieved.

Pansies.—These require continual attention. Now wire-worm and the leather-coated grub will be troublesome underground, and must be looked for if the beds indicate their presence. A show Pansy will continue to flower until the character of the blooms are so deteriorated that the variety cannot be recognised; in that case pick all the blooms off and surface the soil round the roots with rich compost; this will restore the blooms again to their original size and quality.

Tulips.—These are now becoming interesting; their flower-buds are rising strongly. They are later this year than usual. Ours are fully exposed to the weather, and, though frosts by night and keen cutting winds by day have been the rule rather than the exception, not a leaf or bud is injured. If the surface of the beds has not been dressed with rotten manure, that should at once be done. The different species of Tulips that have been introduced recently are very interesting, some even very beautiful, and they form a distinct and pleasing feature in beds or borders. They can also be grown in pots in cold frames, using light soil in which to plant them. The bulbs of some of them are small, and therefore they do not require to be covered deeply.

Hardy Fruit.

Peaches and Nectarines should now be disbudded, and if done early it may be done finally. As soon as the fruit is set it will be advisable to thoroughly syringe or wash the trees with the garden engine in order to cleanse them from fallen blossoms; and if aphides, appear, dust with Pooley's Tobacco powder or syringe with Tobacco water. Currant bushes are frequently, even before the foliage has fully expanded, attacked with the blue aphides, for the destruction of which nothing is better than frequent washings with clear water. Young, newly planted trees are apt to grow too strongly, more especially the uppermost shoots. In order to check this tendency it is well to stop the leading shoots twice or so during the season; a more equable distribution of sap to all parts of the tree is thus ensured, and therefore a more even growth. Such remarks are not only applicable to newly-planted Apricots, but to all other kinds of fruit trees, and not only to wall-trained trees, but also to nearly all others. Still, let the trees be sheltered nightly; the fruit will swell more kindly by avoiding extremes of either heat or cold, therefore, for the present, the blinds should be down for a couple of hours during the brightest sunshine.

Kitchen Garden.

A sowing of French Beans may now be made on a warm border. It is not, however, advisable to put in many until the beginning of May, as they are liable to be injured by the weather; neither is it advisable to sow at all until May where the land is of a cold retentive nature; but in such localities, when this vegetable is particularly desired early, a fortnight may be gained by at once planting a couple of Beans in 4½ in. pots, and keeping them in a frame until the third week in May, after which there will be little danger from frost. The seeds of early sowings out-of-doors do not cover more than 1 in., for if sown deeply, and the weather becomes very wet, they will rot. The Red Flageolet is one of the best of dwarf Beans, being good in quality and a heavy cropper. A few Runner Beans may also now be sown in a dry situation, but do not at present risk too many. Ordinary Pea-sticks, say 4 ft. in height, will answer very well for Scarlet Runners, pinching off the points of the shoots as soon as they get to the top of the support, and in this case the rows do not need to be more than 4 ft. apart. They will also do well without any sticks. If the rows be planted 3 ft. apart, the seed 9 in. asunder in the rows, and they are simply allowed to live on the ground, they keep breaking out and flowering all through the season, and the quantity of Beans which they produce would not be credited by those who have not seen them grown in this way.

A few more Turnips may now be sown, and for the general crop none are better than the Red-topped American Stone, already recommended for the earliest sowing. As with most other vegetables, it is much the best practice to grow Turnips in rows. Sowing in this way takes a little more time, but any loss in this way is saved many times over by the facilities given for the use of the hoe in place of hand-weeding, which must, in a great measure, be resorted to where such crops are sown broadcast. Another sowing of the different sorts of Broccoli before advised should now be made; also one of Cauliflower, both Summer and Autumn Giant. More Lettuces should likewise be at once sown; and now and all through the summer these should be sown in rows where they are to be grown. The ground for them should be well manured; the rows should be 15 in. apart, the seeds put in thinly, and, when large enough to handle, they should be thinned out to 1 ft. or 15 in. apart. Another sowing of Broad Beans may be made where these are required late, but such as are put in now will not bear so well as those sown earlier.

GLASSHOUSES & FRAMES.

GREENHOUSE PLANTS FROM SEED.

After Azaleas, Camellias, Epacrises, and similar plants are over, we look in a great measure to Fuchsias, Pelargoniums, and that class of subjects, to take their places; but these do not afford variety enough to be satisfying and effective. I purpose, therefore, to give a list of a few plants that may be raised from seeds sown now in time to supplement them.

Celosias.—Foremost in point of usefulness are Celosias, but many of the strains of these, like those of Balsams, are comparatively worthless. If, however, those having the fine pyramidal habit peculiar to some, and the lovely light feathery inflorescence which such produce be obtained, more ornamental objects than they are cannot be desired; and not only are these most valuable for furnishing purposes, but they are equally so for yielding cut bloom, a few sprays of which are a great ornament in any vase, as they are both light and elegant-looking, and, in addition to this, last a considerable time in perfection. By getting a mixed packet of seed, many shades of colour may be expected, as they vary from bright crimson to delicate pink, and there are others that bear soft yellow plumes; so that the contrast between the whole when selected and judiciously arranged is most effective. Being subject to red spider, they should be grown in a moist heat, and kept freely syringed till their flowers appear, when they will stand safely anywhere in the ordinary temperature of a greenhouse or room till quite late in the autumn; and if wanted beyond that time they do well in the warmth of a stove. The old Cockscomb, from which these Celosias originated, is a very stiff, formal-looking object compared with such graceful-habited plants as these. Nevertheless, they are very showy-looking, and have their admirers; and where it is desired to grow any of them they should be sown and managed in much the same way as recommended below for Balsams, so far as the potting, plunging in heat, and treatment of that kind is concerned.

Balsams are generally grown, and little need be said about them except that the finest strains should be procured, as the inferior kinds are not worth house room. To grow Balsams well, the seed should be sown in brisk heat, to induce free germination; and immediately the plants show themselves above ground it is important that the pots or pans containing them be set on a shelf, or elevated in some other way, so as to bring them close up to the glass to prevent etiolation. As soon as they stiffen a little, they will be fit for potting off singly, which should be done in light rich soil in small pots, and the plants returned to a similar position, there to remain till they are well rooted and ready for shifting. In doing this the best cultivators always drop them a little lower at the collar, the object being to bring the bottom branches well down, that they may be pegged or tied out, and thus furnish a good base towards forming a perfectly symmetrical specimen. In cases where room cannot be spared in a light house in which to grow them, a pit or frame answers the purpose very well after the weather gets a little warm. To keep them sturdy and short-jointed under such conditions, they must have plenty of air on all favourable occasions; and, to prevent the attacks of red spider, heavily syringe early in the afternoon, just before shutting them up. Their precocious habit of blooming renders it necessary to pick off the first buds that show if fine large plants are aimed at, by doing which those that come after are larger and more regular, and, as they appear in quantities together, make a far better display. The soil for potting in after the earlier stages cannot well be too rich, and may consist of one half loam and the other part thoroughly decomposed mild manure that has been laid up for a long time; but if such as this is not at hand, leaf-mould may be substituted, as stimulants can be given as often as desired in a liquid form.

Browallia elata.—There is another annual to which I would call particular attention as specially deserving pot culture, and that is, Browallia elata, which bears innumerable small blue flowers, of great service for cutting and working up in bouquets, as the sprays are just of that size and character to suit them for that purpose. A batch sown now, and grown on anywhere in a cold frame till the end of May, and afterwards outdoors, will be gay by September; and another lot raised in July will last in bloom the whole winter through. At that season, however, the plants require heat, and if in that of a cool stove, there seems no end to the flowers they yield. Being of a fragile habit, we grow three in a 7-in. pot, where they are placed triangularly near the sides, and thus make fine masses, fit for the embellishment of window recesses, or any other purpose for which they may be required. Rich, light soil suits them best; and as they require plenty of water, free drainage should be given, that it may pass off quickly without injuring the roots.

Schizanthuses.—These are very beautiful annuals, and make splendid pot plants, growing about 2 ft. high, and bearing flowers very much resembling butterflies with outstretched wings, the petals being blotched and spotted much in the same manner those insects are marked. The variety having these characteristics is named papilionaceus, on account of the similarity referred to; and there is another kind, of quite different habit, equally deserving of cultivation. This is known as Grahami, the blossoms of which have more the appearance of some of the choice Orchids, and are of great value for cutting. By sowing either of these in heat at once, they may be soon grown on to the flowering stage; and if another sowing is made towards the end of July they may be had in beauty nearly the whole year through. As with the Browallias, the best way

is to put three in 7-in. or 8-in. pots, by doing which they furnish up well, and produce a much better effect.

Torenia Fournieri.—Those acquainted with that old highly ornamental stove plant, Torenia asiatica, will require no further recommendation of the first-named than to be told that it is almost the exact counterpart of that once popular variety, so far as regards the form and colouring of the flowers; but, instead of being a creeper and requiring stove heat to grow it in, T. Fournieri has more of a shrubby habit, and only requires the temperature of a greenhouse, where it blooms profusely and continuously the whole summer through. To get it up to this stage, however, it needs some warmth, such as may be afforded in any pit or frame containing a bed of fermenting material, a situation in which it succeeds remarkably well, as it does also later on in any cold frame, if shut up early in the afternoon, so as to benefit by the assistance that may be obtained from the sun. To induce the seed to germinate freely, the best way is to cover the pot or pan containing it with a piece of glass, shaded for a few days with paper, which keeps the soil more uniform in respect of both heat and moisture. This is an important matter with all small tender seeds, but one that is too frequently lost sight of; and a want of due observance as regards this at the outset is the cause of many failures. The soil best suited to grow this Torenia is a mixture of loam and leaf-mould in about equal proportions, or, failing the latter, refuse peat answers the same purpose, and may therefore be used in its stead.

Ipomœas.—Of these there are many varieties, all more or less lovely in the rich markings of their flowers, which bear a close likeness to those of the Convolvulus, but are much larger and more brilliant than they. Placed along the front of a greenhouse under the rafters, and trained up beneath them on wires, they have a most ornamental appearance, as they have also up pillars or other supports in a conservatory, if the positions assigned them be not too shady, as sun is requisite to induce them to grow freely and open their blossoms. Seed should be sown in strong moist heat, and the plants grown on quickly in the same for a time, till they are large enough to be hardened off and transferred to their permanent quarters, where they will require plenty of water to keep them clean and free from red spider.

Petunias.—These make a splendid display in pots, especially if the new double varieties are obtained; but to have any of them in real perfection they must either be grown outdoors after May, plunged in some sunny spot, or in very light pits, or housed where they can have the solar rays without shade, and plenty of air to keep them from drawing. Managed in this way they come very stiff and short-jointed, and are therefore much more floriferous than they are when the shoots are sappy and soft. Besides being so gay and effective in pots, Petunias make capital basket plants, the single kinds being best adapted for this purpose, on account of their stems and habit being less stiff, which enables them to droop over and depend more naturally, without pegging or interference to bring them into that desirable condition. Seeds of Petunias germinate quickly, and the plants, under good treatment, are large and strong enough to flower in about nine or ten weeks from the time of sowing. Stiff fibry loam suits them best, in which they should be potted somewhat firmly.

Mimuluses have been so much improved of late years that they are thoroughly deserving of a considerably extended cultivation, as they are not only exceedingly showy, but they are likewise very enduring, and with plenty of water and partial shade they will continue blooming for months. For the embellishment of windows I know of nothing more telling and useful than these; they are just at home either in baskets or pots. Some of the kinds are very curious, having hose-in-hose flowers; and the majority of the different varieties are rich in colour, and very varied in the character of their quaint markings.

Grevillea robusta.—If foliage plants are wanted to disperse among the flowering, seeds of this, Acacia lophantha, and Zea japonica variegata should be sown, the two former being quite as elegant in point of appearance as any Fern; and the Zea, with its bold leaves so beautifully marked, is a striking object if stood well up, that it may show out here and there on the stages above others. The Grevillea and Acacia will be found to germinate more readily if the seeds are soaked for twenty-four hours in milk-warm water to soften them a bit, when they should be sown in light soil and placed on a hotbed. S. D.

Standard Fuchsias.—Fuchsias grown in the form of standards are for many purposes better than bushy plants, as they can be placed among small plants; and their heads of bloom standing boldly out, show themselves off to the best advantage. Standard Fuchsias are easily grown; all that is needed is to start with strong cuttings, train them in an upright direction to a stake, and keep all the side-shoots pinched off. When the desired height of the stem is attained, pinch out the growing point, and a bushy head, may, by stopping the shoots several times, be quickly made. A thick head, is, however, not

Standard Fuchsia.

so effective as a light one composed of long graceful shoots.

Standard Heliotropes and Habrothamnus.—Standard plants are often considered in themselves not very striking objects, but they are most useful in combination with others of a dwarfer character, as by their use the disagreeable even surface frequently present in greenhouses and conservatories is avoided. The above two subjects are particularly adapted for growing in this form, and the present is the most suitable time through the season for preparing them. They may consist of established plants, headed down to near the collar; when broken into growth the shoots should be thinned to a single stem, which should have a stick for its support, and should be run up to the height required, which may be from 3 ft. to 5 ft., according to the size or description of the structure which they are intended to occupy and the plants with which they are to be associated when in flower. After the desired height has been reached stopping must be resorted to, and continued until the heads have attained a sufficient number of shoots. If headed-down plants like these are employed, as soon as they have fairly broken they should be turned out of the pots, a portion of the old worn-out soil should be removed, and more root-room should be given them, using tolerably rich soil. Thus managed, useful-sized examples may be had by autumn, at which time their flowering will be found very acceptable. If established plants be wanting, it will be necessary to proceed in the usual way with cuttings, which, if treated liberally as regards pot room, will soon reach a serviceable size. In reference to the Heliotrope, so much esteemed for its perfume, it is doubtful if any of the new varieties are better than or equal for this purpose to the old original kind, which still appears to have the preference with growers for market.

Balsams.—As it is now time for sowing the seed of this beautiful greenhouse annual, a few lines as to its culture may not come amiss to some of my brother amateurs. As the Balsam requires the aid of a hotbed to start the seeds in, the third week in April is soon enough for sowing. In preparing the compost for the seed pan or pot it is best not to get it too heavy, as the small rootlets cannot then get down. The mixture I find to suit best is one-half good fibrous loam well chopped up, and one-half leaf-mould nicely sifted. As soon as the young plants appear 1 in. above the pot take them out of the hotbed and place them in a cold frame for a few days until their second pair of leaves appears; then pot them off singly in 3-in. pots, using similar compost as for sowing the seed in. Care must be taken not to pot too firmly. Place the plants back on the hotbed for a few days until you see they have made a fresh start; then take them out, place them on a shelf in the greenhouse, or place them in a cold frame facing south, where they will have the benefit of the light and sun, giving more air as the days increase in length and the sun in strength. Watering must be carefully attended to; if they are allowed to remain dry the lower leaves will fall and give them an unsightly appearance. Syringe them overhead in the afternoons of bright days; they will not only be benefited by it, but it will also help to ward off green fly. By this mode of culture I have grown them on, and flowered them in 8-in. pots, with the stem just above the rim of the pot as thick as a spade-handle, 18 in. high and 15 in. through, one solid mass of flower, which is suitable either for the window or the conservatory.—D. W. B.

Tree Pæonies in the Conservatory. Plants of the Tree Pæony forced into bloom at this season of the year form attractive objects in the Conservatory at Pine-apple Place. They consist chiefly of plants with a single stem 12 in. to 15 in. high, and surmounted by large heads of blossom. The variety chiefly grown is one named P. arborea Elizabethæ; it bears very large heads of flowers, which are well formed, very double, and of a bright rosy-pink. In order to get Pæonies to open their blossoms perfectly, little heat must be given until the bloom-buds are visible, when they may be placed near the glass in a warm temperature with every prospect of success. On account of the attractive character and longevity of the blossoms of the Pæony, they might be grown for conservatory decoration, either in the shape of large or small plants, to a much greater extent than is at present the case. Small plants such as those described are among the best subjects for vases in rooms.

Cordyline indivisa.—This is by no means an easy plant to cultivate, but when well grown it is one of the most graceful. Its leaves are of a pleasing bronze, and maintain their character under good culture for years. At one time it was rather scarce in nurseries, but during the last year or two it has become fairly plentiful. The best treatment is the following: Procure a nice healthy plant in a 4-in. pot at once, and if the roots are fresh and healthy remove it at once into an 8-in. pot; but if they are not strong then a 6-in. pot will be sufficient for the first shift. The most suitable compost is fibrous peat and loam in equal proportions, broken so as to pass through the meshes of a ½-in. sieve, but with the fine portions sifted out. To the rough pieces add an eighth of potsherds and charcoal, broken to the size of Peas, and sufficient sand to make the whole perfectly porous. Let the pots be perfectly clean, and drain them thoroughly. In potting, take care to keep the base or collar of the plant well rounded up, and press the soil firmly. Place the plant in a warm and shaded part of the greenhouse, and water cautiously until such time as the plant starts into free growth, and then a copious supply may be given. If the plant gets into free growth, a second and perhaps third shift may be given during the season; but it will not be advisable to shift later than the end of July, as it is important that the pot should be full of roots before the winter commences. As the light decreases, gradually diminish the supply of water, so that the plant may be kept comparatively dry during the winter. The best situation for the plant through the winter will be a dry shelf, where there is a free circulation of air, but no cold draughts. In such a situation, with judicious

attention, the Cordyline will grow on for years. —A.

ANSWERS TO QUERIES.

1930.—Begonias and Cockscombs.—Begonias can be grown easily in any ordinary greenhouse if it be kept fairly warm at this time of the year (that is, a temperature of about 60°), and will do without artificial heat in the summer months. Many kinds do well planted out in beds in the open air. The seed should be sown in a gentle heat in shallow pans, and in fine sandy sweet soil. If good it will germinate in a week or two, and the chief requisite of good cultivation is to keep the plants growing on without check till they come into bloom. Cockscombs should be sown and raised in the same way, but, as it is of the first importance the plants should be dwarf, it is a good plan to grow them on in a warm frame near to the glass, giving a little air in the daytime. Some growers to keep them dwarf make cuttings of the plants and re-root them, but that is of questionable advantage. The needful cultivation may be summed up in the words—rich soil, enough pot room, a gentle heat, plenty of light, and kept constantly growing.—A.

1925.—Begonia Seed not Germinating.—There is too much reason to fear that Begonia seed sown in entire accordance with the instructions given on the packet must have been bad at the first. It is, however, often easier to read such specific directions than to follow them to the letter, and, therefore, after all the seed may have been good, but it was perhaps swept off by woodlice or by a slug in a night; or it may have been too often watered, or the temperature was not high enough, or a thousand things may have happened to it. No doubt it will be wise to get more seed and sow again, and probably as the season is more advanced better results may follow.—D.

1926.—Green Carpeting Plants.—Sedums are amongst the best of carpet plants, and propagate so rapidly that a carpet is soon obtained if merely single points be pricked in over the surface of the bed. The two best are S. lividium (green) and glaucum (silvery). Both kinds are remarkably neat and effective, and the diversity in the hues of the foliage is a great recommendation. Another capital carpet plant is the Veronica repens, a close, compact, creeping kind that forms a singularly dense covering. It is of a deep green colour, and in the spring is literally smothered with tiny white flowers. This is also propagated by division, and increases with great rapidity. Spergula pilifera may be raised from seed or propagated by division, but although a very fair carpet plant, it is not so good as the others named. The Russian Pyrethrum gives a capital covering, but is a deep-rooting plant, and is better fitted for rockwork, where it may remain permanently. The dwarf mossy Saxifrages will do very well also, but they increase more slowly. All these plants will do fairly well either in shade or in sunshine. The old-fashioned Creeping Jenny and double Daisies will also make carpets of foliage, and at the proper season bloom also.—D.

1930.—Caterpillars on Cabbages.—The best way of destroying caterpillars on Cabbages is to hand-pick them off and drop them into hot water, or kill them in some other equally expeditious way. To prevent caterpillars appearing, look under the eaves of buildings and under coping and other warm sunny corners in summer and autumn, and destroy the insects in the chrysalis state. The name of the common black slug is Limax ater. Lay brewer's grains in little heaps about the beds where they are troublesome, and visit them at night with a candle. Freshly-slaked lime dusted about very early in the morning as soon as it is light will reduce their numbers.—E. H.

1788.—Old-fashioned Flowers.—The best way to cultivate the varieties of the common Primrose is to provide for them a bed of turfy loam, such as can be dug from an old pasture; or failing that, old mellow garden soil such as would grow first-rate Celery; if the latter, it should be mixed with about a third of leaf-mould rotted to powder, peat, or old hotbed manure rotted to dust. At least 18 in. of soil should be provided, and the drainage must be good. The best position is one exposed to the sun in winter and spring, but shaded from the hottest sunshine in summer, and sheltered from cutting winds. If there are no deciduous trees to give the necessary shade, a shelter can be easily contrived by means of summer climbers, such as Sweet Peas, Convolvulus, or Scarlet Runners; the position must not be made confined or damp. An inch of half-rotten leaves should be placed on the bed every autumn, and slightly pricked in with a fork. The Wood Anemone may be found growing wild in the thicker parts of the same coppices in which Primroses thrive, and therefore may be planted in the more shady parts of the same border. Pansies will grow plant and plant with the Primroses. Polyanthuses and Auriculas require the soil a little heavier, but otherwise the same treatment will suit them. Violets require the soil still more inclining to clay, but the same annual dressing of leaf-mould. The plants described would seem to be starving; the new roots should spring in the autumn from the collar of the plants immediately under the leaves. There must be something wrong with the soil or situation if Daisies refuse to thrive, as they will grow almost anywhere except in a stiff intractable clay.—J. D.

1970.—Grubs on Lawns.—This is the grub of an insect resembling the Daddy-longlegs,

A fine Vase Plant (Cordyline indivisa).

but about half the size, and darker in colour. I do not remember noticing it until about three years ago, since which time it has increased greatly in the suburbs of London. If it goes on increasing in numbers, it will be much more destructive to lawns than the Daddy-longlegs; for, whereas the latter comes to the surface to feed in the night and can then be destroyed, this seems to remain underground until March or April, when it appears as described, to search for dry crannies in which to assume the chrysalis state. It seems to feed exclusively in the late autumn and during winter. Catch and kill is the only way of getting rid of them. This class of insect is the favourite food of the swallow, and the absence of these birds in towns is the cause of their great prevalence.—J. D.

1924.—Tortoise in Vinery.—I have kept a tortoise about six years in a Vinery, and never saw that it did the least harm to the Vines. It eats readily Mustard flowers, Lettuces, and leaves and flowers of the Dandelion; but its favourite diet is Buttercup flowers, never seeming to tire of them. I feed it once in the day when the sun shines, and it has access to a pan of water, but I never saw it drink; it also likes some loose soil to burrow in, and some hay to sleep in. I think the tortoise will stand any amount of heat, though I often put mine in a cold frame during summer, with hay and shelter in one corner, as he does not like to be rained upon. I had it to destroy insects, but believe it is a perfect vegetarian. I winter it in the cellar amongst some hay.—E. Jackson.

1891.—Cobæa scandens from Seed.—The plants are probably kept too moist, especially in the winter. I had one which lived and grew in a 12-in. pot, and almost refused to die, although it had no water for six weeks. Several shoots of it which had found their way amongst other climbers seemed ambitious of realising *Fun's* facetious invention of the creeper which grew and flourished, though its stem was severed, because it could not see its root, as they remained green and growing some weeks after the pot containing the roots was removed. The plant was in an unheated greenhouse, exposed to the whole sunshine after 12 noon.—J. D.

1981.—Wild Flowers.—The Wood Anemone may be found in profusion in the coppices between Wrotham and Stanstead, in Kent. Seal Chart and the woods between Seal and Igtham, in the same locality, are also likely places for the flowers named, the most shady places for Wood Sorrel. Wild Hyacinths may be found by the footpath over Shooter's Hill to Eltham. The western slopes of Hayes Common, in Kent, should also be visited. I have only been there in the late autumn, but the locality seemed likely. The Wood Anemone flowers in March or April, the wild Hyacinth in April and May: both these plants are in cultivation, and may be had from nurseries. The Wood Sorrel is also in flower now in warm localities, but in cold ones it will not flower much before the end of June.—J. D.

1969.—Painting Greenhouse Floor.—Procure from a chemist some commercial hydrochoric acid and mix one part with ten-parts of cold water, taking care not to inhale the fumes of the acid, as it occasions a kind of colic. This acidified water will remove any deposit of carbonate lime, which would tend to make the tiles dirty-looking; also it decomposes any green stains. I would advise, after the use of the solution, a good swill down with clean water, drying the floor with a flannel.—A. B. T.

1923.—Peas with Beetles Inside.—Considering that there are something like 500 species of weevils or beetles inhabiting Britain, all living upon vegetable substances, the wonder is that so little is known about them. The species named by "Gardener" is probably one of the Pea weevils (Cureulis lineatus), which not only eats the seed but attacks the plant when above ground. In the latter case dustings of soot, by making the plants distasteful, often causes the beetles to move on.—E. H.

1921.—Keeping old Primulas.—Move to a well-ventilated cool frame on a coal ash bottom, cut away all old flower spikes and dead leaves, re-pot towards the end of the month, removing some of the old soil. The new soil should be rough and porous: about equal parts of turfy loam and peat or leaf-mould, with some sand and crushed charcoal. Shift into larger pots in July and grow them on in the frame till October; then move to greenhouse.—E. H.

1920.—Manure for Cucumbers.—Under certain circumstances nearly all kinds of manure may be used for mulching Cucumbers when they require support. For heavy retentive soils I should use horse-droppings that had been dried in a shed for two or three weeks; but for lighter, warmer soils, cow or pig manure is better. Mellow cow manure is an excellent top-dressing for Cucumbers when exhausted from long-bearing.—E. H.

1016.—India Rubber Plant.—India Rubber plants are large rooters and want ample pot space. A plant that sheds its lower leaves shows that it wants more pot room and that its roots are starved. The best course to pursue would be to take off the growing top and plant it as a cutting, which would soon root, and cut back hard the old plant and re-pot it to induce it to break again. —A.

1917.—Plants for Greenhouse.—In a greenhouse where such tenacious things as Geraniums die it is too obvious that the foul air emitted by the paraffin must be destructive to plant life. The arrangement is in fault, and some better heating apparatus should be obtained if tender plants are to be grown. A small gas stove heated from the outside, or a small hot-water boiler, would soon set matters right, and the plants would thrive.

1918.—Window Plants.—Gas need not materially injure plants in a window if air be given during the period combustion is going on, and any ordinary plants may do very well. Just now a window should be gay with Cinerarias, Deutzias, Dielytras, Genistas, Pelargoniums

and may be dressed with one or two hardy Ferns, and a Palm or two, such as Chamærops Fortunei, or Cocos Weddeliana and Draccenas.—A.

1919.—**Soil for the Royal Fern.**—In its native habitat the Royal Fern likes the side of a ditch or stream, where for many seasons leaves have fallen and decayed, thus forming a natural vegetable loam. Good turfy loam, and a large admixture of peat and leaf-soil, should suit the Osmunda well, giving shade and plenty of water in hot seasons.—D.

—— This may be grown in peat, its chief requirements being shade, perfect drainage, and plenty of water; indeed, if the drainage be good, it can hardly have too much water. The finest specimens are those grown upon banks of ponds, &c., where the roots touch the water.—W. S.

1900.—**Cats in Gardens.**—Some years ago I planted some Perilla nankinensis round a border in a garden much frequented by cats, in the centre of which were some choice flowers. In the course of the summer I was surprised to find that that border was carefully avoided by the cats, whilst the flowers in the other borders were almost destroyed by them.—E. B.

—— Respecting cats destroying the Nemophila, I find the very best remedy to be that of sprinkling the beds with Cayenne pepper. I have had cats pay a visit to the bed, and after having smelt it once never return.—R. R.

1934.—**Ferns for Damp Cave.**—I have seen Cystopteris fragilis and Cystopteris dentata growing most luxuriantly where there is a constant drip. I think the Oak Fern would also answer. The Maiden-hair likes such a situation, but I am afraid would be too delicate for the English climate.—A RECTOR'S WIFE.

1917.—**Plants for Greenhouse.**—If the paraffin stove is inside your house I should advise you to have it out at once, as the smell is very offensive to plants, especially those you have mentioned. I have had the same results you mention through having a paraffin stove inside my house. The Musk was a great failure; also some of those you have mentioned; but I was advised by a gardener to have the lamp outside, which I did, at once, and now all is flourishing.—IGNORANT.

1926.—**Green Carpeting Plants.**—Asperula odorata (Sweet Woodruff) will very quickly cover a bare space in any aspect. The foliage now is very compact and a lovely delicate green; next month there will be whorls of deliciously fragrant white waxy flowers; they are a charming mixture with the blue Forget-me-not; a dead white will not do with their blue. In September the plants look untidy, but are most easily pulled even with the ground. The plant runs rampant in sand.—MARK.

1811.—**Brussels Sprouts.**—The best way to obtain fine buttons is to sow in March and transplant first week in May. I intend to sow the seed in September on a warm border, and plant out as early as possible in the spring. If the winter proves tolerably mild they will grow during the next summer 4 ft. or 5 ft. high, if planted 3 ft. to 4 ft. apart and staked to keep them up; manure water benefits them immensely.—A. F. C.

1776.—**Hardy Coleus.**—The name of the Coleus referred to is probably refulgens, and it may be obtained at Messrs. Veitch's, of Chelsea. No Coleus, however, ought to be called hardy.—W. E. LEE.

1987.—**Crested Shield Fern** (Aspidium cristatum).—I have a root of this Fern, but its fronds, when expanded, droop and become flabby. It is in a flower-stand before a sunny-window, in a very warm room (where gas is never burnt); good drainage; soil, leaf-mould. It has been well watered. How can I prevent the fronds drooping, and restore it to its former healthy state?—AUREUS SCARABÆUS. [By giving it plenty of air and keeping it in a cooler place, rather shady than otherwise.]

1988.—**Soap-suds for the Garden.**—Are soap-suds of any use for the garden?—LAURA. [Yes; they may be applied to strong growing crops with advantage.]

1989.—**Guano for Crops.**—How should guano be used for flowers and vegetables?—LAURA. [In a liquid state. If the guano is good, a 3-in. flowerpotful to four gallons of water will be plenty strong enough. If applied frequently, half that strength would be better.]

1990.—**Heat for Cucumber Frame.**—I have a Cucumber frame, the heat of which is declining. Can I still keep the plants going by any heating apparatus other than by manure lining? and can I make the frame of use for anything else during the year? Is it necessary to have bottom heat for Cucumber growing?—A. EVERETT. [If you renew the linings you will get all the heat you require. Bottom heat is necessary for early crops, but not during summer. When the Cucumbers have done bearing you will find plenty of uses for the frame if you read GARDENING weekly.]

1991.—**Watercresses for Sale.**—Is there any work published concerning the growth of Watercresses for sale? If no such work, will some one inform me how I am to lay out beds on about 1½ acres of land, the size, &c., of the beds? I have a piece of land with a small stream running along the top of the land, and having a slope to a river at the bottom, which would take off the water, so that I could keep a constant stream passing over the beds.—C. T. [The system of growing Watercresses for the London markets is given in "Shaw's London Market Gardens," published at our office.]

1992.—**Applying Artificial Manure to Plants.**—How often should Clay's fertiliser be applied to pot plants, also plants in the open ground?—H. T. [A little should be mixed with the soil at potting time, and a little should be applied when the pots are getting full of roots and most want assistance. You must be careful how you use it, as it is very powerful. The best way to apply it is to mix a little with some fine soil, and remove the surface soil from the plants, replacing it with the mixture. Much, however, depends on the kind of plants to be operated on. Arum Lilies, Balsams, Fuchsias, and similar quick-growing plants will take more than plants of less rapid growth.]

1993.—**Heating Stove-house and Conservatory.**—What is the best and at same time the most economical boiler and pipes for the above? also size of pipes and boiler for from 60 ft. to 70 ft.? and what kind of joints to pipes are the best?—DEVONIENSIS. [A fair-sized saddle boiler would probably be the best. The pipes should be 3 in. or 4 in. in diameter. Apply to some respectable horticultural builder.]

1994.—**When to Sow Biennials.**—When should biennials such as Antirrhinums, Wallflowers, Canterbury Bells, Pentstemons, Heartseases, Sweet Williams, be sown, so as to grow sufficiently large to be planted out in the autumn where they are wished to bloom the following spring or summer?—A SUBSCRIBER. [Sow at once in well-drained pans or shallow boxes of sandy soil placed in a frame or in a window, with a sheet of glass over them. Prick out when large enough, and finally plant them where you want them to bloom.]

1995.—**Celeriac.**—Where can I procure the seed of Celeriac, or Turnip-rooted Celery?—A. F. C. [From any good seed house. See our advertising pages.]

1996.—**Treatment of Spiræas.**—Are Spiræas hardy, or do they require some protection? Should they be grown in pots or in the open ground? I believe they require an abundant supply of water; but should the pots stand in water, or be well drained?—F. HODGSON. [If you mean the Spiræa japonica, so much grown for market, which we presume you do, it is best grown in pots. It should have protection, and may by forcing be had in bloom from January onwards. It requires abundance of water, but it is not well to place the pots in water. It is really not a Spiræa; all the Spiræas proper are hardy.]

1997.—**Sowing Dahlias.**—Will Dahlia seed sown this spring produce plants to bear flower this year or next?—CHLOE. [Next year.]

1998.—**Taking up Crocuses, &c.**—I shall be compelled to take up my Crocuses, Tulips, Hyacinths, &c., to make room for bedders. What will be the best way of keeping them through the summer?—C. BAIRD. [Plant them elsewhere in good soil. When the tops have died down, store the bulbs in any dry place, and plant in October.]

1999.—**How to Earth up Crops.**—How can I do this neatly and well.—C. B. [First loosen the soil with a hoe or a fork between the rows; then, standing on one side of the row, draw the soil carefully up to the plants; then turn round and do the other side. When done rake between the rows. You can only learn to earth up neatly by observation and practice.]

2000.—**Greenhouse Plants after Flowering.**—What treatment do Camellias, Azaleas, Heaths, and Cyclamens require that have done blooming? They are in a greenhouse where heat by night is 45° to 50°.—INQUIRER. [You cannot do better than keep the Camellias and Azaleas where they are, picking off all the dead flowers and seed-vessels, and syringing them twice a day till they have made their growth. They may then be placed in a shady situation out-of-doors, or be kept in a shady, airy greenhouse or frame. The Cyclamen should be put into a cold frame, and kept just moist till the leaves have nearly died down, when they may be repotted, removing part of the old soil from the roots. The Heaths should be put in a cool frame or greenhouse where they can have abundance of air night and day. They need not be shaded; as if grown in a sunny, airy place, they will flower better than if shaded.

2001.—**Sowing Primulas.**—When should I sow Primula seeds so as to flower in a greenhouse about December or January?—C. C. [Sow at once.]

2002.—**Narcissi after Flowering.**—May these, after flowering, be kept in same pots for next year's flowering?—J. T. P. P. [If you must keep them in pots we should advise you to re-pot them in rich soil, and place them in a sunny situation, giving them plenty of water.]

2003.—**Climbers for Greenhouse.**—What would be the best climber to cover permanently the inside roof of a lean-to greenhouse, exposed to full sunshine nearly all day. Would a Clematis do, and, without requiring a shade for itself, act as a shade for the greenhouse?—J. T. P. P. [A Clematis would do; so would a Maréchal Niel Rose, some of the Passion flowers, and, in fact, any good greenhouse climber.]

2004.—**Manure-water for General Use.**—How can I make this?—C. B. [Place horse, cow, or sheep manure in a tub or tank, and fill it with water. Then dilute it as you use it, according to its strength.]

2005.—**Hydrangeas.**—I have some Hydrangeas in 5-in. pots; they are showing bloom on the leading shoot. Shall I take the side shoots off or not? and shall I re-pot them in larger pots?—C. J. P. [If the side shoots do not show bloom take them off and use them as cuttings. Give the plants coming into bloom some manure-water twice a week. Do not pot them.]

2006.—**Rhubarb Running to Seed.**—What can I do to prevent my Rhubarb running to seed? The plants were newly planted last year, with plenty of rotten manure under them.—J. G. H. [Your only plan is to pull out the seed-stalks as soon as they appear; they will not be so numerous next year.]

2007.—**Primula denticulata** is a hardy perennial plant. "E. E.'s" description of Veronica Blue Gem corresponds with a flower I have long wanted—an old-fashioned one which in early days, for want of the real name, we called Garden Forget-me-not.—V. F. [Primula denticulata is a hardy perennial, but is best protected during winter. The Veronica Blue Gem is very different from the plant you probably allude to.]

2008.—**Harrison's Musk.**—Is this as hardy as the common variety? and, if it is not, could I keep it through the winter in a cold frame by plunging the pots in coal ashes? The frame is tanked up with turf all round.—HAL. [This Musk is not quite so hardy as the common kind, but would be all right in the frame.]

2009.—**Flower bed.**—I have a little Box-edged flower bed in front of my house that I want to fill with Verbenas this summer. If I sowed some Verbena seeds at once, would they flower this summer? How close ought the Verbenas to be planted together? If I put a row of Portulaca about 6 in. from the Box, and then fill the middle up with Verbenas, will they do together, or will the Verbenas be too high for the Portulaca? The soil of the bed is rather dry and sandy, facing south-west.—HAL. [Verbena seed should have been sown in February; you might try it now. Place it in a warm frame, and plant out rather closely. Portulacas would do well for edgings.]

2010.—**Making a Hot-bed**—*C. B.*—Get a quantity of fresh stable manure with the straw in it, and mix with it a good portion of leaves, if you have them; or short Grass will do. Turn the heap over several times, and if dry, throw plenty of water on it. After a few days the rank steam will be out, when you may make the bed. Mark out a square 3 ft. wider all round than the frame you are going to put on the bed. Then commence to build the manure all round with a fork, always keeping the middle hollow, and treading the whole firmly as the work proceeds. When about 4 ft. high, put on your frame and build all round it till the manure is on a level with the top. Then put in your soil, and in a few days after the bed has settled down you may plant in it what you require.

2011.—**Cineraria Offshoots.**—My Cinerarias have thrown out several offshoots. Should they be taken off when the plants are in flower? or what is the proper time to remove them?—A. V. R. [Let the plants go out of flower; then the off-shoots will gain strength and may be removed.

2012.—**Scale on Apple Trees.**—The Apple trees in my orchard are infested with a blight which covers the entire trunk; it looks like small grey scales, and can only be removed by scraping. What is the name of the blight, and how can I get rid of it?—A LADY. [It is the mussel scale probably. The best cure is that of painting the trees with seal oil after the leaves fall in autumn. Whitewashing the trunks of the trees in winter would do good.]

2013.—**Dielytra spectabilis.**—I have had a magnificent show of Dielytra spectabilis that I bought with other things as a job lot, not knowing what they were (being only roots), and am now anxious to know how to preserve them.—E. C. L. [Divide them if you wish to increase your stock. In any case plant them out, after being duly hardened in rich soil in the open air. Mulch them with rotten manure and give them plenty of water. Pot up in autumn; or you may pot them now and plunge them out-of-doors in ashes.]

2014.—**Growing Chrysanthemums.**—In February I had sent me some small cuttings of Chrysanthemums. I have kept them in a warm window, and they are now growing nicely, some having made good progress, filling the pots with roots; others only now starting. I have but little garden ground; already there are some well-established Chrysanthemums in it which bloomed fairly well last year. I should like to turn the others out if there was a fair chance of their doing well in the open air.—A. M. S. [Put those that are full of roots into larger pots, and when again established you may put them out-of-doors. They would do fairly well in the open garden, but your better plan would be to grow them in pots plunged in the garden till they are coming into flower; then remove them indoors.]

2015.—**Liquid Manure.**—Will you give the proportions of fresh horse manure and water for liquid manure? and will that manure suit Clematis, Wistaria, Passion-flower, Virginian Creeper, Sweet Peas, and Convolvulus? How often should it be given, and in what quantity?—EALING. [Such liquid would suit the plants named; it is, however, difficult to give the proportions. Put a barrowful of horse-droppings into a tub and fill it with water; you can then dilute it as may be necessary. Weak and often will be better than strong and seldom.]

2016.—**Planting Anemones and Ranunculus.**—I have a few Persian Ranunculus and Anemone Hortensi. Should I plant them in the open ground so late as this, or keep them till next year?—L. A. [It would be better to plant them at once than keep them.]

2017.—**Leeks for Exhibition.**—How can I grow a few good Leeks fit for exhibition in July next? I have a box of Leeks which are 3 in. high in a cold frame; could I have them ready in time, and what treatment should they receive?—J. W. [Dig out a trench about 6 in. deep and 9 in. wide. Into the bottom spread 2 in. or 3 in. of rich rotten manure and fork it in. Then plant the Leeks out of the box, 9 in. to 12 in. apart. Apply abundance of water once or twice a week when the plants are growing freely. They should be gradually earthed up with fine soil, in the same way as Celery. You ought to get good Leeks by July next.]

2018.—**Fumigating Vines.**—Is it safe to fumigate a Vinery when the Vines are about to bloom, or are in bloom?—E. T. B. [It would be better to defer, if possible, fumigating till the berries have set, as the smoke will fetch off the bloom prematurely.]

2019—**Sowing Calceolarias and Cinerarias.**—When is the time to sow seeds of herbaceous Calceolarias, Cinerarias, and Primulas, to bloom after Christmas and how?—V. [Sow now in pans of fine sandy soil, placed in a shady frame or greenhouse. Put a sheet of glass over the pans till the seeds are up.]

2020.—**Sweet Peas.**—I have a quantity of Sweet Peas in boxes 3 in. and 4 in. high; I am afraid they are getting spindly. Can I put them out yet with safety, covering them, of course, at night. I keep them out all day, only putting them back in a warm house in the evening. I have so little room with the seeds and plants coming on, that I am afraid I cannot afford space to pinch them out.—G. HARCOURT. [Put them out-of-doors, and protect them slightly at night.]

2021.—**Cyclamens after Flowering.**—How should these be treated?—V. [Place them in a cold frame, giving enough water to keep the soil just moist. When the old leaves have nearly died down and young ones are pushing, re-pot them, in doing which remove about half of the soil from the roots, and pot in the same sized pots, afterwards giving them larger pots if necessary.]

2022.—**Abutilons.**—What heat and treatment do these require?—V. [An ordinary greenhouse or frame; or they will grow out-of-doors in summer. Any good soil will suit them, and in winter a rather dry atmosphere.]

2023.—**Lime Water for Ferns.**—Will lime water to kill worms injure Ferns?—W. S. [No; unless applied very strong.]

2024.—**Raising Seeds.**—Can Cinerarias, Celosias, and Carnations be raised in a cold greenhouse without bottom-heat?—W. S. [Celosias are best raised in heat; the others would grow well in a greenhouse.]

2025.—**Sowing Seed in Pans.**—In sowing seeds ought the soil to be moistened? Ought it to be pressed down or merely levelled previous to sowing the seeds? Should the covering layer of soil be pressed or left loose on the top? Is it well to water at all before the seedlings appear.—Hepatica. [The soil should be pressed moderately firm and be well watered with warm water previous to sowing. The top covering should be slightly pressed to make it level. The less water it is necessary to give before the seeds come up the better, but the soil must be kept moist.]

2026.—**Soap-suds for Pot Plants.**—*F. G. C. P.*—Although soap-suds might in some cases be beneficial to plants in pots, we should certainly not advise you to use them. Pure soft water is much better, and if you want a little liquid manure it is easily made, or there are plenty of artificial manures now sold, excellent for the purpose.

Tulips and Snowdrops not Flowering.—*Learner.*—Bulbs in pots of all kinds have flowered very unsatisfactorily everywhere this year, and probably you had your bulbs potted too late in the season.

Taking up Dahlias and Hollyhocks.—*C. B.*—Dahlias should be taken up when the tops are cut by frost and stored in soil in a box in any dry cellar or loft. Place them in a warm frame or house in spring, and when they have made sufficient growth, take off cuttings if you wish to increase your stock; or part the old tubers and pot them singly, planting them out at the end of May. Hollyhocks can be divided in autumn, and potted and planted out in spring; or they may be left in the ground all the winter, covering their roots with ashes.

Asparagus Kale.—*W. H.*—The true Asparagus Kale is that known as the Milan Kale. Several different kinds are supplied by seedsmen as Asparagus Kale, but the one named is the correct one.]

Hot water.—*J. C. H. P.*—A boiler holding only three quarts of water can not be expected to heat 20 ft. or 30 ft. of piping satisfactorily.

Smilax in Windows.—*Window Box.*—In addition to the article in Gardening, April 3, you will find its culture fully explained in the numbers for July 19th and December 13th of last year.

Labels.—*L. M. S.*—See Gardening, February 7th of this year. If you had sent your address, we could have told you where to get what you want.

H. L.—Your question is one which can only be answered from time to time in Gardening. There has been much information already given on the subject of window gardening.

What is the difference between Scilla præcox and S. siberica? Does the latter succeed the former as to time of blooming?—V. F. [We never could discern any difference either in the appearance of the plants mentioned or their time of blooming.]

Index to Vol 1.—*J. M.*—This may be had of all booksellers, with coloured plate, price 3d.

Title Page for Vol. I.—*E. C. L.*—There is not the least difficulty in obtaining this from our office. We supply title page, complete index, and coloured plate, price 3d.

QUERIES.

Readers are requested to note that every number of Gardening Illustrated *is in print, and may be obtained. Before sending queries it is well to consult the first volume, which contains an immense number of practical articles and questions answered by men well acquainted with the subject.*

2027.—**Acacia in Window.**—Will any readers kindly instruct me as to the management of a small Acacia about 2 ft. high, kept in a 7-in. pot in a south-west window? The leaves are constantly turning yellow, and falling off. I water it two or three times a week according to season; it is planted in a mixture of loam and leaf-mould.—C. J. Bream.

2028.—**Celery for Rheumatism.**—Will the seed of Celery answer this purpose as well as the plant?—T. H.

2029.—**Snails and Slugs.**—I have read with interest the result of "G. W. O.'s" experiments with Little's soluble Phenyle (see p. 65, April 10) as an insecticide or slug-preventive for flowering plants. Will "G. W. O." or any correspondent give their opinion of the use of this liquid as applicable to vegetables, viz., Celery, Cucumbers, Kidney Beans, &c.? My crops are annually half destroyed by the depredations of these troublesome visitors, which defy lime, soot, &c. Also whether this liquid may be safely applied to vegetables without detriment to the consumer, and from whom can the Phenyle be obtained?—G. B., *New Cross.*

2030.—**How to Arrange a Garden with Flowers.**—I shall be going into a house on May 1, and as the garden is 20 ft. by 18 ft., I shall be grateful for information as to arranging it for flowers to look pretty this summer. The mould put into the garden looks good, but rather stony. What flowers or seeds shall I put in? what edging? What designs for beds would be prettiest? Can I get any book to thoroughly instruct me, as I am quite a novice at gardening? I get plenty of sun.—G. J. G.

2031.—**Show and Fancy Dahlias.**—Would some one be so kind as to give the names of the best eighteen varieties of the above for exhibition?—W. H.

2032.—**Carnations, Picotees, and Pinks.**—When is the correct time to sow the above in a cold frame with a little bottom-heat? Any hints regarding sowing of the seeds and after treatment would be esteemed.—W. H.

2033.—**Large Wellingtonia gigantea.**—Can any reader give me the dimensions of the Wellingtonia gigantea that was exhibited at the Crystal Palace some ten or eleven years ago? It was destroyed with the fire that happened there about that time. It came, I believe, from Australia.—Tasmanian.

2034.—**Graveyard Gardens.**—What would be best for a somewhat shady situation, partly under a Yew tree, in a graveyard?—Woodchurch.

2035.—**Ants in Gardens.**—Can any one inform me the best method to get rid of ants in a garden, as my garden is infested with them?—Alpha.

2036.—**Bottom-heat for Frames.**—Will "Petros" kindly explain the undermentioned queries in reference to his article on "Bottom-heat in Frames" in No. 55? 1st. He says "place a (mineral oil) lamp about 2 in. from bottom of boiler." I presume 2 in. from top of chimney is meant? 2nd. He adds "a sun burner 7-8 in. thick is best to use, and large enough." What description of lamp is this? whether for crystal oil or benzoline? what is its capacity, and does he mean that the wick should be 7-8 in. wide instead of thick? 3rd. Is the conical chimney he speaks of glass (as I suppose)? what is its height? and would not the metal one mentioned be sufficient without it? I should be glad of a reply at his earliest opportunity.—F. H. W.

2037.—**Window Boxes.**—Will some one favour me with instructions for making window boxes for plants and seed? And please state if Cocoa-nut fibre mixed with light soil would be suitable for filling same. Can creepers be grown in boxes to avoid a border against the wall of the house which is already damp? and would boxes as for windows be suitable?—Window Gardening.

2038.—**Glazing Without Putty.**—"H. S. H." says he has constructed a greenhouse on the no-putty principle. I should be glad if he would kindly give a few details, as I wish to build one, and should like to adopt the best plan possible. Are such houses suitable for forcing, or only as cool greenhouses?—J. T.

2039.—**Dracæna Leaves Withering.**—Will some one tell me the best method of preventing the leaves of Dracænas turning brown and withering at the ends?—T. W.

2040.—**Gladioli for Succession.**—Will some reader kindly give a list of named Gladioli for early flowering? also a list of late flowering kinds, with their respective colours, &c?—A Learner.

2041.—**Culture of Double Primroses in Pots.**—Will some one tell me how to grow double Primroses in pots in London? I can never get them to live. There is no garden here; the aspect is nearly south. I could put them in a window conservatory among Ferns, but I think it would be too close for them.—Cryptogam.

2042.—**Pansies for Exhibition.**—Being desirous of growing Pansies for exhibition, I should be very glad if any one will give me information how to proceed.—Heartsease.

2043.—**Large Flowering Cactus.**—What treatment should be given to a large scarlet blooming Cactus? It is alive and showing signs of bloom, but some of the leaves appear faded.—J. C. W.

2044.—**Shrubs Under Trees.**—Which are the most suitable shrubs for planting or making a fence under trees? They will be subject to smoke, &c., of passing railway engines; exposed east aspect. I have tried Thorn hedge and evergreens, but without success. What would be the cause?—Zig-zag.

2045.—**Rusty Geranium Leaves.**—Can any one inform me what is the cause and means of prevention of Geranium leaves becoming rusty or spotted?—Fifeshire.

2046.—**Stocks Losing their Leaves.**—I have some stocks in pots which seem healthy and make steady growth, but the lower leaves turn yellow and fall off. What is the cause?—A Learner. [An insufficiency of water or poor soil, probably.]

2047.—**Specimen Blooming Plants.**—Can any one give me the names of one or two plants of easy culture in a town greenhouse to exhibit in a class of specimen plants in bloom in a show about the middle of August?—Exhibitor.

2048.—**Woodlice in Frames.**—Will any reader inform me how to destroy these insects, which infest my frames, and eat off directly they are out of the ground such things as Phloxes, Stocks, &c.? For several seasons I have had entire crops destroyed by them.—C. J. B.

2049.—**Temperature for Ferns and Anthuriums.**—Will some one tell me the lowest temperature (summer and winter) in which I could grow Anthurium Scherzerianum and Adiantum Farleyense?—Arthur.

2050.—**Making a Fern Case.**—Will any reader favour me with hints for the proper construction of an oblong Fern case? It is the bottom of the case that I am in doubt about. I cannot tell how to construct it to get the proper drainage required. Any other information will greatly oblige.—Subscriber.

2051.—**Flowering Shrubs for Front of House.**—I am in want of two flowering shrubs for the front of my house—north-east aspect. Which are the most suitable?—T. M.

2052.—**Rhododendrons.**—I have a bed of good and deep alluvial soil in which I want to grow Rhododendrons. Will some one name me about six good hardy sorts, and the best time to plant?—A. B. G.

2053.—**Climbers for Planting out in Cool Conservatory.**—Which of the following climbers are evergreen, what are their respective colours, to what height will they grow, which ones will do best on the shady side? Also, will any of them do if the roots are planted outside conservatory and protected in winter?—viz.—Passiflora Newmani, Tecoma jasminoides floribunda, Berberidopsis corallina, Stauntonia latifolia, Jasminum gracile variegata, Physianthus albidus, Celastrus scandens.—Hamilton.

2054.—**Hints for Amateurs.**—How truly delicious a garden would be with Mignonette sown broadcast! and I much wish I could succeed in getting it in such profusion into mine. I have the greatest difficulty in getting a few plants to thrive; every year I sow from 6d. to 1s. worth of seed; have tried April, May, and June, and even March. In other plants I am very successful. The seed comes up fairly, and when there are four or six leaves they invariably turn yellow, and finally disappear. My soil is sandy. I should much like to know if any of your other correspondents are equally unlucky with Little Darling.—Mark.

2055.—**Plants for Bleak Exposure.**—My house faces the east, and I have a rockery at the front. Can any one say what will grow in it, as the winds kill everything I put in on the north and east sides, with the exception of King Feather (or London Pride)? Also will some one say if any annuals will flower in my north-east borders?—W. D., *Lancashire.*

2056.—**New Zealand Flax.**—Will some reader kindly give me full details for outdoor culture of the above, whether it is best planted in clumps or otherwise, and what treatment for the winter?—G. Y., *London.*

2057.—**Orange Tree not Flowering.**—Can any one who has had experience tell me if an Orange tree grown from a pippin will ever bear flowers? The tree is seven years old, has good foliage, and is about 3 ft. high. How should it be treated?—Laura.

2058.—**Making Screens.**—I am making a folded screen, covering the framework with black leather, but I cannot make the scraps adhere firmly to the leather with gum; when dry, they are easily removed with the aid of a pen-knife, the whole scrap coming away intact. Can any one tell me what will ensure success in this respect, and whether the screen when complete will be best varnished? if so, with what kind?—A. Everett.

2059.—**Outdoor Winter-blooming Plants.**—Will some reader give the names of a few perfectly hardy plants suitable for a London garden, to bloom in winter or very early in spring; and supply also some information respecting the time that the seeds for such should be sown, together with a few hints relative to their after culture?—J. G. S.

2060.—**Cimicifuga racemosa.**—My plant is alive after the severe winter, and making a weak shoot. Can any one who has grown it successfully tell me the soil and situation it prefers, and whether it requires plenty of moisture?—H. C.

2061.—**Spigelia marylandica.**—My plant, which flowered well last season and seemed healthy, has died during the winter. Does the plant require protection? Does it dislike a calcareous soil mixed with peat? Information from any one who cultivates it successfully will oblige?—H. C.

2062.—**Cottager's Flower Shows.**—A cottager's flower show is to be held in our parish the last week in August. Would any reader who may have had some experience in such things tell me what hardy annuals or other flowers would be suitable to advise the cottagers to grow, either in window-boxes or pots or in very small gardens, and when they should be sown so as to be in bloom at the time named? Also is it advisable to combine a children's flower show with the other, and what would be the probable outlay in a country place, where tents, &c., would have to be hired?—A Yorkshire Curate.

2063.—**Humea elegans Dying.**—Can any one suggest what is the matter with my Humea elegans? I bought six plants from a good nurseryman; they were in 3-in. pots, and I potted them into 6-in. ones. They grew well till last week, when three of them went off all at once. The roots had got to the bottom of the pots. They where potted in leaf-mould, sandy and yellow loam.—An Inquirer.

POULTRY.

Experience in Poultry Keeping.—"A Working Man" on this subject recommends a cross between the Spanish and Dorking fowls as the best sort to keep. Perhaps for laying purposes only they may be; but my experience is that the best fowls are obtained by crossing Brahma hens with Dorkings, and to kill the cockerels and cross the pullets again with Dorkings. By this means a large-bodied and very hardy bird is obtained, with little or no feathers on the leg, which are always an eyesore to the poulterer. The birds, moreover, are excellent layers and good mothers; the eggs, too, ar much richer than the eggs of the Spanish fowle but perhaps not quite so large; and, from having, shorter legs and plumper bodies, the fowls are much better for the table than a bird with Spanish blood in it, whose long dark-coloured legs always look unsightly.—W. T. D.

Gapes in Chickens.—I believe the only safe method of curing this disease is to let the chick inhale the fumes of hot carbolic acid (Calvert's). The best way where only a few chickens have to be operated upon is to put about a tablespoonful of the acid in an empty salad-oil flask (the straw covering being removed); place the flask on its side in a saucer of sand, and apply a spirit lamp under the

saucer, which can be fitted on a wire stand easily made for the purpose. As soon as steam is emitted from the flask, place the chick's head close to the opening, so that it must inhale the fumes; but care should be taken that the operation is not continued too long at one time, as it may otherwise be injurious. In ordinary cases one application is sufficient.—SABINE.

Non-laying Brahmas.—No fowls will lay if fed only on maize. Give them one meal of oatmeal and house scraps, and all the refuse vegetables, and they will soon do their duty. I have for years kept about eight Brahmas in a small enclosure; they only get an occasional run in winter for an hour or two, but I get plenty of eggs (about forty a week now), and from four to six couple for the table during the year, and have never had a sick fowl; but I am most careful about giving variety of food. Every scrap is saved for them in the kitchen, and they are kept most scrupulously clean. I never feed on maize only, but give a mixture of maize, barley, tail-wheat, and buck-wheat.—C. H.

Duck Eggs Failing to Hatch.—I keep seven ducks and two drakes, from which I sat sixty eggs, and every one was rotten; they were kept about a fortnight in an egg closet. What is the reason for this? and is there any means of testing the eggs before sitting?—PINK MAY.

Eggs for Sitting.—Will "Andalusian" say why eggs should be placed with the small end upwards for keeping? I have always understood that to keep them well the large end should be uppermost. The yolk is always nearer to the large than to the small end, and consequently would be likely (I should think) to adhere to the shell and spoil sooner if the small end were placed upwards.—A RECTOR'S WIFE.

Keeping Fowls.—I want to keep, say, half-a-dozen pullets, and a cock bird for eggs (not chickens). I have no yard, and but a small garden, which they would spoil, so must confine them to a run covered in with wire. We have an adjoining place where they could roost. About what size should their run be—length, width, and height, and what for the floor? Are some of the Hamburgh kinds suitable? or are Houdan or any other sorts better? Are the upright sides of the run best of brick, wood, or wire?—HENRY CAMPS.

Fowls Eating Eggs.—I noticed one morning lately a pullet coming away from the poultry house with a considerable portion of an egg, which led me to think all was not right. I found she was eating eggs, a thing which has been taught her ignorantly by giving her the egg-shells to eat.—J. H. A.

Caponizing Fowls.—Can any one inform me where I can get instructions on caponizing fowls?—A CONSTANT READER.

Poultry Breeding.—Can any reader tell me whether chickens hatched from true-bred Dorking eggs by a barn-door fowl, and brought up by the same, away from all other poultry, are in any way injured in their breed, or would injure others hatched by true-bred fowls?—COCK-A-DOODLE-DOO.

Egg Testers.—In last week's issue of GARDENING "Andalusian" informs the readers that eggs may be tested by an egg tester about the eighth day to see whether they are fertile. I think it would have been a benefit to most readers to know what this egg tester is, and should therfore like him to explain; also, whether it would be of any use for eggs which have been set nearly the full time.—A. H. W.

HOME PETS.

Sitting Doves.—I should think "Angie's" sitting doves must be two hens. I never heard of doves laying more than two eggs at a time. They sit for a fortnight. I know of no other way of distinguishing the male dove from the hen except that it is generally larger and coos much louder and more than the hen, which makes a more harsh sound. I shall be very glad to exchange one of my male birds for one of your hens if you are willing.—Mrs. HENRY HENLY, *Calne, Wilts.*

Canary with Rough Plumage.—*Tilly Slowboy.*—A bird out of health will always have rough plumage, no matter what it is suffering from. It is most likely suffering from a cold. Give the hemp a little more frequently, and an occasional sprig of Watercress or other green food.—A. D'A.

Feathers coming off Canaries.—This arises from various causes. Weakness will cause it, or it may be a sort of skin complaint that canaries sometimes suffer from. All you can do is to give it a nourishing diet—not rich, but strengthening; also let it have as much fresh air and sunshine as possible, and an occasional dose of finchine.—A. D'A.

Canary not Singing.—I have a German cock canary which sang beautifully all last year, but will not sing at all now, and has not done so for four or five months; he is not moulting, but looks depressed, and is ill-tempered; eats well; what will make him sing again? I vary his food, and give him green stuff, and put him in a sun-lighted window; what else must I do?—PUSS.

Rearing Hares.—Can any one tell me how to bring up a young hare?—F. M.

Budgerigars.—I have two of these; their noses are blue. Are they males or females? At what time of year do these birds pair?—M. F.

THE HOUSEHOLD.

"THE HYGEIAN COOK-BOOK."*

THIS is a useful little book, based on the principal of cooking all food without salt, pepper, or other condiments. In the preface, Dr. Trall remarks: "For a dozen years past our table for invalids has been prepared without the employment of milk, sugar, salt, yeast, acids, alkalies, grease, or condiments of any kind. Our only seasonings have been fruits and other foods in a normal state, so prepared and combined as to produce the requisite flavour to please without perverting the taste. As our institution stands alone among all the real or pretended health institutions in the world in this respect, we have taken much pains and made many experiments to improve every article and perfect every dish; and we have reason to believe that all persons who desire pure and palatable food, and who wish to 'eat to live,' will find ample directions in this little volume. Among the special advantages of the plan we have adopted, so far as invalids are concerned, is the absence of sour stomach, biliousness, and constipation, so troublesome to all dyspeptics who use milk and sugar. Nor do our patients have any desire to drink at meals. Pure food never occasions thirst; and all physiologists know that taking water with food renders digestion and assimilation imperfect in all persons, and seriously interferes with the recovery of health by invalids." Referring to making sauces, for which there are many recipes given in the book, Dr. Trall remarks: "Persons whose ideas of sauces as dressings or relishes for food are limited to combinations of butter, sugar, salt, vinegar, and spices, may be astonished to learn what varieties of wholesome as well as palatable articles can be made by combinations of fruit and their juices. The number is practically unlimited; but hygienists usually have, or soon acquire, appetites so nearly normal, that they are satisfied with few. All that is required to make wholesome and palatable sauce or dressing is a selection of fruits that are themselves wholesome, and such mixtures and preparations of these as will suit the taste."

Leaf Impressions.—We have received from Mr. Hodson, of Liverpool, a book of leaf impressions, which are so good that we have been induced to obtain from him his *modus operandi*, in the hope that it may be useful to some of our readers. Mr. Hodson says: "After many and careful trials, I found the following to be the best way to success:—On gathering your leaf, mind and not crumple or crack it, and whilst it is fresh place it between two oiled sheets; then place them between any old book-back or pad, and put them under the press; give them a good squeezing, so as to flatten the leaf, and also to take out any extra sap there might be in the veins, because if this is not done the sap might smear your impression. Then take your leaf out and place it between your carbonic paper, which then put between the oiled sheets. (I may add here—let your carbonic sheet be doubled, so that you then get the back and front of the leaf, as I show.) Again place the whole arrangement in your old book or pad and give them a good squeeze. You must then allow a few seconds for the leaf to impregnate itself with the colour from the carbonic paper. After this, take from under the press and lift your leaf from off the carbonic paper very carefully and place it flat in your impression book. Close your book without disturbing the leaf (which will now appear quite black and useless) and give a good squeezing. Take out after about a minute and your impression is complete. Mind and leave your book open for a while, so as to allow the impression to dry; or you may place a clean oiled sheet between the impressions and go on with more without any danger. If you have good-sized carbonic paper and oiled sheets, about that of my book, you will be able to copy five or six ordinary leaves at one time. You must excuse the prolixity of my explanation; however, the *modus operandi* is not so when once you have got in the way; indeed, some of our fellow-readers of GARDENING who can get at an office copying press can do the thing to perfection."

* "The Hygeian Cook-Book; or healthful and palatable food without condiments." By R. J. Trall, M.D. New York: S. R. Wells & Co., 737, Broadway.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 4s to 6s; Azalea, 6s to 12s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 6s to 9s; Lily of the Valley (forced), 6s to 18s; Lilac (forced), 4s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus (paper-white), 6s to 9s; Narcissus (Pheasant's-eye), 6s to 9s; Pelargoniums (zonal), 4s to 9s.; Pelargoniums (large flower), 6s to 12s; Pelargoniums (double), 6s to 12s; Pelargoniums (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 6s to 9s: Violets (blue), 1s to 2s; Violets (Neapolitan), 2s to 4s; Violets (French), 4s to 0s 0d.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s to 6s; Camellias, 1s to 4s; Tra, Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias 4s to 8s; Roses (forced), 1s 6d to 6s.—*Per dozen spray or trusses.*—Bouvardias, 1s 6d to 3s; Euphorbia, 2s to 4s Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 4s to 9s.

Plants in Pots.—*Per doz.*—Arbor-vitæ (golden), 9s to 18s; Arbor-vitæ (common), 6s to 12s; Arum Lilies, 6s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Aralia Sieboldi, 12s to 30s; Ardisia crenulata, 18s to 30s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Berberis, 4s to 9s; Bouvardias, 12s to 18s; Box, 4s to 9s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Clematis, 9s to 18s; Cyclamen, 6s to 18s; Daphne indica, 4s to 9s; Deutzia gracilis, 9s to 18s; Dielytra, 12s to 18s; Dracæna (green-leaved kinds), 12s to 30s; Dracæna 18s to 60s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Hyacinths, 4s to 9s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Narcissus, 9s to 12s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 12s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Scilla sibirica, 9s to 12s; Selaginellas, 3s to 4s; Virginian Creepers, 6s *Per pair.*—Azaleas (large), 20s; Maiden-hair Ferns (large). 5s to 7s; Aucubas (berried), 4s to 6s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 10s to 15s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 20s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pears (fine dessert kinds), per dozen, 9s to 12s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 9d.

Vegetables.—*Per 100.*—Asparagus, 3s to 6s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 9s to 12s; Parsley, 6s; Turnips (outdoor), 3s to 4s; Radishes, 1s 6d to 3s; Herbs, 2d to 6d. *Per dozpunnets.*—Cress, Mustard, or small salad, 2s; Seakale, 36s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s.—*Per bundle.*—Celery, 1s to 4s; Horseradish, 3s to 6s; Salsafy, 6d to 9d.—*Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 9d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel. 2s 6d; Saveys, per score, 8s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 4s to 8s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

THE AMARYLLIS.

THOSE who knew the varieties of Amaryllis in cultivation fifteen years ago, and have seen the magnificent groups exhibited at the Royal Horticultural and Botanic Societies during the past three or four years, cannot have failed to have noticed the striking improvement that has been effected in form, size, and colour. Instead of the small or medium bell-like flowers produced in pairs, with narrow-pointed perianth segments, and varying in colour but little beyond a few not very easily defined shades of scarlet and crimson, we have now robust scapes producing four, six, and even more, grand flowers with broad well-rounded petals, often fully 3 in. wide, forming finely expanded flowers measuring from 7 in. to 9 in. across, with colours varying from rich scarlet and deep crimson to a delicate light rose, and even occasionally to almost white. This great improvement has been brought about by

VEITCH'S NEW RACE OF AMARYLLIS (one-third natural size). 1, Emilia; 2, Ophelia; 3, Malvolio.

several distinct and separate agencies, among the most potent of which may be mentioned the introduction of new species, the hybridisation and inter-crossing of these with the best older varieties, and by assiduous cultivation. It is now some years since the Messrs. Veitch received two remarkable natural species from South America, through their collector, the late Richard Pearce, which have been named respectively Leopoldi and Pardina. By crossing these with the older kinds a progeny was raised showing a remarkable advance over those then in cultivation. The further inter-crossing of this progeny with the species themselves, and with other kinds—such as Ackermanni pulcherrima, and including even the robust Aulica—has resulted in the production of the magnificent race of which our illustration represents three kinds. The Amaryllis must henceforth take a far more prominent place in amateurs' gardens than it has hitherto done; and there is no reason why this should not be so, for the culture is of the easiest kind where a warm greenhouse is available.

The bulbs should be potted early in spring, in a mixture of equal parts of loam and leaf-mould, with the addition of a little animal manure, the ingredients of the compost being thoroughly mixed together. During the growing season water must be freely supplied, and until the flowering is over, and then gradually diminished in quantity till the leaves have died off and the bulbs are at rest. When they have become dormant, stow them away in a dry warm place to rest. After about a three-months' rest, introduce the earlier-ripened ones again to a moist heat, and if they be slightly sprinkled with water now and then all the better; some of them will soon push up flower stems, and when such are distinctly visible let the plants receive a good watering. It is important that the flower-stems clearly show themselves before the plants receive much water, or leaves will be produced at the expense of flowers; in weak plants, if the leaves get the start, the tips of the flower-sheaths just show themselves above the necks of the bulbs, and there remain. Those which flower should have their roots examined as soon as the flowers are off, and if sound and healthy should have a shift into larger pots, using soil as before. It is not well to be in a hurry to separate the offsets which push from the parent bulbs. They make blooming bulbs quite as soon if left undisturbed as if taken off, and a potful of strong bulbs grown together, when in bloom, has a good effect. In examining the clumps of bulbs at the time of re-potting, should any feel loose to the touch divide them and start each bulb separately as at the beginning, using small pots as before, until they have become again established Pots 8 in. or 9 in. in diameter are plenty large enough for Amaryllises intended for ordinary use. As to the time of flowering, Amaryllises may be had nine months out of the twelve by gradually pushing on those that show bloom the earliest and leaving the later-blooming kinds to start without encouragement of any sort.

The following kinds, raised by Messrs. Veitch, are now among the best in commerce, most of them having been awarded certificates by the Floral Committee of the Royal Horticultural Society, and by the Royal Botanic Society:—

Brilliant, a really rich crimson, and beautifully spotted.

Cassandra, bright scarlet, with a rich velvety lustre.

Chelsoni, brilliant fiery crimson.

Crown Prince, broad petals, striped with reddish-crimson on a creamy white ground.

Duke of Connaught, a variety of extra fine form; the most brilliant and deep scarlet yet obtained, which is relieved by a beautiful clear white eye.

Empress of India, a vivid light scarlet, suffused with orange-yellow, relieved by a whitish central stripe.

Junius, deep crimson scarlet. In this variety the white filaments contrast very effectively with the rich colouring of the perianth segments.

Macaulay, rosy red, with white-tipped petals, very distinct.

Maid, a beautiful light variety, dashed with crimson upon a creamy-white ground.

Sultan, deep maroon crimson.

The Baron, deep lake-red, tipped with straw yellow.

Virgil, ground colour delicate French white, the inner portions of the petals spotted and barred with bright scarlet-crimson

To these fine kinds may be added the three shown in our illustration, which are among the most recent novelties.

Double-flowered Ivy-leaved Geranium.—The flowers of this Geranium are perfectly double, and pink in colour, with deep

Double-flowered Ivy-leaved Pelargonium (König Albert).

carmine streaks or veins down the centre of the upper petals. It is named König Albert, and was, we believe, the first double-flowered form obtained in the section to which it belongs. As a decorative plant it is extremely useful, owing to its elegant habit of growth and the profusion with which its flowers are produced by established plants. The Ivy-leaved section of the Geranium family, we need scarcely say, make excellent window plants. For this purpose they are unrivalled, and should always be grown for such purposes, as well as for hanging baskets, for vases, and for the decoration of hollow tree stumps, and for forming beds in the flower garden. All Ivy-leaved kinds are easily propagated by inserting cuttings in a balcony or window-box during the summer months. In the spring they may be struck easily, and cuttings taken off so late as August may be well rooted in the open border before frost sets in, and make pretty little plants for next year's decorations.

Yellow Day Lily (Hemerocallis flava).—For the last three years I have grown this Lily in pots for early forcing, and I must say with very good success. I would, therefore, strongly recommend it for that purpose, its colour being an acquisition and its perfume very sweet. It is, moreover, easily grown, a circumstance which makes it doubly valuable. I had plants of it in bloom all through the spring, and have yet more to flower. They have produced from nine to eleven flower-spikes, and have six and seven blossoms on a spike, forming attractive objects in a conservatory.—J. C.

Potting and Treatment of Camellias.—It is sad to see Camellias in a sickly state. I do not know whether it is owing to the way in which the plants are propagated or to early mismanagement, but it is a fact that vast numbers of plants, especially imported ones, die after they are sent out of the nursery, in spite of all that skill and good management can do for them. There are two periods at which the Camellia may be shifted or repotted. One is to pot the plants as soon as they have made their growth, and before they have matured their flower-buds; and the other is to pot before they have begun to grow, and not when the plants have done flowering. I prefer the first plan, because growth buds are ensured before the plants are meddled with; while, by the second plan, unless the plants are very vigorous, there is a chance of their making feeble growth, not to speak of possible accidents. However, both plans succeed well enough in good hands, or when the shifting of the plants is intelligently performed.

There are fine examples of Camellias to be found growing in pure, or almost pure, loam, which should in all cases form at least the staple of the compost; and perhaps equally good specimens are to be seen in a compost consisting of loam and peat, or loam and leaf-mould, or all three together. As regards the operation of potting or transplanting, it should be performed with great care. It should first be ascertained whether the roots are dry in the centre of the ball—a thing exceedingly likely to occur in the case of old pot-bound Camellias; and, if they are, the whole ball of roots should be immersed in a tub of water, and left to soak for four-and-twenty hours, or longer if necessary. Afterwards the plant should be lifted out, and the ball allowed to drip in some shady corner till it is in a fit condition to operate upon and pot. If the roots are found to be abundant and active at the outside of the ball, they must not be molested much, but the soil may be loosened all over with a blunt peg, just to disentangle the rootlets and induce them to push into the fresh soil. Should, however, the roots be poor and decayed, the soil should be carefully removed until active roots are found in considerable quantity. The plant should then be potted in a smaller pot than before; but I do not consider it advisable to reduce Camellia roots in this way under ordinary circumstances. In potting, the soil should be made tolerably firm under the roots and rammed, not hard, but with moderate firmness, round the sides, taking care to leave plenty of room for watering. In tubs and large pots we leave from 2 in. to 3 in., and in smaller pots seldom less than 1 in. Much depends on this, as we have invariably noticed that the work of watering is much facilitated by providing as much space for water as will soak the roots thoroughly at one watering, instead of at twice or three times. If possible, rain-water should be given to Camellias, and it should at all events be free from lime. Liquid manure may be given, weak and often, to healthy-growing plants that are known to have plenty of healthy roots; but weakly or newly-potted ones are better without it for a time. Under ordinary circumstances the Camellia needs no special treatment, but will grow and thrive well in an ordinary conservatory or greenhouse, or even a window, where the temperature does not often fall below 40° or 46° in winter, nor rise above 80° in summer. The sun's rays should never directly reach the leaves of the plants at any time, but should always be broken by a thin shading of some kind.—W.

Ferns for Covering Walls of Greenhouses.—One of the most easily established plants either on the back walls of greenhouses or on inside rockwork is Asplenium bulbiferum, The young plants form and commence to grow on the mother plant, and if taken off with the portion of the old frond attached to them, and just pegged on to the surface of rockwork, or into the interstices of the brickwork itself, they will soon take root and establish themselves without further care. A. bulbiferum is almost hardy; the individual fronds, too, being of good substance, last a long time in perfection.—J. C. B.

A Blue Primula.—I saw the nearest approach to a blue Chinese Primula I have yet seen the other day in Messrs. Carters' nursery, at Perry Hill, The flowers are really of a bluish lavender colour. The plant is a vigorous grower, and very productive of blossom. A quantity of plants of it in a group were very effective.—S.

Cannas for Indoor Decoration.—I would strongly recommend any person who has not yet done so to procure a packet of Canna seeds and sow at once in pots, in a slight hotbed,

having previously soaked the seeds in hot water for twelve hours, as this hastens the germination. They soon form fine plants for summer and autumn decoration, and their drooping Dracæna-like leaves have a beautiful effect amongst other plants in a greenhouse or in rooms, and will be found very useful and ornamental for halls and staircases.—W. A. G.

Raising Plants from Seed.—For the benefit of those who are desirous of raising plants from seed, but have neither greenhouse nor hotbed, I wish to explain the very simple and successful method I have adopted:—Take a large flower-pot and put Cocoa-nut fibre in it to the depth of 2 in. or 3 in.; then place in it a pot 2 in. smaller in diameter; fill up the space between the two pots with fibre, and soak it with boiling water. Stand the large pot in a saucer; sow the seed in the smaller pot, and cover with a piece of glass. Stand the pots and saucer upon the kitchen range, away from the fire, and the seeds will quickly germinate. When the heat is excessive, as at cooking time, move the pots off the range altogether, and replace when the heat is less. By feeling the outer sides of the large pot it is easy to ascertain when removal is necessary. The fibre must be kept wet. Of course, when the plants are fairly up I cease the stove treatment, and stand the pots in a room looking south, and so gradually harden them off. By this means I have this year raised Begonia Fœbeli and Balsams from seed.—Illawarra.

A Crested Fern.—Few Ferns are more valuable for decorative purposes than Pteris serrulata cristata major. In a small state it is exceedingly pretty, and when grown into a large specimen 3 ft. to 4 ft. through, its beautiful crested pinnæ droop gracefully from arching fronds 2½ ft. to 3 ft. in length. This variety produces spores (seeds) readily, but they seldom produce anything like the parent plant. Division is, therefore, the only sure way of propagating it.—S.

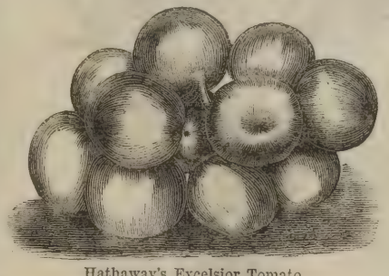
Clematis indivisa.—I observed that a few weeks back some one recommended Clematis indivisa lobata as a conservatory climber, as being free from attacks of insects. My experience of it is the reverse; scale will attack it sooner and increase upon it more rapidly than any other plants I know. It is very pretty for about a fortnight or three weeks; and when the bloom is over the plant is disfigured by the stalks of the blooms, which hang on a long time and require cutting off—a most tedious job. If I had to plant a conservatory with climbers, I would have no plant liable to attacks of insects. One cannot fumigate, as one cannot keep the smoke out of the rooms; and one cannot syringe with insecticides without injuring the bloom of plants underneath or on the other climbers. I should confine my selection to the Lapagerias, red and white, the Tacsonias and the Passifloras, with perhaps a Heliotrope and a Fuchsia. —E. T. B. [We have seen the Passiflora mentioned grown for years without being attacked by insects; whilst we have seen the Lapageria covered with scale from top to bottom. Good culture is the only sure way of warding off insects from greenhouse climbers.]

What can be Done in a Small Garden.—The vegetable portion of my garden is only 55 ft. by 28 ft., in which I have grown, with the exception of last year, sufficient to supply our family of five with one dish all the year round, very often with two, besides herbs, Lettuces, and small salad. We only buy a few Onions and Potatoes, of which we grow enough for one month's consumption. For winter use we have Cabbages, Carrots, Beets, Parsnips, Celery, and Artichokes, all of which failed last year, except the latter and a few Beets. My average outlay for ten years, including manure, gravel, Pea sticks, &c. (but not labour, as I work it myself), has been only 25s.—Hortus.

The Bible Flower Mission.—This mission is started for the purpose of providing patients in hospitals with flowers. Last year no fewer than 260,000 bouquets were distributed amongst the hospitals and infirmaries of London; but this number could be vastly increased were all our readers to contribute a few at times through the year. Any contributions of even the commonest flowers, evergreens, everlastings, &c., would be most thankfully received; and any information will be given by Mrs. L. E. Turton, hon. secretary, 28, St. Martin's Lane, Cannon Street, E.C.

VEGETABLES.

The Tomato, or Love Apple.—Plants for outdoor culture require to be in readiness for planting out by the first week in June—that is, if ripe fruit be expected from them in the open air; if delayed longer, the chances of success are greatly diminished. If the weather be favourable during the latter end of May, a plantation might be made, at the same time reserving sufficient to take their places should they get injured by frost. The exact time at which to sow the seed will of course depend upon the convenience at command for protecting the plants after they are up. If at starting a temperature of 55° or 60° can be given them, the beginning of April will be early enough; but if that amount of warmth cannot be given, and they are obliged to be raised in cold pits, it will be useless to sow before May. Pans are generally used for seed sowing, but if a gentle hotbed can be spared it will be better to sow on that, provided the plants are taken up before transplantation would damage the roots. Perhaps the best method of all is to put two or three seeds in 3-in. pots, and place them near the glass, thinning them out after they are up, so as to leave the best and strongest plant in the pot. After that they should be kept moist, and potted on as they require a shift until the middle of May, when they may be gradually hardened off by putting them into cold frames, and keeping them close for a few days, giving them air more



Hathaway's Excelsior Tomato.

freely as they advance in growth. After they have attained the height of 9 in. or 12 in., the shoots may be stopped, to strengthen the plants and make them more bushy. The growth made after this will be more hardy and shorter-jointed than when the plants were in heat, and they will be more likely to succeed when planted out than if they had not been stopped. A warm situation is indispensable for Tomatoes; therefore if there be one spot in the garden warmer and more exposed to direct sunshine than another, let them have the benefit of it. Vacant spaces between fruit trees on a south or south-east wall are generally the places allotted to them; and where this can be done it is an excellent plan; but the best place for them is a sunny bank, pegging them down close to the ground as growth advances. If a bank be made for the purpose, it should be thrown up high enough at the back to give it rather a steep slope; any kind of rough soil will do for making the bank itself, provided a space be left at its base for suitable soil for the plants to grow in. Ridges similar to those employed for Cucumbers are likewise sometimes used, and with satisfactory results. Another way, and a very good one, is to have rough pieces of trellis-work or hurdles placed in a slanting direction and firmly secured at the front, the back being supported on stout stakes. Plant them at the base, as in the case of banks, and allow the Tomatoes to run over the trellis thinly but regularly; and when a good show of bloom has been produced, pinch off the points of the shoots one joint above the flowers. The fruit will then set quicker and more evenly than it would if allowed to make overgrowth. When sufficient fruit has been set for a good crop, all flowers should be removed, and the shoots should be kept closely pinched in. Thus treated, the fruit will swell rapidly—that is, if the weather be favourable. After planting, a good mulching of rotten manure may be advantageously applied if the weather be dry. As regards size and appearance, Tomatoes have doubtless been improved, but the new varieties are much more tender than the older ones; therefore, for outdoor culture, the latter are to be preferred. The Large Red and Early Smooth Red are the two best varieties for outdoor culture. The Orangefield is a good dwarf, hardy, and prolific variety, and should also be largely grown for outdoor crops. For early crops under glass, or for general crops, where protection is afforded, Hathaway's Excelsior, which we now figure, is perhaps the best variety that can be grown; it is large, round, perfectly smooth, and excellent in flavour, and is valuable for exhibition purposes. It is a kind highly appreciated by American growers, who consider it the best variety in cultivation. Red spider, green fly, and small-winged white fly, are the principal enemies by which Tomatoes are attacked; and these may easily be kept in subjection by means of frequent syringings with Tobacco water. Of late years the Potato disease has attacked Tomato crops just as they are ripening, rendering them useless.

Pea Protector.—I have a Pea protector of my own construction which answers most admirably. I, therefore, desire to describe it. I take two Hazel sticks about as big as my finger—green, and 2 ft. long; then form a bow by bringing the two ends together within 8 in. or 9 in., and sustain them in that position by a string tied across 6 in. or 8 in. from the apex of the bow; then with a knife cut slight notches at 1 in. apart all round the outside of the bow from the said string. I then measure the row of Peas I intend to protect, and thrust the ends of the bow in the ground firmly. I do it at the side of a walk or somewhere to avoid too much treading of the ground where the Peas are sown. Then take a reel of cotton (I think black is best), and, securing the end in the lowest notch in one bow, and holding the reel on a small round stick, run to the other end and fasten it in the corresponding notch, and so on till all the notches are filled. When done it will be a complete arch of parallel lines. It then requires two to take it and place it over the Peas; then a stick thrust down inside close to the bows will keep them from drawing together and keep the cotton tight.—G. T.

Egyptian Turnip-rooted Beet.—This is an excellent variety for shallow soils; its colour is good, it comes into use quicker than the long-rooted kinds, and, having a small top, it can be grown closer together than most sorts, which in small gardens is a great advantage.—W. D.

Mulching Peas.—Covering the soil for a space of 2 ft. or so on each side of the rows of Peas with manure, or half-decayed litter, has at this season an astonishing effect upon both the quantity and quality of their produce; and on dry soils mulching should always be resorted to. —R. A.

Young Winter Carrots.—I find no more useful vegetables during the winter and spring months than young Carrots. I sow them in August outside, on a south border if possible, and commence drawing them in October; and seldom does the bed escape a visit daily. They are used both as a dish, and cut up in so many forms for purposes of decoration, that they have become quite a necessity.—R.

Dwarf French or Kidney Beans.—On a warm south border these may be planted as early as the middle of April; Canadian Wonder and Negro Long-pod are two of the best varieties. Where an early crop is an important consideration, the Newington Wonder, although small, is prolific, and comes in early, but the pods must be gathered when fit for use, as, unlike the larger kinds, they soon get old and tough. Plant in single rows 2 ft. apart, draw the drills with the corner of the hoe from 2 in. to 3 in. deep, and plant the Beans 6 in. apart in the rows. In many gardens they are planted too thickly, and the plants in consequence do not bear so continuously or so freely as they ought to do; and, moreover, this thick planting induces weakly growth, that succumbs sooner to drought or any other unfavourable influences. When fairly above ground draw some of the warm dry surface-soil round the stems to shelter and strengthen them, and gather all Beans as soon as they are fit for use. To secure a plentiful succession, plant a few once a month till the end of June.

Potatoes on Strawberry Beds.—Observing that your excellent correspondent "A. D." intends growing his Potatoes on the above kind of soil, in order to test the relative efficiency of certain artificial manures, I beg to say that I—in common, probably, with many others—shall look forward for the results with much interest. During April, 1878, I dug up and immediately planted, without any manure or previous preparation whatever, a similar bed, 24 ft. by 10 ft., with eighty-one sets of Magnum Bonum Potatoes. In September following I dug up half-a-dozen bushels of excellent tubers, perfectly free from disease, one-third of which averaged nearly a pound each. Last year I obtained somewhat similar results. This season I have planted nearly a quarter of an acre, by way of experiment, with medium and small-sized whole tubers, crown sets and side sets respectively in order to test their relative producing powers under precisely similar and different circumstances.—NORTHANTS.

FRUIT.

GOOSEBERRY TREES THROWING UP SUCKERS.

THIS is often owing to the soil being of such a nature that the plants cannot root deeply without injury. When trees or shrubs root close to the surface, there is always a tendency to throw up suckers. The remedy is to provide the plants with a soil in which they can send their roots deep without meeting anything injurious. Suckers may also be caused by the parts of the plant which are above ground being partly injured and the bark dried up. Any fresh flow of sap from the roots will then have a tendency to rise in suckers. Last winter I had to remove a lot of Gooseberry bushes, which were in a very bad state, all the old wood being covered with Moss and fungus. Some of them had seemingly only produced a few weak shoots since leaving the nursery; these, however, had during last season sent up a dozen or more strong suckers from just under the surface of the soil. The ground is level, and the soil light and shallow, but resting on a stiff marl, through which water passes very slowly, so that the lower part of the soil remains during winter and at any other season in a state of liquid mud.

On removing the bushes I found those which were sending up suckers had been planted so deeply that the original roots were lying in water on the top of the subsoil, and had scarcely thrown out a fresh fibre. A wig of strong fresh roots had, however, sprung from the main stem just under the surface of the soil, from the same point the suckers sprang from. The cause of the suckers was, seemingly, that the plants had been so long in a decrepid state that the vessels were dried up, and unable to carry off the sap made by the fresh roots, which found vent in suckers. A number of Currant trees were in exactly the same condition where planted too deeply. Those bushes which had their roots near the surface were in a better state, but the only one that was really healthy was standing in a drier soil.

Where the subsoil is impervious to moisture, the only permanent remedy is deep cultivation and drainage; but for the present the suckers should be cut away as fast as they appear, a mulching of manure or Grass-mowings applied so as to keep the surface roots moist and cool, and the bushes encouraged to make plenty of new wood and foliage. This treatment will produce a healthy layer of bark and wood by autumn, and if continued for a second year will supply the plants with newly-formed vessels sufficient to carry up all the sap the roots can supply. If the soil is very rich, the plants might be induced to form a second tier of fruiting branches at a higher level than the first by allowing a vertical shoot to rise from the centre and getting horizontal branches from that. Close pruning, thinning, and heavy crops of fruit will always have a tendency to dry up the sap vessels of a plant. With Gooseberries and Currants, which fruit early, a good treatment would be to manure freely as soon as the fruit is gathered, so as to produce vigorous young wood to carry next year's fruit. J. D.

Tuberous-rooted Begonias.—These are becoming popular garden and greenhouse flowers, judging by the immense quantity in preparation at Messrs. Laing's nursery, Forest Hill, where during the summer probably the finest sight of Begonias ever seen will be displayed. A large piece of ground has been prepared in which to plant a variety of the best sorts to show their usefulness for flower-garden decoration. As window or cool greenhouse plants these Begonias are worthy the attention of all amateur gardeners. Small plants grown on now in pots will be ready for planting out in the garden early in June, and will flower in August and September; and when cold nights set in, if the plants are potted and placed indoors they will give a display of bloom till nearly Christmas.

Sisyrinchium grandiflorum.—This elegant hardy perennial is well suited to small gardens. The habit of the plant is well shown in the accompanying illustration. It grows about 1 ft. high, forming an erect tuft of irregularly sized sheathing leaves. The flowers are either solitary or, more generally, produced in pairs, from a two-valved spathe, and are of a splendid dark velvety vinous-purple colour, with yellow anthers. They bloom in April and May. There is a very pleasing variety of this plant with pure white flowers. It is, as yet,

The Spring Satin Flower (Sisyrinchium grandiflorum).

rather scarce, but when it can be obtained it forms an admirable contrast to the purple-flowered type. These plants are quite hardy enough to withstand our ordinary winters. It is, however, safer to grow them in pots, and winter them in a greenhouse or under a frame. The best compost for them consists of a mixture of sandy loam and peat broken into largish lumps. The pots should be well drained and placed in a half-shady position. The plants are very easily multiplied by division of the fibrous-rooted tufts in autumn. It may be had at any good hardy plant nursery.

Primroses for Spring Gardening.—Few plants are more deserving of culture than the many fine varieties of the common Primrose. As they all proceed from the wild Primrose of the hedgerow, they are perfectly hardy, and only require their natural soil, situation, and habits to be imitated as nearly as possible. The double varieties are amongst our finest spring flowers, and may be had in various shades of colour, including white, primrose, golden yellow, lavender, and various shades of rose and crimson. The single varieties are equally fine, and even more profuse bloomers. Country cottagers in the Home Counties are great at Primroses; beautiful beds of them may now be seen in many Kentish villages. I noticed some beds the other morning in a Middlesex village presenting many shades of primrose, rose, crimson, and purple, some of the plants making a very close approach to scarlet, being what is usually described as an orange-crimson. They are not so suitable for spring bedding as some plants, as they do not bloom in perfection unless transplanted in May or June of the previous year; but being neat in effect when out of bloom, and dwarf in habit, two or three lines of them might be used in the front of beds, to form a pleasing contrast with bedding plants, and allowed to remain permanently. Where good single varieties are grown, seed should be saved and sown in leaf-mould as soon ripe, and kept shaded and moist. Many of the plants so procured will be worthless, but some good ones may be expected. Primroses root freely, and require a light rich well-drained soil, containing plenty of vegetable matter in a state of decay. Peat or leaf-mould should be used as manure. The withered leaves should not be removed as they fade, but allowed to decay about the plants. In suburban gardens where the air is still fresh and the houses are not overcrowded, Primroses may be grown with success.—J. D.

Hoteia (Spiræa) japonica in the Hardy Herbaceous Border.—This most popular plant is rarely seen as an occupant of small gardens, presumably from its being commonly offered for sale in a forced, and consequently tender, state; it is, nevertheless, one of the best plants known for a shady border in a rich soil. Strong clumps planted in autumn will flower the following spring. Where forced plants have been purchased they may be planted out when they have done blooming, but will not do much the following season.—J. D.

The Lesser Celandine.—Few native plants are more showy or more likely to yield interesting results under cultivation than this, which would be more prized were it less plentiful. The habit of the plant is neat and compact; the flowers, 1 in. across, are freely produced, and of a good shade of yellow. The plant thrives well in damp town gardens where little else will grow. At one period there were two double varieties in cultivation, double yellow and double white. The leaves are heart-shaped, bright green, and sometimes show a tendency to a variegation similar to that of Cyclamen persicum. The whole plant is glossy, as if varnished.—J. D.

The May Flower (Epigæa repens).—I was surprised and not a little pleased to hear what "Junia" had to say about Epigæa repens, for I delight to overcome difficulties, and I have the plant now in bloom in my garden. I had it from Messrs. Backhouse, York, who doubtless will be able to supply "Junia." It is planted in a peat bed, under the shade of Rhododendrons, and has only had the protection of a few small stones all winter.—HARTSIDE.

Liquid Manure.—As this is the season when amateur gardeners are considering the question of providing liquid food for their "pets," I venture to send a few notes anent my own experiences in this direction, The summer before last my friends and neighbours used to say "How beautiful and healthy your plants look," and certainly they did grow grandly and look well, although the soil of my garden is not a soil, but a dry, hungry sand. As the means I adopted are within the reach of everyone without cost, a few words of explanation will, I trust, prove both interesting and serviceable to the readers of GARDENING. It is no new thing to suggest the use of urine as a liquid fertiliser, but its beneficial effects are only fully realised when it is properly prepared. Fresh urine applied to plants is a mistake. It is only when the nitrogenous matter has become decomposed and turned into ammonia that its value as a manure exhibits itself. To bring about this decomposition in the most rapid and thorough manner is the first consideration. It is a curious fact, and one very well known to our Lancashire fulling millers, that urine will ferment and develop ammonia much more rapidly and perfectly when mixed with water than in its raw state. Hence, to prepare this article for my purpose, I proceed as follows:—Into a pan, tub, or other suitable vessel, I put all the chamber slops (that have had no water put thereto), and other collected urine. To this I add warm rain-water in the proportion of one-fourth, that is, one gallon of water to every three

of urine. When the vessel is full, I allow it to stand exposed to the sun and weather for a fortnight or three weeks, giving it an occasional stir with a stick. Meantime, a second vessel is being prepared to keep up the supply. If the liquid is kept in a warm corner, and well exposed to the sun, it well be ready for use in about a fortnight, but in is none the worse for being double that age. For use, I take from a pint to a quart of the fermented liquor and add it to a bucketful of water, giving my plants a dose three times a week. But in the case of heavy retentive soils I should certainly not exceed the proportion of one pint to a bucket of water, until I had very carefully watched the effects. Where the soil is as sandy as we have it in south-west Lancashire, stronger doses may be used, not only with impunity, but advantage. For vegetables, the stronger dose may be used with safety. My firm belief is that this simple natural fertiliser excels all the patent concoctions. Of course I admit that it is somewhat more troublesome to prepare than taking guano or other portable fertiliser and mixing it with water, and using right off. These latter, however, are not always available, whereas the former is. Moreover, I am a believer in the utilisation of whatever refuse matters are within our reach, without going further afield.—Saxon Deyne.

ROSES.

ROSES FOR NORTH YORKSHIRE.

Hybrid Perpetual Roses.—*White.*—Boule de Neige, Perfection de Blanches. *Light Peach.*—Comtesse de Serenyi, La France. *Salmon Flesh.*—Captain Christy, Madame Devert. *Light Pink.*—Comtesse de Chabrillant, Princess Louise Victoria, Bessie Johnson. *Rose Colour.*—Anna Alexieff, Madame Boll, Princess Mary of Cambridge. *Light Crimson.*—Victor Verdier, Jules Margottin, Glory of Waltham, Camille Bernardin, Comtesse d'Oxford, Marquise de Castellane, Edward Morren, John Hopper. *Full Crimson.*—General Jaqueminot, Maurice Bernardin. *Scarlet, &c.*—Madame Victor Verdier, the Shah, Duke of Edinburgh, Maréchal Vaillant, Sénateur Vaisse. *Darkest Shades.*—Charles Lefebvre, Vicomte Vigier, Jean Liabaud, Duke of Connaught.

Bourbon Roses.—Modèle de Perfection, Armosa, Queen, Souvenir de Malmaison.

China Roses.—Ducher (white), Eugène Beauharnais (amaranth), Mrs. Bosanquet (flesh), Marjolin de Luxembourg (dark crimson), Cramoisie Supérieure (crimson), and Fabvier (scarlet).

Amongst the Bourbons may be planted the two Hybrid Perpetuals, Baroness Rothschild (light pink), and Madame Noman (white). Plant the Hybrid Perpetuals from 5 ft. to 6 ft. apart, the Bourbons from 4 ft. to 5 ft., and the Chinas from 2 ft. to 3 ft. If pot plants can be had they may be planted now; but if not it will be better to wait until October. A good effect would be produced if a few tallish standards of the Noisettes Céline Forestier and Caroline Kuster (yellow), Aimée Vibert (white), and La Biche (cream), were planted amongst the Hybrid Perpetual bushes. These form effective weeping Roses, and, having light coloured foliage, would contrast with the perpetual bushes in every way. No protection would be requisite for any of the above unless the situation is peculiarly exposed. Bush Roses like a rather lighter soil than standards. Gladioli, and such annuals as the Clarkias may be grown between the plants the first year or so, until the bushes attain some size. J. D.

Weeping Roses.—This form of Rose growing on the English Briar is most suitable for Roses naturally of a climbing or rambling habit, and which flower mostly on the ripened shoots of the previous year, requiring little or no pruning, but only an annual cutting away of the old wood which has already flowered. The Briars for the purpose are generally recommended to be planted, trained, and budded where they are to remain. Long clean-stemmed Briars of extra length can only be looked for in strong soils and where the roots have the help of the drainage of a farmyard. In such situations stocks may be found even 12 ft. or 14 ft. high; there is nothing impossible, therefore, in raising such exceptional Briars artificially. Standards of suitable varieties can be had from the leading Rose nurseries up to 8 ft. high. Of summer flowering Roses, suitable families are the Austrian Briars, the Boursaults, some of the Hybrid Chinas, the Ayrshires, and, for very sheltered situations in the south of England, the Multifloras. For conspicuous positions the best Roses for the purpose are the evergreen Roses, and the Noisettes, and hybrids of Noisettes and Teas; both these classes flower best with the shoots bent down, both flower mostly in clusters or bunches. As the finest of all, take Maréchal Niel, and imagine it like a Weeping Ash covered with flowers. The shoots have to be trained something in the form of a frame or hoop.—J. D.

THE LACE-WING, OR GOLDEN-EYE.

The lace-wing or golden-eye (Chrysopa perla), here figured, is not a garden destroyer, but a destroyer of garden destroyers. It is the great destroyer of green fly; hence all gardeners will look upon it with respect. Its aspect (that is, the aspect of the perfect insect) is by no means suggestive of destruction; a more delicate, beautiful, and ethereal creature cannot well be imagined. The species are pale greenish, or yellowish, or almost white. The wings are like a film of lace, the body "as thin of substance as the air," and its eyes large, prominent, and like polished golden globes glittering in the sun.

A Gardener's Friend: the Lace-wing, or Golden-eye (Chrysopa perla).

Although called a fly, it is not truly what is ordinarily meant by that word, It is not a two-winged fly like the house-fly, but belongs to the same order as the dragon-flies, and forms one of the genera constituting the family Hemerobidiiæ. There are about a dozen of species of Chrysopa found in Britain, of which the commonest is the one of which we now speak.

They are common about hedges, gardens, fields, plantations, &c.; in fact, wherever they prey the green fly is to be found. They fly principally by night, and are sluggish and easily caught by day. Although so lovely, they are in one respect like a whited sepulchre: they have a bad smell. They are common in June, July, and August, in which months the eggs are deposited in a very remarkable fashion. The reader will see in the woodcut something like an aigrette, a few hairs, surmounted each by a knob, standing out all round. These knobs are the eggs, and they stand upon a fine elastic flexible hair-like stem. It is not difficult to conjecture how they are thus laid. There must be glutinous liquid near the ovipositor which envelops the egg, and does not immediately part from it when the female places it on the leaf or object on which she is laying. As she withdraws her abdomen from the spot, the egg does not readily quit it, but the gluey matter is drawn out like a thread of sealing-wax, and when it parts the egg is left standing on the top of it. The length of this hair of glue varies; it is sometimes as long as an inch, at other times shorter. These eggs are thus very curious-looking objects; and we well remember how puzzled we were when we saw them for the first time. It was on a Cherry, where several were standing, and, like others before us, we were at first disposed to take them for some sort of vegetable production—a fungus, or the capsule or seed-vessels of some Moss. It is unnecessary to say that this contrivance is a very effectual protection from enemies, the elasticity and tenuity of the hair or stalk giving no hold to any creature that might attempt to lay hold of it. The eggs are often laid in clusters, as here represented, but as frequently one by one at little distances from each other. It is the larvæ that are the real enemies of the green-fly—the perfect insect apparently eating little or nothing. But the larvæ make up for it. They are called by the French *lions des pucerons*, or green-fly lions. They vary considerably in colour, being brown or whitish with orange spots, and having sixteen fleshy tubercles down the sides, but they are difficult to detect unless when engaged in the actual occupation of seizing and devouring their prey. They cover themselves with a coat of many colours, composed of portions of the green and delicate lichens which cover old trees or palings, or of the skins of the green-fly that they have sucked dry, so that unless when they are in motion it is not possible either for the prying eye of the entomologist, or the still quicker eye of the titmouse and other small birds to detect them; and thus disguised they lie in wait with patience for their prey. When amongst them, however, their sluggishness vanishes; they seize them with their long and powerful jaws, and will devour the largest of them in half a minute, leaving nothing but the skin. They are exceedingly voracious, and will clear a whole leaf from green fly in an incredibly short time. After feeding in this way for about a fortnight, they go into the chrysalis state, first spinning a small whitish cocoon, which they attach to the leaves of the plants, and about which the pieces of lichen and skins of flies that formed the covering for the larvæ usually stick; but the remarkable thing is that this silken cocoon is spun, not from the mouth of the insect, but from its tail, as is done by the spider. It would seem that it must be spun from the same reservoir of glutinous matter which supplies the hairs on which the eggs stand, and seems opposed to the view entertained by Curtis and other entomologists that this reservoir is in the ovaries. The cocoons are very small—so small that it is a matter of surprise how the long wings of the insect could ever have been folded up in them—often not bigger than a Barleycorn or small Pea. In this they change to the pupa, and in the summer time they come out in the perfect state in about three weeks; but those that pass into the pupa in autumn remain in it until spring.

Freeing Walks from Weeds.—During May these will require particular attention in regard to weeding, the old method of hand-picking being yet the best. The objections to this system are the amount of time taken up in the work, the impossibility of pulling up the very small weeds which show themselves after the first shower, the loose surface left should there be many weeds, and that hand-weeding does not destroy any seeds which may exist in the gravel. Corrosive acids have been recommended for clearing weeds from walks, and also salt; but these, although effective, if used of sufficient strength and in sufficient quantity, can only be applied with great care, as any vegetation in the shape of edgings with which they may come into contact will be sure to suffer more or less. Acids are also destructive to watering-pots, clothes, &c., and they will be found expensive, whilst salt is unsightly, as, to be effective, it should lie on the surface for some time, its effect when used with water in a boiling state being less satisfactory than when used in a dry condi-

tion. It must also be remembered that whether acids or salt are used the weeds remain for some time in a withered condition on the surface. Generally, when roads and walks are made with a view to utility, the work of weeding is trifling; but if broad roads and walks little used exist, they are certain to become extremely troublesome in this respect. Sulphuric acid (vitriol) is perhaps the most efficacious for the purpose of killing vegetation, and it should be diluted with twenty, thirty, or forty times its volume, according to and in proportion to its concentration. Salt used in a dry state may be put on at the rate of from 2 lb. to 4 lb. per square yard with boiling water. It matters very little the quantity used, provided it be not less than that recommended in a dry state. The action of both acids and salt is not permanent, but may, if well done, last the summer and autumn. The best time for applying them is during dry weather, as weeds are then in a state to take up the maximum of the poison applied. Hand-picking should be done in moist weather, the weeds coming up better when the paths are in a soft state; and if well rolled, the effect is more easily obliterated.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 3.—Sowing Dwarf Green Curled Savoys, and the following sorts of Broccoli — Walcheren, Autumn Self-protecting, Carter's Champion, Wilcove Late White, Cattell's Eclipse, and Leamington; potting on Cockscombs, Celosias, young Cyclamens, and Duetzia gracilis; hoeing up all weeds and suckers amongst Raspberries, leaving six canes to a root for training; digging out a trench and getting it filled with fermenting material, and otherwise getting it ready for ridge Cucumbers and Vegetable Marrows; potting scarlet, pink, and white Pelargoniums; shifting seedling Petunias into 6-in. pots; sowing Centaureas, Coreopsis, Jacobæs, and Celosias; also Marjoram and Basil, and more Scarlet Runners; plating Celery with Lettuces on the ridges; staking Tree Carnations and placing them in the open air in a sunny situation; putting in cuttings of scarlet Pelargoniums and Panicum variegatum; watering Radish, Mustard and Cress, and other seed-beds; hoeing among all growing crops.

May 4.—Sowing the following sorts of Peas:—Giant Emerald Marrow, Dr. McLean, Ne Plus Ultra, and Omega; also two rows of Johnson's Wonderful Longpod Bean; giving all Broccoli, Turnip, and other seeds a dusting with wood-ashes early in the morning to keep down the fly; digging all flower borders ready for planting; turning over gravel walks in back shrubberies to give them a fresh appearance; looking over all Strawberries that are well set, picking off the weak and late blossoms, and tying up Lettuces to blanch; potting double-flowered Wallflowers, scented-leaved Pelargoniums, and Duetzia gracilis; also Ridge Cucumbers; sowing pots of Mignonette and beds of Chervil; planting Vegetable Marrows and pricking off a frame of Stocks; dibbling in Beet seed where plants have failed to come up regularly; putting Balsams in intermediate pits; thinning Turnips; stopping the shoots of Broad Beans as fast as they come into flower; staking Collinsias and other annuals intended to flower in pots; earthing-up spring-planted Cabbages and Cauliflowers; hoeing among Rose trees, Raspberries, Carrots, Parsnips, and Peas; sticking Peas as they require it; washing Camellias and syringing Peaches and Nectarines with soft soap and Tobacco-water to kill aphides.

May 5.—Sowing Primulas, Cinerarias, Stocks, Asters, and Humea elegans; potting on Chrysanthemums and Azaleas; leaving on air night and day in early Vinery in which the Grapes are colouring; clearing early Potato frames, and getting them ready for Melons; digging out more Celery trenches, and getting the manure into them. Sowing Rhodanthe Manglesi and another crop of Spinach; pricking out East Lothian Stocks in frames, and Lettuce plants in beds out-of-doors; putting in Coleus and Scutellaria cuttings; tying Carnations and staking Delphiniums; placing Camellias at one end of greenhouse and putting shade over them; earthing-up Broad Beans; putting all spare hand-lights over French Beans in border; filling up blanks and watering Cauliflower plantation; also watering Turnips and mulching Strawberry beds with short straw to keep the fruit clean.

May 6.—Sowing Leeks and Mustard and Cress; potting Balsams and spring-struck Fuchsias; stopping all young shoots on Fig trees; staking and tying out old Fuchsias for exhibition; planting out three trenches of Red and White Celery to come in about the middle of August; hoeing amongst Strawberries, and cutting up chaff from litter as it comes from the stable for mulching them; looking over peach trees on walls, picking off all curled leaves, and disbudding them where required; potting Capsicums, Tomatoes, and Cucumbers; also Globe Amarantus and Petunias; sowing another crop of Turnips, Lettuces, and French Beans; staking Heliotrope and Mignonette in pots; preparing land for Scarlet Runners; weeding and cleaning Asparagus beds.

May 7.—Potting a batch of young Vines; also Melon plants; staking and tying up Mignonette in pots; planting French Beans in cold pit previously brought forward in pots; thinning Turnips, Carrots, and Spinach; renovating all linings round frames; potting Heliotropes in 4½-in pots for summer blooming; potting off Tuberoses, Marjoram, and Sweet Basil; also young Cyclamens; sowing another batch of Balsams, Mignonette, Mustard and Cress, and Chervil; putting in cuttings of Iresines, Justicias, Thyrsacanthus, Panicum, and Fuchsias; clipping hedges; weeding Violet beds; thinning Turnips; raking land ready for sowing Peas and Beans; watering Cauliflowers, and top-dressing Liliums; earthing up Broad Beans; hoeing Strawberry plantations previous to mulching them with short litter; manuring and digging land for planting Savoys.

May 8.—Looking over Peach house, and tying in all young shoots; also Cucumbers and Melons; picking off all false blossoms, and stopping them where required; hoeing amongst all growing crops; sticking Peas and getting them earthed up; potting off spring-struck scented Verbenas; shifting scarlet Pelargoniums, Stocks, and Anemone japonica into large pots; sowing White Stone Turnips; making ridges ready for planting Vegetable Marrows; manuring Celery trenches; sticking Peas and Scarlet Runners; thinning Carrots and Turnips; clearing Watercress beds of weeds; cutting down remainder of old Fuchsias, and placing them in Peach-house to start into growth; watering seed-beds with weak guano-water.

Glasshouses.

Azaleas done flowering remove from the conservatory to a warm pit or a warm corner of the greenhouse, where they can be daily syringed and assisted to make their growth. Camellias, Acacias, Myrtles, Araucarias, and similar plants planted in beds and borders in greenhouses, should now be growing freely, and consequently require extra attention in the way of watering. Pot on plants of double Petunia, using light sandy loam and well-decayed manure for the purpose. Mimuluses in conservatories are very ornamental; and, used in that way, a strong, rich, moist soil and cool position suits them best. Lemon-scented Verbenas also make good conservatory plants, as do likewise well-grown Heliotropes.

Cinerarias and Primulas.—A little more Cineraria seed should now be sown to succeed the earliest batch; also Primula seed to furnish plants in bloom for the winter. Those who have not had much experience in raising Primulas from seed frequently find a difficulty with them, as the seeds are very tender, and must only be very slightly covered. A good method is, after filling the seed-pans with finely sifted soil, consisting of three-fourths loam and one of leaf-mould mixed with a little sand, and making the surface firm, to sow the seeds evenly, not using any covering of soil, but laying over the top a little chopped Sphagnum Moss; a sheet of glass placed on the top will keep the soil sufficiently moist to cause the seed to vegetate. As soon as growth has commenced, the Moss must be removed, otherwise the young plants will become lanky and weak; gradually expose them to the light.

Flower Garden.

Phloxes, Pyrethrums, Pentstemons, &c., in Pots.—These hardy border plants may be classed together for convenience sake. Their culture is much the same; they require good rich loam and 8-in. or 9-in. pots, well drained, for plants with four or five stems. The flowering-stems are now well advanced and the pots are filled with roots; if there is any lack of vigour give manure water weak at every alternate watering. Support the stems with suitable sticks. This class of plants requires a considerable supply of water at the roots, and they suffer if that be neglected even for a day; they show signs of distress by the oldest leaves becoming yellow and the stems hard and wiry. They should all be out of doors now, sheltered if possible from the north-west wind.

Polyanthuses.—These are much more lasting than Auriculas; the centre truss comes up first, and small trusses are produced for a few weeks afterwards; therefore the same plant will remain in flower, if kept in a cool place and shaded from the sun, for at least six weeks. The leaves under glass have a tendency to become drawn; it is better to remove the lights altogether in fine weather and admit air at night. Water freely and remove all decaying blooms; as they go out of flower place the plants on a cool bottom out-of-doors for a time.

Chrysanthemums.—A cold frame, up to the time when the plants have got fairly established in 5-in. or 6-in. pots, with plenty of air, and fully exposed to the light, is the most suitable place for these. If cuttings were put in in November or December, and kept in a cool place just out of the reach of frost, they will ere this have been transferred to pots of the size just named. Such as were propagated later through the winter must, as soon as the little pots they occupied are filled with roots, be at once moved into larger ones, stopping the shoots of those that are intended to be grown in the usual bushy form; but a portion may be grown in the shape of standards on a single stem from 2 ft. to 2½ ft. in height, and not stopped until they have reached this, after which, nip out the points two or three times, so as to induce them to break a sufficient number of shoots to form the head, and all on from the first, removing any side breaks below these or sucker growths from the bottom; but for growing in this way the freest flowering medium-sized kinds should be selected, as many of the largest bloomed varieties that are not able to perfect so many flowers are not so well adapted for this shape. Mrs. Rundle, white, incurved; Mrs. Dixon, rich yellow, incurved; George Glenny, straw coloured, incurved; Julie Lagravère, velvety crimson; Hermione, blush; Annie Salter, yellow; Lady Talfourd, rosy-lilac; purpureum elegans, violet-crimson; and others of similar habit, will all be found suitable for growing in the form of standards.

Carnations and Picotees.—Plants in beds and borders are now starting into growth, and will not succeed if neglected. Make them firm round the roots by pressing down the soil with the fingers; and, if necessary, a short stick should be placed to any weakly subjects. See that the surface of the beds is stirred up and that weeds are removed while they are in a small state. By this time the earliest-rooted plants of the perpetual-flowering section ought to have been potted off; and on the care taken of them now depends whether they will gladden the cultivator with their beautiful sweet-smelling flowers at Christmas or not. The plants should be encouraged with a little warmth during cold weather, but they must be placed near the glass, and where a free circulation of air can be admitted amongst them. Pot off others as they require it, using small pots. Seeds of the different sections may also be sown in pots, placing them in a hotbed.

Hardy Primulas.—The most useful at present are P. amœna and its varieties—hardy kinds enough, but they do not stand well out-of-doors, owing to damp and frost. In cold frames they stand severe frost with impunity. We leave the plants in cold frames until the flowers open, when they are removed to the greenhouse. Primula japonica sometimes flowers well in pots, and, although this variety has not quite realised the expectations formed of it, still it should be grown for the sake of variety. Green fly persistently attacks it, and also red spider, pests which must be destroyed. In short, all this class of plants grow and flower freely in cold frames, and should be removed to the greenhouse when in flower.

Fruit Garden.

Orchard House Fruit Trees.—In orchard houses in which no artificial heat is employed the temperature must be ruled by the weather. It is advisable, therefore, on bright sunny days to close the lights early in the afternoon, to secure a higher temperature for the night. Disbudding and pinching all strong shoots, and thinning the fruit where set too thickly, will be the routine for this month. Insects must be diligently looked after. Green fly and red spider may be eradicated by fumigation or syringing with Tobacco water or with Quassia-chip water.

Cucumbers and Melons.—A steady bottom heat will still want keeping up, and by attention to syringing and a moist atmosphere the foliage will appear clean and healthy. The fruits on both Melon and Cucumber plants often set too many at a time, and require thinning, so as not to weaken the plants too much. Put pieces of slate or glass under Melons grown in frames, to prevent the damp soil from rotting the young fruit. When Melons are grown in pits, and the plants trained on wires or trellises, the fruit when getting heavy must be supported on a square piece of wood with a piece of string fastened to each corner tied to the wires, leaving plenty of room for the fruit to swell to their full size. Cucumber and Melon plants in frames will still want covering up with mats at night, and continued till all danger from cold weather is over.

Kitchen Garden.

It is by strict attention to the smallest details that success is to be attained; therefore, beginning with the seedlings, these should always be thinned before there is the slightest danger of disturbing the roots of those that are to remain. Many crops are irretrievably injured by neglect in regard to thinning them at the proper

time. Onions, Carrots, Parsnips, Turnips, and kindred subjects, should all be thinned out as soon as they are large enough to handle, and afterwards the ground between the rows should be deeply stirred. The main crops of Beetroot, Broccoli, and Kale should now be sown. Broccoli requires light deep soil, free from rank manure, its best fertiliser being soot or a surface-dressing of guano as soon as the seed is sown. For heavy tenacious soils, burnt earth, charcoal, and wood ashes are preferable. French and Runner Beans may now be sown in quantity. Amongst the different sorts the best for a main crop is the Canadian Wonder; if sown thinly in rows, 30 in. apart, it will require small Birch twigs to support it, as, under good culture, it is a prodigious cropper. As a Runner Bean, Giant White bears to the very bottom of the haulm, and continues bearing throughout the season, if well mulched or watered in dry weather. Cauliflower plants that were wintered in hand-lights require high feeding, and, should the weather turn out to be dry, a dose of liquid manure will be of great assistance to them. Plant out successional batches, and also spring-sown Cabbages and Coleworts, which will come in for early autumn use. Brussels Sprouts are a most important crop, for amongst all the winter greens these have this winter proved to be about the hardiest. The main crop should now be planted; 3 ft. row from row, and 2 ft. plant from plant is none too much. Thin out the seedlings of any that were sown in rows for a permanency. This is the best system of culture, its only drawback being that ground cannot at all times be spared to thus sow them. Main crop Peas must now be sown in quantity, in doing which it is well to forestall the weather, and sow them in trenches, in order that in the event of drought supervening they can be well watered, as these, like Cauliflowers, are thirsty subjects, and resent dryness by the production of mildew instead of Peas. Earth up and stake advancing crops, and if an extra early dish be desired pinch out the tops; the lateral growths will soon show blossom, but, of course, this is at the sacrifice of produce. Asparagus should now be looked over every morning, in order that all heads may be cut before there is the least trace of the buds at the tips of the shoots opening. Plots of ground that have been occupied with winter greens will now be becoming vacant, and should be dug or trenched, according to the crop intended to be sown or planted on them. If for Celery, simply clear off the stumps, and dig out and manure the trenches; and if time and labour be scarce, the same mode of culture will answer for Peas, but preference should be given to entire trenching, when time and labour admit of it. A constant succession of small salads must be kept up by frequent sowings in the open air. Tomatoes, Capsicums, Ridge Cucumbers, and Vegetable Marrows should be potted ere the roots get entangled together, and be grown on sturdily till the last week of this month, when they may be transplanted to their fruiting positions, either near south walls, on south borders, or in other sunny sheltered spots. Prick out Celery, Cauliflower, and herb seedlings, and grow them on, with partial protection as long as cold winds and frosts continue.

Pot Marjoram, Sweet Marjoram, Thyme, and Sage should now be sown on ground previously well prepared for them by fine raking, as owing to the seeds being so small they would be lost if the surface was rough; after raking, smooth the surface with the back of the spade, then sow the seeds and cover lightly with sifted soil. A little Beet may now be sown for an early supply, but do not yet sow the principal crop, as it is liable to run to seed if sown early. Sow in ridges 15 in. apart; where the soil is shallow it may be drawn into ridges about 6 in. high, and on these sow the seed, four or six together, in shallow holes 1 ft. apart, covering them not more than ½ in. deep. A little more Cabbage seed should also be sown, using on this occasion the small-growing Cocoanut, a kind which comes to maturity quicker than the larger varieties; these will form good heads for use all through the autumn, planted on ground on which the first Potatoes and other early crops have been grown. One of the principal things to be observed in a well-managed kitchen garden is to always have in readiness something to plant in the places of such crops as have just been cleared off. Keep the hoe going wherever it can be used when the weather is dry.

Leptosiphon roseus.—To produce the best results with this charming annual, it must be strongly grown, and robust specimens can only be obtained by thin sowing. In light dry soils early autumn sowing is strongly recommended. It is not enough to sow the seed at any period of autumn, it must be—and this applies to most annuals sown at this season—committed to the soil sufficiently early to permit the young plants to attain some size before the setting in of winter; in short, a good framework must be laid, which, on the return of spring, will develop into an effective tuft, covered with multitudes of elegant rosy-carmine flowers, both reflecting credit upon and delighting the heart of its cultivator. When the sowing of the seed has been deferred till a late period of the summer, it is better to sow in boxes or pans in a frame or orchard-house, and plant out seedlings in April; or, in case this should be thought to involve too much trouble, the sowing may be deferred till early spring. A fair amount of success may be looked for, especially in good soils, in which spring sowing will often yield excellent results; the advantages of autumnal sowing are, in fact, best seen in the light sandy soils which suffer so much in seasons of drought. In the accompanying engraving the habit and profuseness of bloom of this exquisite little annual are well represented, and it needs but a slight effort of the imagination to guess the results which might be produced by combination of similar tufts in the formation of beds or borders. All the species of this genus, or rather section of the genus Gilia, are thoroughly deserving of universal cultivation. The very pretty L. luteus and its deeper-coloured variety aureus, are scarcely inferior to the L. roseus, which they

Leptosiphon roseus (a hardy garden Annual).

closely resemble in their general habit, but have somewhat smaller flowers. The hybrid varieties of these, introduced by Messrs. Vilmorin-Andrieux & Co., of Paris, are no less interesting for their supposed origin than for the singular variety of shades occurring amongst them. Of both species there are good white varieties, which deserve special recommendation, that of L. densiflorus being particularly desirable.—W. T.

SMALL SUBURBAN GARDENS.

It is very difficult to get a satisfactory effect out of the narrow slips of garden usually attached to semi-detached villas and terrace houses in the neighbourhood of towns. If shrubs and trees are planted to hide the fences, the circulation of air is impeded, and, especially if the houses are high, the ground becomes sour, breeds Moss and fungus, and refuses to grow many plants that would otherwise thrive.

A bare style of garden becomes almost a necessity if flowering plants are to be grown, but there is no valid objection to a few trees at one end or both ends, so long as the greater part of the ground is not shaded in any way, or sheltered too much from the prevailing winds. The best way of hiding the fences in such gardens is to cover them with creepers or climbing shrubs: Cydonia japonica, Cotoneasters, and Ivies for shady or easterly aspects, and Jasmines, Passion-flowers, and Virginian Creepers, or fruit trees, on sunny walls. A very frequent mistake in gardens of this sort is to lay down Grass in the centre, surrounded by a continuous walk, and a narrow border of flowers close under the side fences. The centre of the garden is the best place for flowers, and many things will grow there which will not do in the side borders. If the length of the ground lies east and west, there will be a shady side which gets no sun in winter and very little in summer. This may be planted with Periwinkles (Vinca Major and Minor), Lily of the Valley, Scillas, Hoteia japonica, and Pansies raised from seed in spring.

In gardens running east and west it is not well to attempt a symmetrical arrangement of plants or beds. If a single walk is made near the south side, the remainder can be arranged for a display of hardy herbaceous plants, with front lines of spring flowers, annuals, or bedding plants, or a mixture of all three; or a piece of turf may be laid down, with small beds next the walk and a continuous border under the sunny fence. If the length of the garden is north and south, a symmetrical arrangement will be more successful; but even then the border facing east will not suit plants which require plenty of sunshine so well as the other side. In selecting plants the time that can be devoted to gardening should be well considered. Beginners, in the first flush of enthusiasm, are apt to attempt too much; and that which is at first a pleasure becomes a task, and at last a burden. A thoroughly good soil, not too stiff, is the first consideration; and that provided, a good stock of hardy things which will almost take care of themselves should be purchased. Those who can only give a glance at their gardens morning and evening, except on Saturday, should avoid all difficult subjects, and fill their beds and borders with plants which only require to be properly planted in the first instance to be all right for a year at least, with the help of an occasional watering in dry weather. For a beginner who has everything to learn, it is not a bad plan to lay out a garden as a school, by running a straight walk down the centre, and laying out the ground in small beds, 3 ft. or 4 ft. wide, at right angles to the centre walk. If only one kind of plant is grown in each bed, the requirements of each can be studied separately. One bed may be Stocks, another Pansies, a third Sweet Williams, a fourth Zinnias, and so on; and if the general effect is rustic, a fine display of cut flowers can always be had, without injury to the effect of beds in which no general effect is attempted.

It is a great mistake to keep continually digging and chopping the soil amongst plants. Many things root near the surface, and if these roots are cut, the year's growth is injured. Beds and borders should not be tidied up in the autumn to make them look clean and smart in the winter; decaying stems should be cleared away, but the litter of withered leaves should be allowed to remain on herbaceous borders, when it protects the plants from frost, and nourishes them for the returning spring. A great deal can be done in small gardens with annual climbers trained up trellises and poles. Even the best varieties of the common scarlet Runner Bean are not to be despised as decorative plants; Sweet Peas and major Convolvulus do well in good soils; and the climbing Tropæolums in poor ones. A semi-circular screen of trellis-work covered with climbers make a good finish to a small narrow strip of garden when the back of the house faces the north, as all the flowers turn their faces to the south. Such a screen will serve to hide a vegetable garden, or the indispensable heaps of manure, frames, beds for propagating, &c. Amateurs whose time is limited should avoid bedding plants, except those which can be purchased cheaply every spring. A few Geraniums can be kept in the windows of the living rooms during winter and planted out in summer; but any attempt to preserve a stock of tender plants without proper appliances and plenty of time to attend to them, will almost certainly result in failure. Cuttings of Geraniums can be struck in the open ground during the summer; these will make nice plants by the following season, if kept rather dry, and just safe from frost during the winter.

Many hardy plants can be multiplied by cuttings exactly in the same way; and those which refuse to strike in the open ground will do so in pots or pans under bell-glasses, or with the simple help of deep boxes covered with sheets of window glass. Where a small hotbed and a cold frame or unheated greenhouse are available, a good display of Asters, Zinnias, and annual Phloxes may be made in beds and borders with very little trouble. These are very suitable for small gardens, and require very little attention when properly planted beyond picking of the faded flowers. In the matter of edgings, ornamental tiles have a neat effect, but have a tendency to harbour vermin. Dwarf Box looks

well with old-fashioned plants, but precludes the use of very dwarf plants close to it. Grass verges are very neat and pleasing but take up a lot of time in keeping them in order. Perhaps the best of all edgings is the common Thrift, but, being a rock plant, it requires peculiar treatment, or it becomes irregular. Where it is used the beds must not be raised or sloped to the edging, and the walks must be very porous, so that there is no accumulation of moisture where they touch the beds; and must not be raised in the centre to throw the rainfall to the edgings. The plants must be set almost in the walks, so that at least half of the cushions of leaves they form rests on the gravel. The plant may be found growing wild on the sea-beach, just out of the reach of high tide. A Thrift edging, with a line of Double Daisies next it, forms a very neat finish to small beds or narrow borders.

Where time is limited, it is well to keep all plants which have to be moved, such as spring bulbs and bedding plants, within comfortable reach from the walks, so that the beds have not to be trodden on in attending to them. The back portions of borders and centres of beds can easily be filled with plants requiring only very occasional attention. By this arrangement much may be done by utilising occasional scraps of time in planting out and picking off past flowers without change of dress. When the best annuals are used, as they should be in all suburban gardens, a great point is to have a good supply of pots of various sizes in which to bring on successional sowings of plants to take the place of those which have done blooming. A little practice enables the cultivator to have nice bushy plants ready to plant when wanted; and if these are in pots the old plants can be removed, and the new ones substituted quickly, and with very little check to the plants. In a small garden a great improvement on the ordinary bedding system can be effected by simply ringing the changes on the many fine varieties of annuals, biennials, and perennials, which can be easily raised from seed, growing only a few varieties each year. For example, in August of the present year sow beds of Pansies, Sweet Williams, and Campanula Medium Calycanthema, and prick them out when large enough where they are to flower the following season. In spring raise Ten-week Stocks. With the help of a few annuals and Tom Thumb King Nasturtiums, these will, with a stock of permanent plants, make a garden for one season. Next season take Delphiniums and Foxgloves sown in autumn, and Asters and Zinnias sown in spring. The third season take autumn-sown Stocks and Indian and Japanese Pinks, and Phlox Drummondi; the fourth season Pinks and Carnations sown the previous year, and so on. The best of the perennials may be retained as permanent bedding plants and propagated.

No suburban garden in the south of England should be without a good stock of Chrysanthemums. They make a fine show on the very verge of winter, and are easily grown if suitable varieties for outdoor cultivation are selected. The cheaper kinds of Gladioli also should on no account be omitted from the most circumscribed list, especially if the soil is light and well drained. A beautiful centre line for a flower-bed would be alternating clumps of Gladioli, English and Spanish Irises, and white Lilies, all of which like the same light rich soil. It is not advisable to attempt the cultivation of Roses in the suburbs of large towns, except in parts where the prevailing winds blow the smoke and exhausted air in a different direction. If the air is comparatively pure, the old white Rose may be tried with success; also the Maiden's Blush, and the common Damask or Monthly Rose, as bushes on their own roots. If these succeed, some of the very vigorous Hybrid Perpetuals may be tried in the same form. Standards should be avoided.

Vases of flowers, statuary, fountains, and all kinds of artificial ornaments, are particularly suitable for small gardens, and agree well with the evidently artificial boundaries and confined space. Some of the best arrangements of small gardens may be likened to conservatories without roofs, and stocked with hardy plants instead of tender ones. For a thoroughly town garden perhaps the best arrangement possible would be to run a line of beds 4 ft. or 5 ft. wide down the centre of the garden, alternating with one or more terra-cotta vases in the same line; these beds to contain no earth, but 2 ft. deep of Cocoa-nut fibre refuse. A few small beds of earth might be left close to the walls, in which might be grown Vines and Ivies to cover the walls, White Jasmine to form an arbour, and German Iris and Orange Lilies as permanent plants; between these beds semi-circular wire or ornamental wooden stands for pots might be placed against the walls. The whole stock of flowers except the plants named would of course be pot plants plunged in the vases and stands, and in the Cocoa-nut fibre beds. The walks might be either asphalte or ornamental tiles. Such a garden would be expensive, but would be far better than struggling to grow in beds of earth plants which would gradually dwindle away. Many things might be grown on the roof or in the windows of the upper floors, where there was more air and sunshine, and transferred to the garden when in bloom; and if a small greenhouse is available, and the air which passes into it is filtered through cotton wool during winter a respectable list of plants may be grown on the premises. It is during cold weather that many town plants suffer through the resinous coating which protects the dormant buds of many of them becoming encrusted with soot and dirt; during summer the evil influence of smoke is much lessened. Pot plants are much more easily and handily managed and kept clean in a town than plants in beds, and in case of an outbreak of vermin they can be much more easily washed or fumigated. J. D.

A Greenhouse Annual (Schizanthus papilonaceus).

Schizanthus papilonaceus. — This beautiful annual makes a really splendid pot plant, growing about 2 ft. high, and bearing flowers very much resembling butterflies with outstretched wings, the petals being blotched and spotted much in the same manner those insects are marked. Seed should be sown at once in a moist heat. The plants should be pricked out when large enough, placing four or five round the sides of a 6-in. pot. In this way, if rich soil be used, excellent plants may be had in flower in July and August.

House and Window Gardening.

CULTURE OF PLANTS IN WINDOWS.

THERE is no branch of gardening which embraces such a wide range as that relating to the culture and preservation in a healthy state of plants in dwelling-houses. There are and always will be so many who have no frame or greenhouse, that the question of how to grow plants successfully in windows is necessarily of the greatest interest to them. Those who have even the convenience of a cold frame will, of course, find the task of decorating the dwelling much facilitated; but, as I have said, there is unhappily a great portion of our population who not only are not provided with this simple accommodation, but whose garden is of the most fragmentary character. This is more especially the case in large towns, where windows in many parts form almost the whole available space in which garden operations are conducted. There is, however, no reason for any one to despair of attaining success, for I have noticed that it is more from want of knowledge than from adverse circumstances that failures occur.

Choice of Subjects for Cultivation.

Formerly the choice of plants suitable for culture in rooms was somewhat restricted, Cactuses and various other kinds of succulents being mainly relied upon for that purpose. Now, thanks to the exertions of plant collectors and to the improvements which have been effected in many of our florists' flowers, we have an abundance of subjects from which to choose. It is almost impossible to give a list of plants suitable for every one, as the conditions of air, light, warmth, and atmospheric humidity vary according to the situation and uses to which the rooms are put. For instance, a plant that would do perfectly well in an apartment that is not constantly occupied, where ventilation is somewhat freely given and where artificial heat is seldom applied, will linger and die where a fire is constantly kept and oil or gas is freely burnt. On the other hand, we shall find certain plants that can only be kept in health by placing them where they are screened from draught, and where the air is maintained at a certain temperature. The care which these two classes of plants will require will necessarily be of an entirely different description, and it is just in this respect that the plant grower in windows will have to exercise judgment. As an illustration let us take the Cyclamen, a beautiful window plant, but one which will only succeed in a cool room; confinement is certain death to it. An india-rubber plant, on the contrary, will thrive best if kept tolerably close, but it must receive certain attentions which the Cyclamen will not need. It will thus be seen how widely varied the treatment of room plants must be, and how necessary it will be to choose suitable subjects for each situation. Then, again, we must take the aspect of each window into consideration. A Moss or a Fern will thrive admirably where a Fuchsia or a Pelargonium will give but little satisfaction. In most dwellings there are windows having different aspects; all that is necessary, therefore, is to ascertain in which of them the desired plant will best thrive. The various types of vegetation, flowering and fine-foliaged plants, &c., may be all represented, and the grower will thus be enabled to secure a series of plants — pictures, as it were, each one presenting distinct characteristics of its own. Whilst indicating a few of the plants best adapted for window gardening, I would advise that growers should allow some scope to their individual likings, and make trial of those plants which they may have a fancy for. There is much yet to be accomplished in this branch of gardening, and the pleasure and honour derived will be in proportion to the difficulties surmounted. There are many plants now considered difficult of culture which probably only require to be better understood to render them amenable to room culture. For a confined atmosphere, such as an ordinary sitting-room, we must rely chiefly upon fine-foliaged plants, those possessing leaves of a somewhat hard, leathery nature being the easiest to preserve in health. Ficus elastica and Cooperi, Aspidistra lurida and its variegated form, Dracæna terminalis, congesta, and indivisa, Cordyline rubra, Chamærops excelsa, Livistonia borbonica, Corypha australis, Maiden-hair and other Ferns, are amongst the best for such situations. For apartments that are but occasionally heated, Grevillea robusta, Acacia lophantha, Aspidistras, Chamærops excelsa, Aralia trifoliata and reticulata, Cyclamens, Solanums, Primula sinensis and denticulata, Violets, Mignonette, Tropæolum tricolorum, and bulbs of all kinds may be grown. The plants enumerated are all suitable for winter and early spring. In summer we get a much greater variety. Pelargoniums, Fuchsias, Lobelias, Petunias, and all the various kinds of bedding plants will grow and bloom admirably in windows during the summer season. A very effective and gratifying display can be made by sowing different kinds of annuals in boxes made to fit and affixed to the outside of the window. Nasturtiums, Sweet Peas, Esch-

scholtzias, Mignonette, Phlox Drummondi, and such free-growing persistent-blooming plants, when thus grown make a dwelling very pleasant to the eye. This method of floral decoration is not nearly so much adopted as it should be; the cost of a box or two and the necessary fittings, as well as the small amount of seed required to sow them, is very trifling, the cultural care, too, being of the simplest. Windows facing the north and east are most suitable for boxes, inasmuch as they there get only the morning and afternoon sun; and, being shielded from the fierce noonday heat, the flowers last longer in perfection. For a northern aspect there is no more beautiful plant than the common Moneywort; when well grown it forms a drapery of lustrous green and bright yellow, such as is scarcely equalled by any other plant. In windows facing the north nothing will give more satisfaction than Ferns and Mosses, which, at all times lovely, acquire additional luxuriance and beauty in just those very places where most other plants refuse to flourish. Any of the following may be selected, they being all of fairly easy culture:—Asplenium bulbiferum, Adiantum Capillus-Veneris and cuneatum, Pteris cretica and scaberula, Onychium japonicum, Davallia Novæ-Zealandiæ, Niphotolus Lingua, and Selaginella denticulata. Succulent plants should not be omitted, as they afford variety, give but little trouble, and are really interesting; they must, however, be grown where they get the full heat of the sun. Many of the old-fashioned plants, such as the Candle-plant and the Partridge-breasted Aloe, are now but seldom seen. They are, however, very distinct in manner of growth, and deserve a little more attention than they now get. Vallota purpurea is a handsome, evergreen, bulbous-flowering plant which any one may grow. Campanula Barrelieri is a pretty little trailing plant suitable for a small basket. I once saw a beautifully flowered specimen of it hanging on the outside of a window in a crowded part of London. Saxifraga sarmentosa and Cactus flabelliformis may be both employed in the same way—the one in a shady situation, the other in the full sun. The plants above enumerated may all be cultivated and kept in health in the dwelling-house. There are, of course, a great number which may be introduced for a time into apartments but which cannot be retained therein without injury; but of these it is not my intention to treat. The owner of a glasshouse will, of course, not need to grow these plants in the windows of his residence.—J. B. C.

The Night-scented Stock.—Amongst night-flowering and night-scented plants this is one of the best. Its flowers, being of a dull colour, would probably be passed by unnoticed were it not for the delicious perfume which they emit as soon as the sun goes down, and which claim for them a place in balcony and window gardens, where their value is soon recognised. Plants with either scented leaves or flowers are great favourites here, but the prevailing fashion of adorning gardens as if sight were the only sense to be appealed to has driven out of cultivation many plants that once were held in high esteem; their unobtrusive hues would be lost amongst the glaring clouds of scarlet Geraniums and similar showy plants, whilst the foliage of many does not adapt them for the sub-tropical department. In balcony and window-boxes and borders, however, such plants are at home, and their fragrance is always welcome as it steals through the open window on the morning breeze or in the calm of a summer's evening. The Heliotrope, Stock, Balm of Gilead, Mignonette, Musk, Aloysia citriodora, and scented-leaf Geraniums are all thoroughly adapted for purposes such as these. It strikes freely by means of cuttings, or may be raised from seed, and only requires the protection of a cold house or pit in winter. It will succeed in any good light soil, and will flower in great abundance with a small amount of attention.—J. G. H.

Birds and Peas.—Place wooden pegs at each corner of the bed; also two pegs in the middle of the bed, one on each side of the row; stretch white cotton from corner to corner, so as to form diagonals; recross to half-length pegs. The birds do not touch my Peas treated this way.—R. K.

HARDY FERNS IN GARDENS.

In most gardens there are situations which, owing to perpetual shade through buildings or trees, are found extremely difficult to embellish satisfactorily. Places of this description occur frequently in the neighbourhood of the dwelling-house, and are often a source of vexation, as the majority of flowering and fine-foliaged plants will not thrive therein. For such localities hardy Ferns are the most suitable occupants, inasmuch as the self-same conditions which prove so fatal to the well-being of the majority of ornamental plants are just those which enable them to maintain themselves in health and luxuriance. The construction of a Fernery is often supposed to entail a considerable amount of labour and expense, and it is this consideration which deters many from undertaking the culture of hardy Ferns. The Fern tribe is a large and varied one, and if it is desired to cultivate a large variety, then, undoubtedly, a good amount of forethought and care will be necessary to ensure success. There is, however, a considerably large class which is really hardy in every sense of the word, inasmuch as they will thrive in almost any situation, and require but an ordinary amount of care to be taken in planting. And amongst these are fortunately to be found great variety and exquisite beauty; they are, therefore, all that can be desired for our purpose. Many varieties of Lastrea, Asplenium, Scolopendrium, and Polypodium will

Cave for the Killarney Fern in Yorkshire.

flourish in the most ordinary garden soil, and can hardly be excelled in elegance of form and diversity of growth by the more tender kinds. They may be easily procured at a cheap rate of any nurseryman, and some of them, such as the common Polypody, the male and Lady Fern, are to be found plentifully in moist hedgerows, from whence they may be safely removed in early spring before growth commences. These varieties are mostly strong growers; they should therefore, be so planted that they are not stinted in the way of nourishment. Ferneries upon a small scale are apt to dry up in hot weather, and the occupants fail to obtain that luxuriance which constitutes one of the greatest charms of the Fern tribe. Although something in the way of burrs, stumps, or sandstone is necessary to keep the soil open, yet this kind of material should be introduced in the present instance merely to effect that purpose, leaving as great a bulk of mould as is consistent with good drainage. The cheapest material that can be employed is the root stumps of trees. In country districts hedges are being grubbed up occasionally, and a good cartload may be purchased for a few shillings. Those living in the neighbourhood of populous towns could arrange with some friend in a rural district to consign a load to them as an opportunity might occur of procuring them. They are admirably adapted for the purpose, and not only serve to efficiently drain the soil in which they are placed, but appear to retain in themselves a certain amount of moisture, even in very dry weather. Root stumps are often objected to on the ground that they ultimately rot away. That is, however, no detriment in the present case, as by the time they do so, the plants are well established, will have filled the soil full of fibre, and be eager to feed upon the decaying matter which is thus presented to them. As to soil, there is no necessity to be at all particular. If some turfy loam or rough peat can be easily procured, they will be benefited by an admixture of it. Ordinary garden soil, with some of the roughly-sifted portion of the refuse-heap, will meet their requirements. No garden can be considered properly furnished without Ferns of some sort, and many a dark dingy corner may be simply and almost inexpensively beautified by them. Where winter verdure is desired, the evergreen kinds need only be employed. In a general way, however, they should be used with the deciduous ones, as they contrast so beautifully when bursting into growth in spring.

J. C.

The Killarney Fern.—So many notes and questions have appeared in Gardening in respect to this Fern, that we give the accompanying illustration from Robinson's "Alpine Flowers," to show that it may be grown successfully without the aid of glass. The illustration shows the entrance to Mr. Backhouse's cave for growing this plant. It is in a deep recess, perfectly sheltered and surrounded by high rocks and banks clothed with vegetation. Here in the darkness grows the Killarney Fern, Hart's-tongue, and other hardy kinds, guarding the entrance. It is likely that various kinds of New Zealand Trichomanes and Filmy Ferns will prove as hardy as the Killarney Fern, and, if so, this is likely to be one of the most attractive and interesting of all phases of outdoor gardening.

Birds in Gardens.—Those who recommend the indiscriminate destruction of small birds can never have taken the trouble to study the habits of the different species that inhabit our island—a difference, so far as the gardener is concerned, that is not always determinable by the individual species of birds, for some will attack particular crops in one part of the kingdom that escape injury in others. There is also a difference in the stage of growth in which a particular crop may be when it is attacked by some species of birds in different localities. Sparrows, for instance, in some parts of the country begin their work of destruction upon Peas the moment they appear above ground, nipping the points of the shoots; but if kept from them until the Peas get fairly above ground, no further molestation will be experienced until the crop is ready for gathering. In other places they never cease their attacks from the time the Peas are up until they are removed from the ground. In my garden they keep at them all through the season, nipping out the leading points, and as soon as the flowers are formed picking them out from the leaves with which they are enclosed; and if means were not taken to prevent them we should never have a Pea to gather. In the Cheshire market gardens and in the neighbourhood of Manchester they will frequently make an attack on the Onion crop as soon as it appears above ground, pulling the young plants up, simply through, to all appearance, a disposition to do mischief, for they leave the young plant, seed and all, lying on the ground entire, while in no other part of the country have I seen them molest Onions. My winter Lettuces are often attacked about the beginning of March, and if not made unpalatable by a dressing of soot they destroy the whole crop. Crocuses they never allow to open, as they attack the flowers as soon as they show colour, pulling the petals to pieces so as to get at the pollen, for which they seem to have a particular liking. Gooseberry and Currant buds suffer as much in this neighbourhood from sparrows as they do in some localities from bullfinches. Cotton, such as is used for dip-candle wicks, ravelled out singly, and strung loosely so as to be moved by the wind over anything they molest, I have always found sufficient to scare them off; even after the Peas are sticked I find it necessary to use this. Chaffinches and greenfinches take indiscriminately the seeds of all the Cabbage family. At one time I used netting to protect these seeds until they were sufficiently large to be out of danger; but it is a troublesome job,

as nothing you can do will deter them, and if there is a possibility of getting under the net, or through it, you generally have the mortification of seeing your young crop destroyed. I have, for a good many years, coated the whole of the seeds of this description with red lead, and never since have I lost a crop. I have heard, however, that some who have tried this have found it to be ineffectual; but I suspect the lead was not properly applied. The seed should be damped, but not made too wet, and thoroughly coated with dry powdered lead, which should be allowed to dry on before the seed is sown, when it will stick so fast that if any of the seed lies on the surface of the ground the rain will not wash it off. The house sparrow and the finches are all but an unmixed evil in gardens; all the small soft-billed birds should be encouraged as much as possible; the larger species—blackbirds and thrushes—notwithstanding the quantities of snails and other pests they destroy, require to be kept within reasonable limits, or the production of fruit, where it is required in quantities, without incurring expense in nets and other protecting material equal to the value of the fruit, is an impossibility. Those who advocate the protection of all small birds forget that kestrels, merlins, sparrow-hawks, jays, and magpies—Nature's instruments for maintaining the wanted balance in the smaller feathered tribes—are all but exterminated; hence the necessity for reasonable reduction in their numbers by other means.—B. A., *Middlesex*.

ANSWERS TO QUERIES.

1962.—**To Make a Garden Pay.**—That a garden of the size mentioned can and does in some hands realise a profit is certain; but the willingness to work hard must be blended with forethought and knowledge of the requirements of a neighbourhood. I know a man that has occupied all his life since he grew up to manhood a garden of about an acre, and from that acre of land he has produced enough to bring up a family of four children; but his Radishes, of which he grew vast numbers, were always first in the market, as were also his Lettuces and ridge Cucumbers, Vegetable Marrows, &c. To have crops coming on when there is little or no demand for them cannot yield a profit; and mixing up the supply of a private family with market gardening is also a drawback, as things have to be grown in dribblets to produce a succession. The market gardener only aims at getting his crops ready when they make the best price.—E. H.

1955.—**Rats in a Country House.**—I live in a country house, and when I first came here rats and mice were a serious nuisance. I, however, got rid of the lot in time. I tried several rat poisons without effect; ultimately I procured some paste from a chemist (I withhold his name for fear it may be looked upon as "touting" for him, although I shall have pleasure in giving it). I spread it on some bread and butter, cut it in squares, and laid it in the runs. Next morning I found dead rats in all directions. Nevertheless, there is a serious objection to poisoning rats, as the bodies rot and become very offensive. I therefore procured a little Scotch terrier, a thorough good ratter, and an additional cat. Since then I have not seen a rat nearer the house than the piggery.—RUSTIC.

1895.—**Green Garden Pots.**—To clean garden pots as good as new, get 1 quart of hydrochloric acid and mix with about 14 gallons of water in a wooden or earthenware vessel, and lay the pots in for six hours or more; then rub them with a piece of rough cloth. Wash well in clean water and leave them to dry. I have done about 300 pots, and find this plan answers admirably; I have also recommended it to my friends, who are much pleased with the result. The pots are fit for use as soon as dry. The price of the acid is 1s. for 8 lb., which will clean about 2 gross of pots of various sizes.—T. BROWN.

1986.—**Watercresses.**—These may be grown by turning the overflow water from a well along a channel or over a bed of any size or shape planted with roots or cuttings of Watercresses in spring, when they are plentiful. The bed may be excavated 1 ft. or so deep, some good soil placed in the bottom, made firm, the cuttings dibbled in, and the water permitted to flow gently in on one side, and make its exit at the opposite one. Watercresses may easily be grown by planting cuttings in a shady border, and keeping them moist; or they may be grown under hand-lights anywhere, shading during sunshine; they be also be successfully grown in pans or pots in the greenhouse or window; and a succession may be kept up throughout the year as easily as Mustard and Cress.—E. H.

2030.—**How to Arrange a Garden with Flowers.**—The prettiest designs for beds are circles, or ovals, or figures in which curved lines predominate. There is no book that will thoroughly teach gardening or any other business. Books are aids, and often remove a stumbling block from our path; but reading and experience should go hand in hand. It is too late now to think of spring flowers, but there is yet time to sow Sweet Peas, which may be done in circular patches. Gladiolas may yet be planted; mark the place with a short stick to prevent injury being done to the young growths. For centres and backgrounds, Hollyhocks, Tritomas, tall Phloxes, and Delphiniums may yet be planted; and for late autumn display, Rudbeckias, Japanese Anemones (white and red), Sedum spectablis, and Michaelmas Daisies will give freshness and beauty amid the falling leaves. All kinds of annual and other flowers may be sown now thinly in patches; amongst others may be named Candytufts (red, white, and purple), Clarkia pulchella, Nemophilla insignis, Collinsia bicolor, Calliopsis coronata, Virginian Stocks, German Ten-week Stocks, German Asters, Sweet Williams, Snapdragons, &c. For edgings the Golden Feather is bright and pleasing; Sedum glaucum makes a neat grey edging, Cerastium tomentosum a good white, and Dell's Crimson Beet, sown now, not a bad dark crimson for those who are not prejudiced against vegetables among the flowers, and the roots are good for use in winter if stored before frost comes. Lay the ground out as simply as possible, avoiding intricate figures; place a good-sized circle in the centre, a good path of turf or gravel round it; and a border round the outside would be a good arrangement, and give easy access to every part.—H.

1964.—**Making a Lawn.**—"Alpha" will find several articles on this subject in GARDENING ILLUSTRATED, Vol. I. If good turf cannot be got, get good seed. The ground should be dug a uniform depth, and made quite level by trampling first and rolling afterwards; then rake the surface, removing all coarse stones; sow the seed thickly; cover with some fine soil, and roll it in firmly. If sparrows are plentiful near the ground you had better put them some food at night, so that they can breakfast without your Grass seed.—RUSTIC.

1838.—**Ants on Lawns.**—I have always found that camphor water will drive ants away. It can be made by putting an ounce or two of camphor in a stone bottle holding about a gallon of water; let it stand for three or four days, pour off, and use. If the camphor is not all dissolved, the bottle can be refilled, as the water will only absorb a certain quantity. Should the ants be indoors, or anywhere else that water cannot be used, dry camphor laid about their haunts will answer the same purpose.—H. W.

1975.—**Parsley for Exhibition.**—Parsley if sown in a hotbed frame or a moderately warm house in February will by the first week in April be fully 1 in. high. The plants should then be potted off singly into 3-in. pots, and grown on in them for a month, gradually hardening them off. Plant out early in May in a good bed or border about 18 in. apart; shade a little till established, after which they will begin to grow vigorously. Water liberally with weak liquid manure, say once a week, but withhold it the week previous to the show. The day before the plants are required for exhibition, lift them with a large ball of earth; have an 8-in. or 9-in. pot at hand, and when you have reduced the ball sufficiently, allow it to drop into the pot. If this be in the month of September, you may consider you have a good plant if the outside leaves project 3 in. over the pot all round, and it is finely curled; but remember curl is the point more than size. If "John Brown" is required to have only one plant in a pot, by following these directions he ought to succeed; but use a pot in proportion to the size of plant at the time.—ECOSSAIS.

1960.—**Culture of Sunflowers.**—Sow the seed at once in gentle heat; harden the plants in due course, and pot them into good soil in clumps of three or more, about 6 in. apart, surrounding each plant closely with peat charcoal dust if you can get it, to prevent the ravages of the slugs; they are partial to young Sunflowers. Procure your seed from a good house, and ask for the double kind; the single ones are not worth growing. There is not the slightest difficulty in cultivating this plant. If you keep poultry, the birds will eat and enjoy a few of the seeds occasionally.—RUSTIC.

1963.—**House Slops as Liquid Manure.**—I am a strong advocate for the use of peat charcoal, and, having recommended it in several of my contributions, I may here perhaps answer "J. T.'s" inquiry and that of "Victis" at the same time. Some months ago I had several bags of charcoal left at my place by mere chance, and having heard much respecting its value for many purposes, I resolved to try it. I put it under my horses' beds to absorb the moisture, and then put it into a tub (half-full) to receive house slops, in the pigsties, &c. It keeps the stable sweet; it prevents any unpleasants mell from the house slops; and afterwards, so far as I can see, makes a valuable manure. I have used it in many ways with my crops this season, and shall be able to write more fully upon its merits in a few months' time. I may, however, say this with confidence—slugs do not like it; therefore I use it freely when transplanting Lettuce or other favourite food of these pests. It has this advantage over soot or lime—it does not injure the most delicate plant by contact. I am unable to say where peat charcoal can be obtained at present; but I am given to understand that large works are being erected at Dartmoor for the purpose of making it; so that in a short time, if all be true I have heard about it, it will become a valuable article of commerce, obtainable in London or elsewhere.—RUSTIC.

1952.—**Slugs in Greenhouses.**—Try some air-slaked lime—that is, lime which has fallen to a powder by exposure to the air. Sprinkle this about over night where infested with slugs. Remove in the morning. Repeat the operation, and you will soon be quit of the unwelcome visitors.—SAXON DEYNE.

1973.—**Soot in Gardens.**—Why bury your soot in the garden? Dig it up and mix well with the soil; it will then be made immediately useful without any waiting before planting in any particular spot.—SAXON DEYNE.

1975.—**Soot-water for Plants.**—Tie soot up in a piece of coarse open calico or old muslin, then attach it to a stone or brickbat, and put in a tub or other suitable vessel. Fill up with water, and allow to stand for a day or two; then stir well several times. Let it settle, and use the clear liquid; but be careful that it is not too strong.—SAXON DEYNE.

1985.—**Glass for a Conservatory.**—If expense is not an object, plate glass may be used, and I think the plants will grow equally as well with ordinary sheet glass, but certainly no better; and if no better, why use more costly material?—SAXON DEYNE.

1971.—**Pruning Jasmines and Berberis.**—The Jasmines may be cut back now to the point where the buds are breaking, or lower if necessary. A somewhat similar treatment will suit the Barberries too—keeping in view the shape the shrubs are required to assume to maintain a symmetrical outline.—E. H.

1964.—**Making a Lawn.**—If the surface has been well cultivated and made fine and friable, rake off all stones that can be gathered up with a fine rake. If the surface be loose, firm it by treading or drawing a roller over it; then level it again with the rake. Sow the Grass seeds thickly, so that the surface appears dotted all over with them. Rake again and roll. The work should be done in fine weather.—E. H.

1985.—**Glass for Conservatory.**—Plate glass, if clear, is as good for plant growing as any other. Probably what is called Hartley's rough plate is meant in this case; and, though I should not object to the roof being glazed with it, I should prefer the upright sashes glazed with clear glass, as it admits more light, and in such a position shade would be unnecessary.—E. H.

1974.—**Soot-water for Plants.**—Tie the soot up in a coarse bag, and sink it in water. A piece of old canvas will do.—E. H.

1963.—**House Slops as Liquid Manure.**—The house slops may be diluted with water if too strong, and toned down so as to suit any crop. They may also be poured over any vacant plot of land that requires manure as they are, or over the roots of any fruit tree that looks weakly or exhausted. I have seen old worn-out Apple trees much benefited by such applications.—E. H.

1973.—**Soot in Gardens.**—Supposing the quantity of soot named was placed in one spot in autumn, scattered a little, and dug in with a fork or spade, the ground may be cropped now. If the soot was buried in one heap the better plan would be to lift it out and scatter it now before cropping the land.—E. H.

2048.—**Woodlice in Frames.**—Place a toad or two in the frames. Lay a few empty pots about on their sides, into which a wisp of hay has been thrust loosely; the woodlice will hide in the pots; or the pots may contain a slice or two of boiled Potato as a bait to attract them. Once or twice a day the pots should be examined and the insects killed.—E. H.

1934.—**Unhealthy Pear Leaves.**—If the trees are old and exhausted, or if the roots have penetrated a bad ungenial subsoil, the stagnation of the trees' system has prepared them for the reception of some fungoid attack which has caused the leaves to become discoloured, and if not arrested will ultimately kill the trees. Work in some fresh turfy loam round the roots, and mulch to keep near the surface. If the root-pruning does not produce the desired effect, cut back the branches and let up new heads.—E. H.

1935. — **Lobelias for Bedding.** — Lobelia erinus compacta is quite as suitable for an edging as L. Emperor William. Silene pendula and compacta are both rather tall for edgings; the latter is the best. White, blue, or yellow would look well with the Silene, and scarlet or yellow with the Lobelias.

1283.—**American Blackberries.**—An article on the culture of the Parsley-leaved American Blackberry or Bramble, appeared in GARDENING for May 17th 1879. There are several varieties besides those, lately introduced into this country. The advantage claimed for them is that they come into use after all our old kitchen fruits are over for the season.—J. D.

1969.—**Painting Greenhouse Floors.**—Do not attempt painting tiles, especially now they are laid down, and, of course, damp, which would inevitably make a mess of the paint. If a stiff besom and water will not keep your greenhouse floor clean, then I fear there is no help but to "grin and bear it."—SAXON DEYNE.

1973.—**Parsley for Exhibition.**—I have had good pots of Parsley by sowing the seeds in gentle heat in spring, potting off singly when large enough into 2½-in. pots, and to keep lifting them on as more root-space is required, until they occupy 6-in. or 8-in. pots. If a large potful is required, when the plants have filled 4-in. pots pack half-a-dozen into a 12-in. pot. Use good rich soil, containing a little burnt earth or some wood ashes.—E. H.

1980.—**Newly-made Lawns.**—Give a top-dressing now of fine-sifted wood ashes. It will encourage the finer Grasses to take the place of the eradicated Buttercups. Persevere with the spud and the roller.—E. H.

2051.—**Flowering Shrubs for Front of House.** If for training on house, plant Pyrus japonica and Lonicera grata. If to plant on Grass in front (and the question does not say which) plant Berberis Darwini and Arbutus Unedo (evergreen), or Magnolia purpurea and Venetian Sumach (deciduous).—E. H.

2052 —**Rhododendrons.**—Plant at once. The hybrids of Ponticum are the are the hardiest and cheapest; the Catawbiense hybrids are also hardy, and good for grouping. Among the choice-named kinds the following half-dozen are good and distinct—Blandyanum, Charles Dickens, Cyaneum, maculatum, John Waterer, perspicuum.—E. H.

2097.—**Garden Forget-me-not.**—If the plant mentioned bears a brilliant blue flower, with a white centre and very pretty ovate petiolate leaves, it is Omphalodes verna, and can be purchased at most nurseries. —MARK.

1956.—**Vines on Long-rod System.**—I should advise "G. B. M.," as his Vine is certainly ruined, and no crop can be expected at all this year, to rub off and break away all and everything which has been grown since winter, and continue to do so as it breaks afresh; thus encourage the lowest break to furnish a young rod for next year, which will ripen good wood for a sure crop for 1881, which can be got by no other mode. The following year treat this new rod as you like—spur or long-rod system. In winter cut out the old wood, not before; give plenty of ventilation.—T. G. K.

2061.—**Water for Greenhouse Plants.**—Is it necessary at this season (and during summer) when watering plants in a greehouse to have the water about same temperature as greenhouse? In winter I know there should be warm water added.—A. THOMPSON. [Water from a pump or well is not good for plants at any time. If soft water from a pond or open tank cannot be had, the best way is to fill a tub in the morning and place it in the sun all day. The water will then be ready for the plants in the evening, at which time all watering is best done through the summer months.]

2065.—**Dog's-tooth Violet.**—What is the botanical name of this? and is it related to the Cyclamen? [The common Dog's-tooth Violet is Erythronium dens canis; it is a native of southern Europe. The American species is Erythronium americana. The Dog's-tooth Violet belongs to a genus of Liliaceæ, and the Cyclamen to the order Primulaceæ.]

2066.—**Cultivating the Oleander.**—The flowers of my Oleander drop off, and last year it did not flower at all. How should I treat it?—KITTY. [The plant should be shifted in March into a compost of two-thirds sandy loam and one-third leaf-mould, keeping it in rather a close temperature for a time, but moving it when fairly established to a maximum of sun and air. An unheated greenhouse or frame is the best place for it. During the summer months copious supplies of water must be given; and if in hot weather, when the pots is full of roots, it is placed in a saucer, the plant will be much benefited. Occasional waterings with weak liquid manure will also prove beneficial. Cuttings may be taken in August of the current season's growth, inserting them in sandy soil and placing them in a close frame until rooted.]

2067.—**Azaleas for Greenhouse.**—I have a "poor man's greenhouse," which I heat with a paraffin stove; and during the last two severe winters I have managed to keep my plants, and I have now in flower Cinerarias, Primulas, &c. I want to know if I can keep Azaleas in such a house. If so, how are they propagated?—SUFFOLK. [If you could winter Primulas you can winter Azaleas in the house you mention. Your best plan will be to purchase a few small plants. Propagating Azaleas entails a good deal of time and skill.]

2063.—**Clematises and Jasmines.**—I have two of these 6 in. or 8 in. high, which were raised in heat. Should I harden them off before planting them out; and what sort of soil is best for them? and are they perfectly hardy to grow without protection?—NORFOLK. [Harden them off and afterwards plant them in sandy soil, to which some leaf-mould or rotten manure has been added. They are perfectly hardy, but it is a good plan to put a coat of ashes a few inches deep round the roots in winter.]

2069.—**Planting Hardy Flowers.**—How far apart must the following be planted in beds:—Petunias, Heliotropes, Ageratums, Alternantheras, Iresines? [The first three from 15 in. to 18 in. if they are to be pegged down; if not, they may be a little closer. Iresines 9 in.; Alternantheras 4 in.]

2070.—**Planting out Annuals, &c.**—How soon is it safe to put seedling Arctotis and Godetia and Mentone Daisies from cold frame into beds?—A. H. C. [It is safe now, if you harden them off first by giving all the air possible.]

2071.—**Yellow Daisies.**—What is the name and what the culture of the large yellow Daisies now to be seen in bunches in Covent Garden? Are they hardy?—A. H. C. [A variety of the Paris Daisy. Its name is Chrysanthemum frutescens Etoile d'Or. It is not hardy.]

2072.—**Cucumbers for Greenhouse.**—At what time should Cucumber seeds be sown to produce plants to grow in a greenhouse without heat? My place for them is about 6 ft. long and 2 ft. broad. How many plants will it grow for convenience. I am going to train them up the roof.—PRINTER. [Sow the seeds at once singly in small pots of light soil. Place a hand-light or bell-glass over them, or put them in a box with a sheet of glass over the top. Plant out when large enough, which will be in three or four weeks' time. Three good plants will be plenty for your space.]

2073.—**Getting Rid of Weeds.**—How can I get rid of a noxious weed commonly called Horsepipe; it comes up from a depth of 2 ft. on some Potato ground in my garden?—PELSALE. [Chop off the tops as often as they appear; the roots will then die.]

Raising Calceolarias.—*J. W. C.*—The seed of herbaceous Calceolarias may be sown any time between April and September, according to whether large or small plants are required, or when they are wanted to bloom.

Gloxinias in Cucumber House.—*E. N.*—A Cucumber house is too damp for Gloxinias to flower in. They would grow well in such a place, but when commencing to flower they want a light airy shelf near the glass.

Shading a Conservatory.—What is the cheapest method of shading the top of a conservatory?—MARY S. [Paint it with whiting and skim milk, mixed to the consistency of paint; or get a tin of "summer cloud" from a seed shop.

Gas in Greenhouse.—*W.*—Gas is at all times very injurious to plant life.

QUERIES.

Before sending queries it is well to consult the first volume of GARDENING, *which contains an immense number of practical articles and questions answered by men well acquainted with the subject.*

2074.—**Aponogeton distachyon not Flowering.**—I have a plant of this which has been growing at the bottom of an aquarium in a 4-in. pot for the last two years. It sends up very robust leaves, but no flowers have ever yet appeared. Water is occasionally running in from a fountain, and the sun is upon it about three hours of a day. Could any reader give me the reason why it does not flower? Would it be better for re-potting into a smaller pot in stiff loam?—AMATEUR.

2075.—**Mustard and Cress on Flannel.**—Will any one tell me the best and prettiest way to grow Mustard and Cress on flannel?—A. B. C.

2076.—**Annuals and Perennials for Rose beds.**—Will any reader say what annuals or perennials would look best sown between standard Rose trees? I do not wish for any which require to be raised in a hotbed, but sown in the open ground.—H. E. T.

2077.—**Celery as a Remedy for Rheumatism.**—Last year's Celery crop is nearly finished. We have found it to be very useful in rheumatic cases, and shall be much obliged if any of your readers can tell us whether an infusion made with Celery seed, with which our cook flavours her soups at this time, would be useful; and if so, how much Celery seed should be put into a pint of boiling water, the infusion to be taken twice a day as a medicine?—G.

2078.—**Non-flowering English Plants in India.**—Your many articles on successful horticulture, the preparing of the different soils, temperature, transplanting, &c., I have not only read with interest, but successfully, in many instances, carried out. I write from Mercara, situated at the summit of one of the ranges of the India Western Ghauts, at the high elevation of 4000 ft.; the climate during ten months in the year closely approximates to that of the south of England in summer and autumn, with a temperature seldom higher than 70°, and never lower than 50°. Vegetables and flowers of certain kinds grow well, either from seeds procured from the Government gardens at Bangalore, Central India, or from seeds exported from England. The sweet-scented Violet, Carnations, Pinks, Asters, and many annuals grow and blossom profusely; but there are two home plants in particular which persistently refuse to be acclimatised, viz., the Wallflower and the Sweet William. For the past two years I have raised the seedlings up in leaf-mould and river sand, transplanted them to the open, where they have grown larger and larger in size, but without any buds or blossoms. The Wallflower plant has been living in the open for eighteen months, has withstood two wet monsoons of 250 in. and 197 in. rainfall respectively, and afterwards enjoyed more genial weather: through all it grew to a height of 2 ft. 10 in., abundance of foliage, but no blossom. I shall be happy to adopt any plan your readers could suggest whereby the obstinacy of the plants non-flowering could be overcome, for where Cucumbers, Celery, and Watercress, &c., thrive the Wallflower and Sweet William should blossom.—M. WOODHOUSE.

2079.—**A Suggestion for Hotbed Material.**—I have often noticed the great heat developed in the heaps of refuse or sweepings of machine makers' shops, consisting of oiled cotton waste, mixed with iron filings and turnings. Could not this material be utilised for hotbeds and propagating frames in the neighbourhood of manufacturing towns, where it could be had for the carting? A few experiments would settle whether the heat could be made steady and lasting, and whether the fumes exhaled would be injurious to plants.—J. D.

2080.—**Glazing Without Putty.**—Will "Arundo" kindly say where Hellewell's patent clips are to be got, and whether the glass squares should overlap each other at all, or be laid flat end to end? If the latter, there must, I suppose, be a slight space between them for the clip; and would not the wet get in there? I presume the purlines are simply squared, and have no rabbets at all. Would this system do for the upright part of the house —F. H.

2081.—**Cinerarias after Flowering.**—Would any reader tell me how to manage Cinerarias after flowering? and the best way to keep them for flowering next year? —C. J. B.

2082.—**Soil for Rhododendrons.**—I have a bed of (chiefly) alluvial soil in which I want to plant Rhododendrons. Are they likely to succeed in such soil? Will some one give me the names of about six kinds, most likely to do well in this locality, and with some variety of colours? —A. B. G., *Wisbech.*

2083.—**Stand for Exhibition Flowers.**—Will some one give me particulars of what they think the best and most convenient stand for exhibiting blooms of Pansies, Tulips, &c., and the simplest way to make one? I should have to procure the stand at once.—ARTHUR.

2084.—**Gnats Stinging.**—Can any one give me a receipt for the prevention of stings from these insects during summer?—PAX.

2085.—**Heating by Paraffin.**—By placing the paraffin lamp or stove outside the greenhouse how is sufficient heat got inside? I am compelled to use paraffin, as I am away from home twelve hours each day, therefore can give it no attention during that time.—W. B.

2086.—**Propagating Frames.**—Can any of your readers inform me if they have had any practical experience of Rippengille's frames for raising seeds and cuttings? or, if not, how could a cheap one be made?—M. P.

2087.—**Raising Seeds**—Can Loaca and Cobœa scandens be raised from seed without bottom heat? How soon will they blossom?—W. S.

2088.—**Treatment of Daphnes.**—How should I deal with evergreen Daphnes, which have flowered in pots in a greenhouse this spring, to bring them on into good flowering condition again next spring?—A CONSTANT READER.

2089.—**Dandelion for Salads.**—I have heard that Dandelion is a useful addition to the salad bowl. Is the common wild Dandelion, which grows in fields, &c., fit to eat, or must it be cultivated from seed as a vegetable? If so, I should be glad to have directions as to its culture? —AUREUS SCARABEUS.

2090.—**Ferns in Vineries.**—I have established a small Fernery in my greenhouse under a Vine. The Ferns do very well, but they are all of the common kinds, and lose their foliage in the winter. Will some one name a few evergreen Ferns that will stand a winter temperature of from 40° to 60°? My greenhouse is warmed by a brick flue, but the fire is only lighted on very cold nights, to keep the frost out. I have kept Lycopodiums green and growing all through last winter, also some Geraniums and Fuchsias.—SUBSCRIBER.

2091.—**Climbers for House Roof.**—Can any reader suggest a creeper, or other easily procured plant, to cover the roof of an outhouse. The plant must be grown on the roof, not from the ground; also a nice trailer for trellis 6 ft. high.—ANON.

2092.—**Cultivating Blackberries.**—Can any one tell me the best method of cultivating the Blackberry? I have had a root in my garden for many years which has yielded good fruit, but I think it might be much improved by proper cultivation. I train it against the pales, cut away all suckers, and trim it every winter.—HORTUS.

2093.—**Propagation of Clematis.**—How and when should I propagate Clematis Jackmanni, and its kindred?—A. H. C.

2094.—**Propagating Cistus.**—How should I propagate dwarf shrubby Cistus? I have a border edged with three colours of them, which has been a great success for many years, but age or the cold winter has made them very shabby this year, only the points being green.—A. H. C

2095.—**Slugs in Frames.**—Can any reader give a receipt for the destruction of slugs in a cold frame and greenhouse?—NEMO.

2096.—**Geraniums not Flowering.**—I have a glass structure (small) in which I have placed several Geraniums, &c., and I find that the flowers do not open fairly; in fact, they only partially open. Can any one suggest a cause and remedy?—E. C. L.

2097.—**Planting Flower Beds.**—Having just gone into a house to which is attached a garden laid out in flower-beds, and, being totally ignorant of gardening, I would be glad to know whether it is too late to sow seeds

in the open (I having no greenhouse) to blossom this year; if not, what had I better sow? The works on gardening which I have consulted do not give me the requisite information.—IGNORAMUS.

POULTRY.

FEATHER-PLUCKING.

MANY remedies and suggestions have been made at different times as to the best means to be adopted either for curing or preventing the troublesome and disgusting habit of feather-plucking, so common amongst fowls when kept in confinement. Various have been the theories propounded as to how the birds first acquired the habit; but these, like many other theories, were often very wide of the true cause. It may, therefore, be useful if we devote a little space to the consideration of this disease—for such it really becomes—especially as we find that some of our readers are troubled by their fowls plucking and disfiguring one another. When birds have their liberty, there feather-plucking and eating is totally unknown; and even when birds have learned to do this, on being restored to liberty they at once discontinue the practice. But when kept in small places, no matter what the variety may be, sooner or later this scourge—harmless so far as the health of the birds is concerned—is almost certain to make its appearance unless the owner is particularly careful and attentive in managing his fowls. We have only to consider what the natural habits of fowls are, and we then have the cause of their eating each others' feathers when confined, and are also able to devise means by which this may be stopped and prevented in the future. When fowls are kept under favourable conditions, with an unlimited run, we find that during the greater part of the day they are occupied mostly in searching for food; and when their appetites are satisfied, and they have become tired, then they retire to some quiet or secluded spot to arrange their feathers. At the conclusion of their toilet they will probably take a few minutes' doze, after which they awake, and renew their hunting expedition in search of insects and other kinds of food. Thus they are fully occupied, in a healthy and natural manner. But contrast these conditions with those under which specimens kept in confinement have to endure, with nothing to engage their attention or to amuse them, and only a few yards in which to exercise their legs, and still less space to stretch their wings.

Kept under these artificial conditions, it is not surprising if fowls, in common with man, soon fall into bad habits and acquire unnatural and morbid tastes, which in the case of the former generally develops either into feather-plucking and feather-eating, comb-pecking, or even to the partial eating away of parts of one another's bodies. To some it may hardly seem credible to hear of one bird partly devouring another, but such cases are by no means rare where fowls are confined in small places with nothing to occupy their attention. We have met with cases in which the birds have been so cleanly plucked as to leave no feathers on the body except those in the tail, wings, and a few on the head and the back of the neck. In others we have seen parts of the skin eaten away, so rapacious do hens become—for these are the culprits—not from any want of proper food, but solely because they were huddled together in small plaees with nothing to amuse them. During the winter, when the hens are not laying, these morbid cravings for injuring one another are partially if not quite discontinued; but as the time approaches for them to recommence laying, then the desire is again renewed.

From the preceding remarks it will be seen that we attribute feather-plucking and similar other unnatural habits solely to confining birds in small and limited runs. We are aware that other writers on poultry have affirmed that feeding with too much animal food has produced the same unsatisfactory result. We, however, know from practical experience that however much animal food may be given, fowls having their liberty never pluck one another. And here we have at once the obvious cure for the evil—occupation and employment for the birds, even when kept in confinement; the bottom of the run laid with loose fine gravel sand or cinder ashes, and the top covered with straw or coarsely cut chaff. Amongst this loose litter well scatter the corn, so that the birds will be obliged to scratch and diligently hunt after every grain. A stump of a Cabbage or Lettuce, or a few leaves tied together and suspended by a string a few feet from the ground, to compel the birds to jump up to get at the green stuff, or a bone with a little meal on it, hung in the same manner, answers very well. Many other dodges will occur to any one who gives the matter a little attention; and by adopting these simple plans much annoyance and disappointment in the keeping of poultry may be prevented.

Weight of Eggs.—I keep fowls for the pleasure of new-laid eggs, and, as your correspondent "H. D." says, there are "eggs and eggs." After trying many sorts, I have for the past three years adopted the Minorcas—non-sitters and splendid egg producers. I put twelve eggs in the scale to-day which averaged 3¼ oz., two of them weighing 4¾ and 5 oz. During last season I had many eggs weighing 4 to 5 oz. from hens two years old.—F. P.

Feeding Sitting Hens.—It is best to take the hen off the nest each morning, and let her have a good supply of Barley and plenty of green food, such as Grass cut from a lawn, Cabbage, or Lettuce leaves. There should always be clean fresh water in abundance, and if the hen is liberally supplied with green food she will not be likely to drink so much water as to be injurious to her. By taking her off the nest each morning and allowing her to dust her feathers amongst some old mortar or cinder ashes, she has an opportunity of relieving herself, and of freeing her body from insects. She then sits more quietly and closer, and makes finer eggs than when these little matters are not attended to.

Chickens Dying.—"Rhoda" should cut away with a pair of sharp scissors the small feathers and the accumulated excrements which have collected around the vent; then bathe the vent with a sponge and warm water, removing all dirt. We fancy there must be something wrong with your feeding: at least it can do no harm to change the diet; and above all see that the ground or the place where the chickens are fed is free from all droppings.

Fowls Losing their Feathers.—Your hen is broody, and when this is the case the feathers on the under part of the body often drop out.

Fowls' Claws coming Off.—The toes of J. Sice's bird have been frost-bitten, and they will not grow again.

Leghorn Fowls.—The Leghorn is a hardy, precocious bird, bearing confinement very well. They, however, in common with the non-sitting varieties when confined too closely, are much addicted to the disgusting habit of plucking out and eating each others' feathers.

Pale-yolked Eggs.—The colour in the yolks of eggs often varies, the same as the colour of the shell; but this is of little consequence so long as the birds lay well and the eggs are good in flavour. The yolks of eggs laid by black coloured birds are often lighter in colour than those obtained from Cochins and Brahmas. Eggs from the latter are generally very dark in colour, and consequently very rich in flavour; in fact, we know of no other variety which approaches these for the richness of their eggs.

Fowls Eating their Eggs.—The best way is to kill them at once and risk purchasing others with more high-bred habits; you cannot cure so vicious a practice in fowls.—E. F.

—— When once fowls have acquired the habit of eating their eggs there is no cure, and unless they are valuable ones they should be killed.

Disease in Fowls.—Chop rue fine, mix it with butter into pills, and give each fowl a pill every day until improvement takes place. External remedies are futile.—A FOWLER.

Eggs for Hatching.—In answer to "E. S. W." as to whether eggs from birds ten months old are fit for hatching, I say Certainly It is, however, generally found that chickens hatched from eggs laid by two or three year old hens turn out bigger and stronger birds.

Eggs not Hatching.—Would "Andalusian" inform me where the egg-tester he spoke of in last week's GARDENING is to be procured? also the reason why eggs are not hatched? My hens only hatch three or four out of a sitting. I find upon breaking them to contain chickens which appear to have been dead a week. I keep thirty-three hens and three roosters, Spanish, Dorking, and Brahma.—POULTRY MAID.

Fowls with Diseased Legs.—I have five pullets and one cock (Brahmas). The pullets are in a healthy condition and lay well; but the cock has something the matter with his legs: they started by turning red and swelling, now they are festering round the stumps of the feathers. The fowls have a large airy house, a run of nine square yards, are fed regularly twice a day, and kept clean. Can any one kindly tell me the cause and cure?—S. D. A.

Brahma Hens Sitting.—What length of time does a Brahma hen keep laying after the brood has been taken from her before she wants to sit again? On the 2nd of February last I put some duck-eggs under her, which she hatched on the 29th; on the 22nd of March I took her away from them and put her along with the other fowls again, and she commenced laying on the 29th. Since then she has laid, say, two eggs every three days, and on Sunday last she laid an enormous one, which weighed 3½ oz.; and I am told they generally lay a large one just before going broody. If this is so I shall be glad to know, as I shall keep a number of her eggs for sitting.—W. G. D.

AQUARIA.

I HAVE read with interest the various articles that have from time to time appeared in GARDENING on the above subject, and, like "W. B.," have myself had some experience in their stocking and management, and therefore venture to offer a few remarks. Your correspondent, H. G. Sunderland, the other week, tells us we must not have a fountain in our aquaria, or the "fresh water will kill the fish." Now an aquarium with a fountain will, by reason of the continual flow of water, not only sustain more life in proportion to its size, but will bear a greater temperature in the room where it stands without distressing the inmates. Next he tells us that Valisneria and Anacharis are the best of plants, but the former looks the best and grows the fastest. Now, while I agree that Valisneria is the best of all plants for an aquarium, I must say that it is not to be compared to Anacharis for rapid growth; indeed, the way in which the latter will spread and choke up a tank is the only drawback to its use; but that can soon be remedied by simply drawing part of it out of the water.

"W. B." (April 17) is more liberal in his selection of fish than "H. G. S.," but he proscribes all beetles; and he says, Do not be persuaded to add "any other insects" to your collection. Specimens of Colymbete, Gyrinus natator, and Hydrous piceous, may be safely trusted in a general tank; indeed, the lively antics of the two former will be a great attraction; and then the curious straw-worm or caddis (larva of Phryganea grandis, caddis fly) is a most amusing tenant in the spring.

Let me warn beginners in aquaria-keeping against being in a hurry to see their vessels full of fish. Let your plants get established before introducing any animal life, and then do not overcrowd them; it is not only dangerous but cruel to cramp the inmates up as I have seen them done. I notice that most of your correspondents use glass for their vessels. Now, I prefer to imitate nature as closely as possible, and for this reason in my general tanks I do not use any vessel that will admit of lateral rays of light; your inmates are seen to the best advantage in a vessel lighted only from the top. Now, my own tank, of 16 or 18 gals. capacity, is made of wood, and sunk in the ground in my Fernery; round the edges is a sloping bank of virgin cork, which overhangs to the water; on this I grow Liverworts, Mosses, and some small Ferns. In my tank I do not trouble about many plants, preferring to depend for the supply of oxygen to the confervoid growth with which the sides are abundantly covered. Thus I come nearer to a natural condition for my finny pets than exposing them to a glare of light near a window; for, be as careful about shading as you will, there will always be times when old Sol suddenly pops out, and you are not in the way to screen them.

The higher development of the aquarium I have not seen touched upon in your pages: I mean the cabinet aquarium, as it is sometimes called. If it would be of interest to your readers, I shall be glad to forward description, &c.; or perhaps some other reader, who is more experienced in the subject, will do so. Then there is the aquarium as a water garden, in which at proper time and season most of our best aquatics can be shown. T. CHADBURN.

Cure for Wireworms.—Some readers of GARDENING may be glad to know that a few plants of Double Daisy in a bed are a complete protection from wireworm to the remainder of the plants.—H.

Garden Ornaments.—Old rustic stumps and trunks of trees when tastefully arranged are very ornamental in the flower garden; but when these cannot be obtained a good substitute may be had at a small cost, viz., American cheese boxes. To make them I take three round pieces of wood of equal lengths and nail them together so as to form a stand; then nail the cheese box on the stand, and cover the outside entirely by nailing on the bark taken from old trees; burn three or four holes in the bottom for drainage, and fill with mould. When planted with bright flowers they look very nice; the Tropæolums are well suited for this purpose. The boxes may be purchased at most grocers, and the bark at the timber yards.—F. R.

GARDENING

CLIMBERS ON TREES.

MANY a garden might be made much more interesting and beautiful than it now is if the system of garlanding some of the stronger-growing trees contained therein with beautiful climbers were adopted. In the case of some trees it would not be advisable to cover them with strong-growing climbers as they might sustain injury thereby; but there are always trees in gardens upon which a Honeysuckle, a Clematis, or a Rose might be allowed to ramble without fear of injury. Then, again, trees or shrubs which have assumed a sickly aspect might be ornamented in this way with advantage. The accompanying illustration, drawn and engraved from a photograph in May, shows an old and vigorous plant of the handsome and hardy Clematis montana allowed to have its own way to some extent. This climbing shrub, of which the large-flowered variety called grandiflora is grown here and there on walls, is most precious for those who wish to garland trees and stumps and hedges with lovely flowers. It is as hardy and free as the common English Clematis Vitalba. The Clematises are so numerous, so hardy, so beautiful in flower and so singularly varied in the colour and form of their blossoms, that whole wild gardens of beauty may be formed of them alone. The woodcut on page 113, which was prepared for "The Wild Garden," represents a Clematis montana on the branch of a Yew tree, in which the flowers of the Clematis can be seen more prominently than in the engraving on our front page. Climbers do better if planted before the trees become too old or the soil exhausted. In the case of any old tree it may be desired to clothe, some of the exhausted soil should be removed, and some fresh rich material substituted. But the new soil must not be placed much higher up the bole than it was covered by the old soil, or some mischief may arise to the bark of the tree and its health be injured. The Wistaria, if planted before its support has become old, will combine with excellent effect with any single specimen of not too dense a habit. Of course, the Beech should be avoided. Some time ago we saw a Weeping Willow, on the margin of a lake, that had its trunk clothed with Virginian Creeper, and the effect in autumn, when the sun shone through the drooping branches of the Willow—whose leaves were just becoming tinged with gold—upon the crimson of the creeper-covered trunk was rich in the extreme. The Everlasting Pea, both the rose-coloured and the white varieties, are very suitable for planting near small-growing trees, such as Laburnums, Thorns, or standard fruit trees, when such are grown in or within view of the grounds. In small places, where the orchard trees are planted on or near the lawn, some interest may be added to the plantation by covering the stems with some strong-growing creeper that is not easily destroyed; and we have seen these Peas used for the purpose with good effect. Of course, they cannot be planted in orchards to which stock have access, as in such cases nothing would be permitted to live. Even the trees, until the stems become old and gnarled, must have protection. The Hop is a very effective plant for draping a thin specimen Arbor-vitæ or Yew tree, but the shoots should be thinned out in spring, and not more than three or four allowed to climb up to the tree. When the leader emerges from the top of the bush and throws its long graceful wreaths of Hops over the dark green foliage the contrast is most effective. In like manner, the taller stronger varieties of Tropæolum could be used on shrubs towards autumn without doing any harm, as the first frost would kill them, and they could be removed. After the first year there would be no occasion to plant any seeds of these Tropæolums round the shrubs, as enough would fall and winter in the ground to furnish sufficient and to spare. Clematises are well suited to plant at the base of deciduous trees and even Yews, especially those with light-coloured flowers, which are set off to advantage by the dark background. The Honeysuckles, Jasmines, and climbing Roses, too, are favourite plants for garlanding trees. We have seen a large variegated Holly, from among the thick branches of which hung showers of blooms of the red and white York and Lancaster Roses with excellent effect, and this, to all appearance, without doing the slightest injury to the Holly, and we have also seen the Wistaria hang

CLEMATIS MONTANA GRANDIFLORA GARLANDING TREES.

down in long festoons from the head of a common Fir tree probably 50 ft. in height.

In the rougher parts of the grounds, such as in shrubbery or woodland walks, there are many hardy climbers which could be used with equal advantage, such as Apios tuberosa, a North American plant of the Pea family, that bears reddish flowers with a perfume similar to that of Violet blossoms. The common Tamus (T. communis) is a pretty plant for a similar position, as is also the Tamus-like Hablitzia (H. tamnoides), a plant of rapid growth, and one which is covered for some weeks in summer with a profusion of small blossoms produced in dense racemes. The Cucumber family also yield some graceful climbing plants; for, besides our native Bryony (Bryonia dioica), there are Echinocystis lobata and Thladiantha dubia, both hardy and vigorous-growing plants. Several of the species of Smilax are quite hardy enough to admit of being grown in sheltered positions, and very pretty climbers they make when well established. The kinds best adapted for such purposes are S. aspera, hastata, mauritanica, and excelsa. The Dutchman's Pipe (Aristolochia Sipho), as well as A. tomentosa and A. altissima, should always be included, as they will grow anywhere, but nowhere better than in sheltered shaded places. The Canadian Moonseed (Menispermum canadense) is another pretty plant, and one which has a charming appearance in early summer when covered with its long racemes of white feathery blossoms. M. dauricum is a kind not sufficiently known at present to speak correctly of its merits, but probably it is as desirable as its congener. Schizandra coccinea, a plant belonging to an allied family, and similar to the foregoing Moonseeds in appearance, is also well worth notice, as its small fruits, which are bright red, have a pretty effect.

Trees and Shrubs for Wet Ground.—I know of nothing more profitable to grow, or that will succeed better in wet land, than the Alder. When once the plants become established, it is astonishing how quickly after being cut down they start again and yield fine poles, that is, if protected from the attacks of game, such as hares and rabbits, which are fond of nibbling the young shoots as they start into growth. Next to Alders in point of profit and suitability for wet land stands the Ash, the wood of which always meets with a quick and ready sale. Elm, too, does well where it can get plenty of moisture at the roots, and it is only when so favoured that it keeps healthy for any length of time, or acquires much size; when sound and large, Elm trees are valuable. By planting the two last named at wide intervals, the Alder will be found to do well between them, and come in as a sort of undergrowth, an arrangement by which there would not be many years to wait before the ground would yield some return. If any shrubs or plants are wanted by way of ornament, the common Rhododendron, Bambusa Metake, Arundo Donax, and a few plants of Pampas Grass might be used, and, if judiciously arranged, would form quite an interesting plantation. Evergreen Oaks interspersed here and there, and some of the Coniferæ, such as the Austrian Pine, Pinus Laricio, and Abies Douglasi, would also have a good effect, but if the land be very wet, it may be necessary to plant these on raised mounds. —S.

Magnolia conspicua.—This beautiful flowering tree, which looks so well in the form of a single specimen on Grass, with its branches bending under a load of pure white blossoms, will soon be in full beauty. I have on many occasions used its flowers for Easter decorations, a time when white flowers are in such great demand. This year, however, the buds scarcely showed signs of swelling at Easter; therefore this Magnolia is quite a month later than usual. —J. G. M.

UNDERGROWTH FOR SMALL SHRUBBERIES.

NEAR towns it often happens that small villa lawns are bounded by a little plantation of tall deciduous trees or shrubs, the ground under which is usually left bare. This need not be, as there is a variety of plants which would form a beautiful undergrowth. There are several common low-growing hardy herbaceous plants which will live under the shade of deciduous trees, and which, with little expense or trouble, might be planted in large patches, and produce quite charming effects, especially in spring.

If the ground in the plantation has become hard, and the autumn leaves have been annually swept away, it will be necessary to dig it, at least in patches, and put in some leaf-mould or or other dressing, and freshen the soil before planting any herbaceous plants. But when the injurious process of annual digging has been carried on, the ground will probably be in fair condition to receive hardy free-growing plants at once; and when they are established there need be no more rough digging and exposure of the earth, which Nature always is willing to hide.

The common Lungwort (Pulmonaria officinalis) is an excellent covering for bare ground partially shaded. A small patch of it in the herbaceous border gives but a poor idea of its real beauty when allowed to cover a plot as big as a small dining table, with its shapely leaves and mixed pink and blue flowers. It is free-flowering and continues in beauty for a considerable time; the leaves, indeed, remain till the frost cuts them off in winter, and they show themselves again early in spring. This Lungwort has also the merit of being a very good flower for indoor decoration, lasting a long time in water, and coming early in the year; it ought to be planted where it can occasionally catch a glimpse of the sun before the trees are in leaf. The variegated Dead Nettle (Lamium purpureum maculatum) is another plant which, after once being put in, will give no further trouble, and will grow under tall deciduous trees, covering the ground close with well-marked leaves for nearly all the year, not to mention its pink flowers in spring. The well-known Periwinkles (Vinca major and minor), blue, white, and coppery, deserve permission to ramble over any shady space not regularly cultivated. Here and there clumps of hardy spring bulbs might be allowed to push their way through these Vincas. Closely surrounded by Ivy or any low-growing carpeting plant, a group of Martagon Lilies (Lilium Martagon) would have a good effect. The colour of these Lilies is not bright; botanists call it "winey-red," but whatever it is called it is not much to boast of. It is the shape, the outline of the Lily which is so strikng: whorls of leaves up the stem, and at the top ten to thirty blossoms, with petals well turned back on the foot-stalk, and of so firm a substance that they might be wood carvings, and ornamented by stamens so long and delicate as quite to set the wood-carver's art at defiance. The anthers are bright orange, and a good contrast to the "winey-red." These Lilies will grow in any shade, and look well either in groups or otherwise. They might have a little manure when planted, but afterwards they will take care of themselves. Martagon Lilies used to be common enough; but so many good things are now little known, that I feel the necessity of introducing them as if they were novelties. There is a scarlet Martagon (Lilium carniolicum), the colour of which is all that could be desired; but I do not think its general aspect is so stately and fine as that of the common Martagon. It does not grow so tall, and the plant is less striking from the leaves being scattered instead of being arranged in whorls. It will grow where direct sunshine never falls, but I am not sure that it will flourish so well as the common Martagon quite under the thick shade of trees. Lily roots of any kind must not be kept long out of the ground.

White Foxgloves would make a bold group among low herbs, but to ensure their growing tall, strong, and fine, the soil into which either the seeds or young plants are put must not merely be dug, but well enriched with manure; and though Foxgloves in favourable positions, where they grow naturally, sow their own seed, and never fail year after year to yield spikes of bloom which tower over nearly every other British wild flower in conspicuous beauty, I cannot promise with such certainty that where they have been artificially introduced we may come again and find them at the end of twenty years, as in the case of the Martagon Lilies. Then there are Columbines (Aquilegias), plants of excellent habit, bearing flowers of great beauty. Very interesting in the early spring is the quickly-growing tuft of well-cut blue-green leaves, from which in time rise firm stems, never untidy, always carrying scores of pretty nodding blossoms of various colours. Once established they never need be noticed again, except to enjoy them. Let a packet of good seed be sown in ground ever so lightly prepared, and the hardy English Columbine will take care of itself.

I should like to see some of these bolder growths in close association with a large stone or two; or one really big stone would perhaps look even better. It may be of any shape, but must be in a natural position. Close against such a stone, over which a spray of Ivy might run, a group of Lilies would look particularly well. Three or four smaller but sizeable stones among a cluster of Foxgloves would help to give them shelter, and preserve the moisture about their roots, and look natural and picturesque. Where a great many cut flowers for indoor decoration are required, I can recommend two hardy things which will grow under trees, and which only ask to be well started and then let alone; far from requiring to be taken care of, each of these takes such good care of itself that the trouble would be to get rid of it. But if too rambling to be admitted into the borders, where order is of importance, their obstinate permanence makes them all the more valuable in a part of the grounds where we want something pretty but not troublesome. One of these desirable plants is the creeping Campanula (C. rapunculoides); its flower-stems stand 1 ft. or 2 ft. high, with gracefully-drooping bell-shaped flowers of a purplish-blue colour. Except for its habit of spreading underground and coming up in unexpected places, it is by no means an untidy plant, being almost entirely out of sight when out of blossom. The same may be said of the Leopard's Bane (Doronicum Pardalianches); its blossoms are like golden stars on long flower-stalks, particularly convenient for vases. It used to be common in cottage gardens, and, though probably introduced, has made itself wild in some places; but, like many other old and good things, the difficulty is now to get a plant of it. H.

Layering Roses.—There are no means by which stout-blooming plants on their own roots can so quickly be had as by layering. Where dwarf Roses are grown, either on their own roots, grafted, or budded low, and the shoots pegged down for flowering, a large number may be had by the end of the season on their own roots without much interfering with the blooming during the present year by layering. Supposing the shoots so pegged down have been left about 2 ft. long, and a tongue is made by cutting with a sharp knife one-third through the shoot in a slanting direction towards its point, and about 9 in. from the end, and the shoot at this point is pegged down in the soil—removing the latter so as to get the shoot at this juncture about 2 in. below the surface, using a stout, hooked stick, that will hold it in position, covering it up, so as to leave two or three eyes at the point bare—these will make strong shoots, forming the head of the future plant, which, during the summer, will push plenty of roots at the point where tongued. Nothing further will be required except severing from the parent plant in the autumn. The lower portion of the shoots so pegged down, as well as the portion at the point left above ground, will produce strong flowering growth through the summer; and in this way the quantity of plants may be increased to an extent only limited by the number of strong shoots available, with very little loss as to the amount of flower during the present season.—A. B.

VEGETABLES.

Sticking Peas.—Various modes of sticking are practised in different parts of the country, but none of them beats Pea-sticks made of tops of trees or underwood; Hornbeam is perhaps as good as any when it can be obtained; Hazel and Ash, too, are often used, and answer the purpose admirably. In preparing the sticks they should be made flat or fan-shaped, just taking off the straggling shoots at the top, in order to give them a neater appearance; little time need be spent in sharpening—one usual cut made in a slanting direction being all that is needed; a little judgment must, of course, be used in cutting them to the required length for each variety, too short sticks being comparatively worthless; care, too, should be taken to place them wide enough apart at the bottom, and upright,—*i. e.*, not sloping inwards at the top, as is usually the case, allowing the haulm to escape at the sides, instead of finding its way to the top inside the sticks. In the case of very tall Peas it is a good plan to put a short stick and a long one alternately on each side of the row; when, however, sticks cannot be had readily, a few stout poles or stakes driven firmly into the ground, 5 ft. or 6 ft. apart on each side of the rows, will answer. These should be all of one height, which should be that of the Peas; some tar twine or other strong cord should then be tied to the end stake and passed along the line, making a turn on each stake within a few inches of the ground, and as growth progresses the next turn should be raised a little higher up, and so on until the plants have attained their full height. If the string or cord be applied at the right time, the tendrils of the Peas will clasp firmly round both stakes and strings, and will support the plants almost equal to Pea-sticks; some, indeed, think this plan best, as by it the plants are exposed to more light and air than they otherwise would be, and the pods are more easily picked without injuring the haulm. Light galvanised wire hurdles are likewise used in some places for supporting Peas; and they are not without merit, inasmuch as they are neat, are speedily applied, and last long. Market gardeners seldom stick their Peas; they allow them to come to maturity, then pick them and pull them up. They are seldom gone over more than once or twice; and for market purposes this answers very well, but where a continuous supply is desired sticks are decidedly needed. When they are not employed, stopping the points of the shoots is often practised to induce the plants to grow more dwarf and bushy, which in this case is no doubt advantageous; but, as a rule, little is gained by stopping. It is said by some to throw the energy of the plants into the pods, but it is a question if it be not as harmful as beneficial. Where a crop of Peas is required to be fit for use on a given date, and where from all appearance it is not likely to be ready by that particular time, we have frequently seen the tops of the shoots removed, and only the most forward of the pods left. The moulding-up of Peas after they have been sticked is generally done with a spade; a line is stretched along the side of the row, in order to make straight work, and the soil is then carefully placed round the bases of the plants. Too much soil should not, however, be put around the stems of Peas, as the roots push from the stems with considerable reluctance, and the earthing-up throws off the water instead of allowing it to descend to the roots.

The Onion Maggot.—This is the larva of a fly that deposits its eggs amongst the leaves of the plant, and works its way down to the bottom of the bulb; and when they attack the crop they most generally destroy or seriously injure it. The Onion is much more subject to the maggot in light soils than in heavy land, especially in old worn-out gardens. I have tried various remedies that have been recommended for its destruction, or as a preventive to its spreading; but I have never found anything that was of use after it once attacked the crop. By a judicious preparation of the soil, and the use of some manures, I have found that its attacks were rendered less frequent. In light land, the addition of liberal quantities of new soil, with a good dressing of salt (½ lb. to the square yard), applied as a surface-dressing during the autumn or winter, with 1 in. of soot pointed into the ground before sowing, renders the crop less liable to its ravages. It would appear that the smell of soot is distasteful to the fly, and prevents it depositing its eggs; but, whenever they have come to life, the soot-dressing overhead, often recommended, I have found of no avail.—H.

Salt for Onion Beds.—Where attacks of maggot are feared on Onion beds, ½ lb. of salt scattered broadcast will do much towards remedying the evil. If the seed be already sown the salt may be applied, but if sowing have not taken place, the ground before being drilled should be sprinkled over with salt, and have a good raking in order to distribute it well. If a slight dressing of salt be applied to Onions after they have made their appearance above ground, it will greatly increase the growth of the plants, as well as help to preserve them from the attacks of maggots.—J.

The Highfield Grape Tomato.—This singular hybrid, the produce of a cross between the Currant Tomato and Hathaway's Excelsior, is apparently a most valuable kind, as it withstands the disease long after others have been killed off by it. The bunches of fruit range from 9 in. to 18 in. in length, the fruit being as large as the berries of the Gros Colman Grape and finely flavoured. It is a capital kind to stew whole.

Vegetable Marrows.—I grow two varieties of Vegetable Marrow, viz., the Large White and the Improved Custard, the seeds of both of which I sow in April or early in May. I fill a 6-in. pot with loam and leaf-mould, on which about half-a-dozen seeds are put round the edge, and the pot is afterwards placed in a heat of 60°. In this temperature the young plants soon appear, and as soon as they form the first rough leaf they are potted singly into 4-in. pots, and gradually hardened off until the last week in May, when they are planted out. I have planted them on an ordinary kitchen garden border, but I never had them so fine as I had them once on a heap of garden refuse in a reserve ground. I have also found them to be more fruitful when pretty closely pinched in than when allowed to ramble about as they generally do.—A. N.

Tripoli Onions Sown in Autumn.—Where large mild Onions are required for cooking, these can only be got by giving them sufficroom. They should at once be thinned out 8 in. or 9 in. apart; and, if the soil was not sufficiently rich at the time of sowing, the produce will be much larger if it now receives a sprinkling of guano and soot, mixed in equal proportions. Delicate-flavoured Onions are very much esteemed for culinary purposes; but, unless they are grown freely in soil well enriched, they cannot be had.

Broccoli in Succession.—The following kinds, if true to name, I find will give good succession of compact white heads from November until June:—Snow's Winter White, Veitch's Early White, Dilcock's Bride and Cattell's Eclipse. Some of the latter should be planted on a north border, to make them as late as possible; and should be succeeded by Walcheren Cauliflower, which, sown at the end of August or beginning of September, and wintered under hand-lights or frames, would come into use at the end of May and throughout June. These should again be succeeded by Walcheren and Veitch's Autumn Giant, sown on a slight hotbed in February; the Walcheren would be in throughout July, followed by Veitch's Giant through August and September, and both would be succeeded by the same sorts sown early in April, which would last until Snow's Winter White came in, thus keeping up a good supply the whole year, unless destroyed by severe frost. I had a splendid lot of Autumn Giant throughout last August, and kept some in an early Carrot frame.—G.

Watering.—Although the soil is now in moist condition; yet, should we have an absence of rain for even a short time, the ground quickly becomes dry, and surface-rooting plants soon suffer unless water is given them. It is necessary to impress upon amateurs that it never should be given until absolutely required, and, when applied, it should always be in quantities sufficient to moisten the soil as far down as the roots penetrate; when this is not done, it merely excites the surface-roots, leaving those that are deeper, and generally of more importance to the full development of the plants, in a comparatively inactive state; and, unless these surface-roots, excited by this sprinkling system of watering, are kept supplied, they perish as quickly as they are formed, in which case the plants so treated suffer more than if no water had been given. This applies with equal force to both flowering plants and vegetables. To all to which water is given, give it thoroughly, even if some things be left without altogether; this will be found better than sprinkling or half-supplying the whole.

Chrysanthemums.—To grow these really well in borders, they should never stand longer than a year without being renewed or renovated, and instead of a large number of stems being allowed to grow up together, they should be limited to three or four at least. Being naturally of a gross-feeding nature, it is necessary that the ground where they are to be planted be deeply trenched.—G.

The Flame Nasturtium among Rhododendrons.—Twelve or fourteen years ago, I planted this among and near the margin of large masses of Rhododendrons, and each year it grows up among them most luxuriantly about 8 ft. high, flowers beautifully, and is much admired. The natural soil is a rich light loam. The choice kinds of Rhododendron are planted in peat. This plant does as well on the sunny as on the more shaded side of borders.—J. G.

The Thread-leaved Adam's Needle (Yucca filamentosa).—This is one of the best of

Thread-leaved Adam's Needle (Yucca filamentosa).

the Adam's Needles for small gardens. It seldom fails to flower abundantly, whilst its leaves are conspicuous on account of their being fringed at the edges with grey filaments (threads) 2 in. or 3 in. long. The flower spikes attain a height of from 4 ft. to 6 ft. in fine sandy soil or peat, and it is well worth planting in masses in a lawn or in front of a shrubbery. Indeed, we have seen some of the Yuccas grow and flower well in the little forecourts in the most populous parts of London. It is thoroughly hardy, and, apart from its usefulness as a garden plant, it may be employed with advantage in vases in the open air, or in unheated corridors or verandahs.

German Asters Sown in the Open Ground.—Like many more, I have unthinkingly followed the practice of sowing these in a frame, or in pots, and then transplanting them; but I found that the transplanting season, falling as it did, at the busy bedding-out time, was often overlooked and the seedlings neglected. I therefore now sow in the open border where they are to stand, and prick out as they need it. In this way I get good flowers.—N.

Propagation of Japanese Anemones.—Division of the crowns, with roots attached, may suffice when one has a large stock of plants, but to work up a large stock quickly from only a few roots a more expeditious plan is necessary. Three weeks ago, I dug up four old roots of the white variety, and three of the pink; and from those seven plants we have now upwards of 200. This was effected by cutting off as many of the roots as could be spared, still leaving enough to support the main crowns, which were then just starting into growth; the pieces of roots were then cut into

little bits about half-an-inch long, and they were sown in pots of light, sandy soil, just in the way in which we should sow seeds, covered lightly, and plunged in a gentle bottom heat. They started away immediately ; every bit grew, and they are now potted off into small pots. By-and-by they will be planted out, and I expect some of the strongest will flower in the autumn.—E. H.

Carnations, Picotees, and Pinks from Seed.—The middle of March is the best time to sow the seeds of these plants if a little bottom-heat in a cold frame is available ; but they may be grown well from seed sown in pans in the first two weeks of May, and placed in the open ground where they can be sheltered from the midday sun. A light fine soil is most suitable, enriched with old hotbed manure rotted to dust, or old powdery leaf-mould, or a mixture of the two. The seed should be covered with ½ in. of soil; and as every seed should make a plant, the seeds should be lifted separately and sown 1½ in. apart each way, to allow of those that grow most vigorously being removed without disturbing the weaker ones. The soil must be kept moderately moist, but not anything like wet. If the plants are to be grown in beds, these should be prepared while the seeds are springing, and should consist of the same soil as the seed pans, and so arranged that no water can stagnate in them. When the plants have made six or eight leaves. they should be pricked out where they are to bloom, so as to become well established before winter. They require no protection from frost; but if they could be sheltered from excess of wet it would be an advantage. A wet winter with occasional sharp frosts is more dangerous than continuous hard weather. A stock of young plants should be raised every year and planted out every autumn ; and, as a precaution, a few plants should be kept in pots in a dry, sunny, unheated greenhouse during winter, to supply the places of any which may be lost. There are three classes of the Carnation family—Pinks, which are comparatively dwarf in growth ; Carnations proper, and perpetual-flowering Carnations. The last two resemble each other in flowers, both consisting of self-coloured flowers, striped flowers, called flakes and bizarres, and flowers with a ground of one colour and edging of another, called Picotees. The plants which have yellow in their flowers are more tender than the others. Pinks and Carnations flower only once each year. Perpetual Carnations produce a succession of flowers. They are usually regarded as tender, and grown under glass ; but I have never found any but old plants suffer from the winter ; and as they can be propagated earlier than other kinds, and well established before winter, they are perhaps the best for general outdoor cultivation. Carnations do not come very true from seed, and when grown in that way many bad flowers are produced. Everything with feathery or serrated edges should be thrown away, unless very novel in colour. In a perfect show Carnation, the outline should be a perfect circle, and every petal marked alike ; but for garden decoration or cutting such very formal blooms are not so suitable as those which are more varied. The old-fashioned Clove is a self-coloured Carnation, with a powerful spicy odour. The propagation of Carnations and Pinks has already been described in GARDENING.—J. D.

Viscaria cœli rosea.—This is a beautiful hardy annual, sometimes called Agrostemma, which, if sown in autumn in warm sandy soil, and the plants are duly thinned out, will produce compact cushions of rosy-blue-coloured blossoms. It may be sown in spring, but the results will not be so good as those from autumn sowing. Much of the value of annuals is lost through leaving the plants too thick, in which case, instead of each plant developing itself properly, they become a crowded mass.

HOW TO GROW NEAPOLITAN VIOLETS.

FOR small bouquets this Violet is unsurpassed by any other variety, and, although it may be had in flower all through the winter and spring, yet near London market gardeners even do not pay much attention to it, although they grow other kinds by the acre. Single crown runners of it may now be obtained from old plants in abundance ; they should be cut off, and pricked out 1 ft. apart into a half-shady border in good rich soil, keeping them well watered during dry weather, and the ground between the rows clear of weeds by means of the frequent use of the hoe. Towards the middle of the summer a little manure-water may be given them with advantage, but it would be better still to mulch with thoroughly decayed stable manure free from worms. All young runners should be kept picked off as fast as they appear, and in the middle of September, after being well watered, the plants should be lifted with as good balls as possible, and either potted or planted out in a frame previously prepared for them, allowing a space of 3 in. or 4 in. between each plant. The pit or frame should have been filled with fresh stable manure, or, if at hand, Oak leaves are best, inasmuch as they retain a steady temperature for a longer period than other fermenting material. A foot thick of sandy loam and leaf-mould should be placed on the bed in which to set the plants, and after planting a good watering may be given, and the lights closed and shaded for a few days until root action has again commenced, after which abundance of air must be given night and day on every favourable opportunity. Little or no water will be necessary, but if the soil get very dry, the lights should be taken off early in the morning of some fine day, and the water applied in sufficient quantity to soak the whole of the soil, and the plants should be left exposed to sun and air until the foliage has become thoroughly dry. The plants in pots should occupy a similar position to those planted out until they show bloom, when, if they be moved to a light airy shelf near the glass in a cool house, their flowers will open freely. Damp is the greatest enemy which the Neapolitan Violet has when in flower, therefore it is obvious that whilst the roots should be abundantly supplied with water, the foliage should be afforded as much air as possible to ensure its being kept perfectly dry. Red spider often attacks the leaves of Violets during the summer when planted out; and for this there is no remedy equal to that of planting in rich soil in order to keep the plants growing vigorously. When coming into bloom, weak manure-water, in which has been put a little soot, may be advantageously applied at every alternate watering. If the flowers, when picked, be required to travel any great distance, it is best to place them loosely in a small box lined with Ivy leaves, for if tied in bunches, as they often are, they do not last in good condition nearly so long as when placed loosely in the box. C. S.

Viscaria cœli rosea: a hardy annual; flowers rose, shaded blue.

A NATURAL FLOWER GARDEN.

I HAVE in my mind's eye a little lawn in which I think even a landscape painter might take pleasure, so like is it to a natural glade in a forest, where the masses are broad and simple and the flowers quite at home. Here is no staring bedding-out, and no chintz pattern in leaves, but plenty of flowers, both native and foreign, and among them some rare and tender, but yet such as the situation suits ; and they grow so freely and happily, and are so naturally arranged, that it is easy to persuade oneself into the pretty delusion that they are all native to the place, and grew there spontaneously as soon as space was made for them. In fact, the whole place looks quite natural, much as if, while the house was being built in a site selected for its beauty, this pretty little bit had remained on, unruffled and untrodden, and now only asked to be dressed and kept. The turf is soft and deep and springy, such as it is a pleasure to tread on, and on which you may lounge with comfort on a warm sunny day. In early spring it is dotted with flowers, the remnants of which do not suffer from being mown out of the way when the grass first requires the scythe.

On this lawn there is one really large tree : it is a Beech—the weed of the forest, the lady of the woods. There is room for a large family party to rest themselves under its shade. Near the entrance, indeed, there is a miniature wood of very tall trees ; but they have been allowed to grow too near together to make fine specimens. It is too late to thin them now, and they give a pleasant shade ; and with the shrubs and smaller trees, of which there are a great many choice and well-grown examples, they help to give its sylvan character to the sunny opening. Several of the most "sticky" of these tall trees are made quite beautiful by being draped and garlanded with Roses, Honeysuckles, and other climbers. Our woodman appears to have left some noble stumps when he made this clearance They are now covered all over with lovely plants which look as if they came there of themselves, simply because they liked the place. Some rocks or boulders, apparently natural, are obtruding from the ground ; and our woodman seems to have thrown together such big stones as he found in his way. Among them Sedums, Saxifrages, Gentians, and various beautiful alpines, find a home.

Up to the very roots of the trees and shrubs the ground is covered with tender green. No spade-work is visible anywhere. Primroses, Daffodils, Violets, and Cyclamens grow undisturbed in the shade, and nestle against the tree trunks. Considering how little of this beautiful green lawn is broken up for flower beds, it is surprising what numbers of lovely nosegays it constantly produces for the refreshment of the sick and lonely. This is a veritable pleasure-ground. It is not selfishly enjoyed ; and it is not a worry on account of expense.—H.

Begonia lucida as a Wall Plant.—This is a free-growing glossy-leaved species, of rambling habit, but it is one of the most effective plants with which I am acquainted for draping the back walls of warm plant houses or conservatories. It is readily increased by means of cuttings struck in a warm house, and small plants of it introduced here and there on Fern-covered walls soon develop themselves and hang down in bright green wreath-like masses, forming a good contrast to the darker-leaved Ferns and other plants with which they may be associated. It may also be used with good effect as a basket plant.—B.

Tropæolum tricolorum.—A few good plants of this, when in flower in the cool greenhouse, always attract attention. When such plants have done blooming, they should be allowed to gradually dry off. When

they have completely died down, the pots should be laid for a time on their sides under the stage. In autumn they should be again repotted, though sometimes they do well without such attention. Loam, with a small proportion of peat and sand, makes a suitable compost for this plant, the bulbs of which should be set about 2 in. under the surface. When the young shoots begin to grow, care should be taken to well cover the base of the trellis with them. The top of a well-furnished Spruce Fir makes a good support for this plant, provided it has been some time cut; a balloon-shaped trellis is, however, generally used.—M.

FRUIT.

Watering Fruit Trees.—As a general rule, watering young trees in summer does more harm than good, by crusting the surface, without reaching the roots; and even if the roots are reached, the relief is only temporary, unless the watering is regularly repeated. There is a great want of appreciation of the amount of water required for the trees by those who apply this remedy. A young tree 4 ft. or 5 ft. high, if growing well, soon throws out roots several feet on each side. If these roots are only 3 ft. long, the circle of roots will be 6 ft. in diameter, and at a depth of only 1 ft. there would be no less than 37 cubic ft. of earth to saturate with water, requiring for one-fourth the bulk nearly one hogshead for a single watering. It is true that a young tree just planted may have had its roots cut much shorter, but as new ones are to be quickly thrown out into the soil as it commences growth, watering within restricted limits will do but little good. Clean mellow culture and wide and heavy mulchings are better than all the watering that can be given.—E.

Gooseberry Caterpillar.—There is no occasion for experiencing a single day's annoyance on account of this caterpillar. Water the branches affected, and, while wet, sprinkle some freshly-powdered hellebore over them. In a few minutes the grubs will have made themselves scarce, and will not return.—B. H.

Currants Losing their Bloom Buds.—My garden is situated in the heart of a city, and sparrows pick the buds off my Currant and Gooseberry bushes, and also off Plum trees trained against walls. I have tried many so-called remedies to prevent them, but the one that I have used for these last few years I find to be the best and simplest, viz.—after pruning my bushes, I procure some white worsted or knitting cotton, and string it several times from side to side, and once or twice across the bushes, leaving it there. No more sparrows come near them; they seem to me to be afraid that it is a net set for them.—J.

Currants on Walls.—The fruit of these is not often molested by birds whilst they have bushes in the open ground to attack, but when these fail the wall fruit will be in danger, and should be netted at once. By this means a supply of Currants for dessert can be kept up much longer than it otherwise could be; they will hang for many weeks when grown against the walls of buildings or anywhere else under copings. When grown on north, east, or west walls, they come in later than on more sunny aspects, and, if kept dry, will a long succession of useful fruit. Wasps, in some parts of the country, are very numerous in warm seasons, and should be guarded against; a ready and certain method of destroying them is dipping pieces of rag in gas tar, placing them in their holes at night, and setting fire to them, at the same time covering the hole up with earth, so as to prevent the fumes escaping; if this is done effectually, none that are inside will survive; but, as quantities of nests exist that are never found, means must be taken to trap those that molest ripe fruits. Plums, especially Greengages, are their particular favourites: so fond are they of this fruit, they will often attack the crop before it is fully ripe, and unless they are destroyed scarcely any will escape. The most effectual traps are ordinary hand-lights raised on bricks placed near the foot of the trees which they infest; put a few of the fruits which the wasps have partially eaten inside and near the top of the hand-lights, in which there should be an opening 1 in. or 2 in. in diameter, through which the wasps can get; nine wasps out of every ten that are attracted by the fruit-bait, instead of departing at the bottom, where they came in, will rise to the top of the glass and find their way out through the small aperture alluded to; but, to prevent their getting away, another glass, similar in size and shape, and quite tight, must be put on the top of the first; here they will be confined until they die. Wide-mouthed bottles, filled with sweetened beer or treacle and water, hung in the trees, will also catch great numbers of them, and may be employed in addition to the hand-light traps.—A. C.

A Remedy for the Pear Tree Slug.—For several successive summers my Pear trees, both wall and standards, presented a burnt-up appearance—every leaf being as brown as leather; and, later on, all the leaves fell, giving the trees a mid-winter aspect. This was the work of the disgusting-looking and very offensive-smelling Pear-tree slug, which annually made its appearance in great numbers about the 15th of July, not confining itself to the Pear trees, but also attacking adjacent Plum and Cherry trees. I had the trees well dusted with lime, using for the purpose an old-fashioned tin pepper-box. Ten days later they received a second dusting, and evidently a severe lesson had been administered to them, inasmuch as the following summer only a very few made their appearance—so few, indeed, that they were easily destroyed by hand-picking. Last summer I kept a vigilant look-out, and was not able to discover a single one in my garden, while the fruit crop was abundant, fully repaying me for any little trouble to which I had been put.—G. F.

Thinning Stone Fruits.—When a Peach tree sets its fruit thickly, the first thinning should be proceeded with as soon as the fruit is fairly set. Do not delay this work till the fruit is stoned on the plea that the tree is sure to cast a portion of its fruit of its own accord at that critical period, forgetting that exhaustion is the chief cause of a tree dropping its fruit, and that the heavier it is cropped previous to the stoning period the more likely is it to suffer. It is rarely that a Peach tree casts any quantity of its fruit when thinly set. This I have remarked over and over again, and also noticed that the fruit in such cases was always finer, as might be expected; but a healthy good-conditioned tree usually sets an enormous quantity of fruit, frequently fifty times more than it can bring to maturity. Frequently when the weather has been dull and unfavourable at the setting period, a large per-centage of the fruit is imperfect. At the same time that this is cleared away, the healthy fruit should also be thinned out to 1 in. or 2 in. asunder, or more if there be plenty of it; and then thinning may be stayed till the fruit is about the size of small Beans or green Gooseberries, when it should be thinned a third time, leaving the fruit about 4 in. apart all over the tree; after stoning they may again, and for the last time, be reduced to 9 in. or 12 in. apart, according to the vigour of the tree. The amount of space allotted to each Peach is commonly reckoned to be about 1 square foot, and no doubt when fine large fruit is desired this is not too much; but it is more than is usually allowed, and more than is necessary in an ordinary way. I have for years had magnificent Victoria Nectarines from a not very old tree that has always been cropped at the rate of one fruit to every 6 in., as near as could be averaged; but the Victoria is a vigorous grower, and can carry a heavier crop than most other varieties of the Nectarine. On ordinarily vigorous trees 9 in. will, however, be sufficient for general cropping, and at this rate the fruit ought to be of fair size, but not extremely large. Still, moderate-sized fruit in abundance and well finished is preferred for dessert purposes to a scanty supply of large fruit, though the last is undoubtedly the test of high culture. After the thinning has been done, and the trees have been disbudded for the last time, the leaves and shoots should be put aside or pinched wherever there is a fruit, in order to let the light and air play all round it. Shaded fruit is either so large or so well flavoured as that which has been well exposed from the first. If, however, the shoots be trained thin enough to allow the sun's rays to penetrate freely to the wall behind, the fruit will generally have enough light. In conclusion, it may just be stated that the directions here given apply also to all other stone fruits.—C.

Close view of Clematis montana grandiflora on an old Yew tree. (See front page.)

Liquid Manure for Plants in Pots.—The beneficial results obtained from manure-water when judiciously applied to fruiting and flowering plants have long been recognised by cultivators, and its use is now becoming more general. It is well known that the roots of plants are usually more healthy when growing in pure soil free from rank manure, and these roots will draw up more healthy nourishment to the plants from manure given in a liquid state than when they are encased in rank material which they cannot consume. The suc.

cessful florist has more faith in giving stimulants when the plant really needs them than in keeping the roots buried in soil made rich and almost offensive by strong manure. When roots are few, and the plants almost at rest, the purer the soil, and the less stimulant the plants receive, the better will they thrive when their roots come to draw up larger supplies of nourishment. Moisture is needed to soften the soil, and to allow the roots to extract nourishment from it; but when all the virtue is out of the earth, and the plant begins to show signs of distress, all the watering in the world will not give vigour to the exhausted functions; but let a portion of guano or any well-prepared manure be mixed with the water sufficient to colour it, and let this be repeated at every watering instead of giving a much stronger dose at longer intervals, and the result will be most satisfactory. I have tried a number of experiments with liquid-manure, and all lead me to have faith in the application of it, at every watering, in a weakly state. A number of fruit trees in pots (chiefly Plums) which had not been shifted for years, produced heavy crops of fine fruit, and, though there was little in the pots but roots, frequent doses gave them all they required. A number of old Fuchsias were stunted and pot-bound, but pressure of more important matters prevented our potting them into fresh earth; but to each watering a colouring of guano was allowed, and the plants, with their pot-bound roots, have not only made vigorous growth, but flowered freely from June onwards till November. Some Pelargoniums, which were cut down and allowed to break in the usual way, were shaken out of the pots, and placed in smaller ones, but when they should have been shifted they were allowed to remain in the small pots, which were crammed with roots; guano-water was given at all times when they required moisture; the plants grew and made fine foliage, and flowered better than others which were favoured with larger pots and fresh soil. Many other examples I could give to prove that giving liquid manure frequently, and not till roots are in abundance to consume it, is the proper way to deal with this important assistant to cultivation.—*Florist.*

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 10.—Sowing Scorzonera, Salsafy, Radishes, and Early White Snowball Turnip; potting late-struck Coleus and Alternantheras; pricking off Antirrhinums, German and Ten-week Stocks; sticking and earthing up Peas; dusting Turnips and other seeds just coming up with wood-ashes, to keep off the fly; looking over Cucumbers and Melons, stopping them and removing all weak shoots and male blossoms, and fertilising them where required; potting winter-flowering Carnations and Musk; re-potting young Cyclamen plants; planting Seakale thongs, Violets, and more Lettuces; pricking out main crop of Celery into cold frame; digging and raking flower borders not already done; turning walks in flower garden in order to kill weeds and give the gravel a fresh appearance; sticking Peas that are above ground; hoeing among Potatoes, Carrots, Beet, and Herbs, and digging out more Celery trenches.

May 11.—Sowing Green Curled and White Batavian Endive; pricking out Lettuce, Cauliflowers, and Asters; planting out Calceolarias, Pelargoniums, Golden Pyrethrums, and other hardy bedding plants; thinning out Beet and filling up all failures; watering newly planted Cauliflower and Lettuce plants; looking over Peaches, Nectarines, and Apricots on the walls, nailing in the leading shoots, and disbudding them where required; potting and staking old Fuchsias, and shifting Balsams into their flowering pots; potting off Cucumbers; sowing Marjoram, Sweet Basil, Neapolitan Cabbage and Paris White Cos Lettuces; planting Lily of the Valley, tree Carnations, and Anne Boleyn Pinks; also beds of Asparagus; putting in cuttings of Clerodendrons, Aphelandras, and Fuchsias; putting Azaleas in Vinery to make their growth; nailing leading shoots of Apricot and Peach trees out-of-doors; plunging Rhodendrons and Lilacs; raking Rose beds.

May 12.—Potting Cockscombs that are showing bloom; also other kinds of Celosia; potting off small Begonias, and other fine-foliaged plants; sowing Primulas, Cinerarias, Calceolarias and Globe Amarantus; also Mignonette, round Rose trees; planting Sweet Briers, Deutzia scabra, crenata and gracilis, Dicentra spectabilis, and April-sown Lettuce; watering Melons, Violets, and young Celery plants; stopping all shoots on Fig trees; putting Alternantheras for bedding-out in cold pits to harden; earthing up Cauliflowers; keeping Orchard-house rather moist; thinning fruits of Apricots for the first time; tying Peach trees; sowing Giant White Cos and All the Year Round Lettuces; potting Vegetable Marrows and ridge Cucumbers; thinning out Spinach and Turnips; preparing stakes for Dahlias and Hollyhocks; watering Cucumbers, Melons, Potatoes, Carrots, and Beans in frames; looking over Strawberries, and picking off weak and late blooms; putting stakes and strings to Broad Beans and earthing them up.

May 13.—Potting Primulas and a few Fuchsias intended for large specimens; also Phlox Drummondi; sowing Picotees, Mandevillas, Zinnias, Japanese Maize, and Tropæolums of different sorts for baskets; also sowing Cannas, Sweet Peas, Ten-week and Intermediate Stocks, Wallflowers, and Champion of England and Veitch's Perfection Peas; planting Pansies, Lavender, Gladioli, Stocks, and Asters; watering and mulching all Apricot trees; earthing up Vegetable Marrow ridges; potting Standard Chrysanthemums; pulling up spring annuals that have ceased flowering; giving seed-beds a little guano; thinning Carrots and Turnips; putting Castor-oil plants for bedding into cold pits; taking up Tulip and Hyacinth bulbs from flower-beds; potting on Chilies, Cucumbers, and Pelargoniums; planting out Vegetable Marrow plants under hand-lights; picking the dead-leaves off Cauliflowers and giving them a good earthing.

May 14.—Sowing Cardoons, Chervil, Thyme, and Mustard and Cress; potting small Dracænas and Palms; planting early Savoys and Brussels Sprouts; mulching late Strawberries with long chaff cut from stable litter; syringing Rose trees with Quassia-chip water to kill green fly; taking down all wall tree protections, and storing them away; hoeing amongst all growing crops; potting Azaleas, Daturas, and a few large scarlet Pelargoniums for the autumn decoration of the conservatory; potting off seedling Humeas, Portulacas, and Balsams; sowing Amarantus melancholicus and elegantissimus, and pots of Mignonette; hoeing among all growing crops, and staking Peas and Scarlet Runners.

May 15.—Potting off Balsams, Petunias, and Phloxes; planting out Lettuces, Cauliflowers, and Tomato plants; getting all Potatoes earthed up as opportunities occur; thinning out the main crop of Parsnips, Onions, and Carrots; potting Hedychium Gardenianum; sowing Perpetual and Round-leaved Spinach, Broad Windsor Beans, and more Lettuces, Mustard and Cress, and Radishes; planting Sweet Peas raised in pots in well-manured ground; also planting Tritomas, a frame of Sweet Basil, and putting out Cauliflower plants in manured trenches; re-filling and planting flower vases; cutting down Sage plants; clipping Cerastium tomentosum; bedding-out Feverfew, and tying Pelargoniums and Fuchsias; gathering caterpillars from Gooseberry trees; putting all bedding annuals out-of-doors; taking down and stowing away wall tree protections; dusting Carrots with lime and soot.

Glasshouses.

Roof Climbers will now require regular attention to keep them from becoming an entangled mass. Let every means be employed to keep them free from insects, more especially scale. Azaleas that are brought into bloom in other structures for removal to the conservatory will be benefited by sprinklings overhead with the syringe every afternoon until their flowers are fully expanded; they should also be shaded, especially the high-coloured varieties. They must likewise be well attended to with water, as, during the development of their flowers, there is a much greater drain upon the roots than at any other time, and if allowed to become dry the flowers suffer as well as the growth for the ensuing year.

Geraniums and Calceolarias that are throwing up flower trusses should be encouraged by means of liquid manure, not too strong, especially in the case of Geraniums, or it causes them to run too much to leaf. Fumigate regularly, and not too severely. Fuchsias stake, stop, and tie; closely examine them to see that they do not suffer from aphides or red spider, as either quickly spoils them. Cockscombs, Balsams, Achimenes, and Hydrangeas should be well attended to, as these, with the plants previously mentioned, will be the principal things to be depended on during the following two months, when there is much greater scarcity of flowering plants than during early spring.

Abutilons.—These almost incessant flowering plants now exist in such variety, and are so dwarf in habit and free-blooming, that they will flower even in very small pots. Young plants of them potted now and encouraged to make growth will, four months hence, have attained a useful size, keeping them stopped, as occasion may require, in order to lay the foundation for a bushy form, which will, in the majority of cases, be found the most useful. The stopping thus recommended by moving the points of the shoots with the newly-formed undeveloped flower-buds will induce the plants to make growth instead of flowering till they are required. By way of variety, and to assist effective arrangement, a few of them may be grown as standards, dwarf, or of medium-size, according as they may be found most suitable for the description of structure wherein they will have to be used. These plants exist in various shades of colour, from the deepest dark crimson through the paler hues of red down to yellow and white, and the plants are as different in habit as they well can be from the species first introduced.

Single and Double Petunias.—At no season of the year are these so useful as late in summer and autumn; blooming, as they do, in the smallest state, and continuing to flower on up to the end of the year with very little attention, they deserve to be grown in quantity to come in about the time mentioned; they will be found especially serviceable, for when done with all of them can be discarded, excepting a store pot or two of each variety, which should be retained for purposes of propagation—a great advantage, as in winter most of the space allotted to greenhouse subjects is needed for plants of a more permanent character. Cuttings put in a few weeks ago and now rooted—kept three or four together in 6-in. pots in light rich soil, and moved into others 2 in. or 3 in. larger when necessary, keeping them sufficiently stopped to have them compact, and picking the flowers off till within a month or so of the time when they are required in bloom, and the shoots kept in position with a few light sticks and ties—will be most useful. Many of both the double and single sorts are well worth cultivating; the latter, consisting of beautiful and distinct colours, are now raised from seed, and yield an abundant amount of variety. Either the double or single kinds will do for hanging baskets, but the single, being usually of a weaker and more procumbent habit, are better suited for the purpose than the others.

Amarantus and Balsams.—Young plants of the old-fashioned Cockscomb, the small Globe Amarantus, and Balsams should have every attention. They need plenty of light, and root-room sufficient to enable them to get strong and vigorous in their early stages, otherwise their effective appearance when in flower will be much diminished. A few more seeds may now be put in with advantage to produce plants to bloom later on. Little difficulty after this time will be experienced in accomodating all such plants as those just named; for ordinary frames and pits—in which they will grow much better during the summer than in houses—will shortly be at liberty and ready to receive them.

Schizostylis coccinea.—This is another plant that deserves to be grown in considerable quantities by every one who possesses a greenhouse or conservatory. It is one of the finest late-flowering plants which we have out-of-doors, where it can be protected a little; but, when properly treated, it is even more useful for conservatory decoration. It may be managed in two ways—either planted out in rows or clumps in the open ground, in good moderately light soil, that will admit of its being lifted in the autumn for potting without the breakage of root fibres, which inevitably happens when the land is of a heavy, close nature; or it may be grown in pots, six, eight, or a dozen together, according to the size of the pots, which may be from 7 in. to 10 in. in. diameter.

Flower Garden.

All hardy plants should be got in forthwith, and the places marked out and prepared for tender ones, in order that there may be no unnecessary delay as soon as it is safe to plant them; meanwhile continue to propagate Alternantheras, Coleuses, and Iresines, which cannot be planted too thickly together if they are to be effective from the first. Pelargoniums, Lobelias, Petunias, Heliotropes, and similar plants ought now to have full exposure, except on frosty nights, when canvas or mat coverings will be requisite and sufficient. Seedling bedders, such as Ricinus, Wigandia, Solanum, Cannabis, and Ferula, must still have the protection of a cool house or pit, and be afforded plenty of space to induce sturdy growth. As these cannot be planted with safety till the first week in June, if they are likely to get pot-bound they should be at once shifted into larger pots in order that no check may be given to the plants, as that causes premature flowering or fruiting, which, as a matter of course, hinders that noble development of foliage which has made them so popular as easily-raised sub-tropical plants.

Hollyhocks.—If plants propagated in spring are not yet planted out, that should be done at once; they will flower with the Dahlias in September. Plants out and growing should be mulched, but do not water, unless it is absolutely necessary, until the nights are warmer.

Pansies.—We cannot boast much of the growth of plants of these put out into borders; they do not seem to like the dry east wind which has so long prevailed; nevertheless the

plants look healthy, and fortunately are yet free from green fly. Plenty of blooms can now be obtained from plants in pots. See that they do not suffer from want of water, and give manure water at every alternate watering. Air the frame freely and pick off old flowers and leaves as soon as they show signs of decay, and arrange the plants so that they may present a pleasing effect.

Chrysanthemums.—The cold, retarding weather is showing its effect on Chrysanthemums in pots, and they need all the encouragement possible just now. The plants that are at all backward should be placed in the greenhouse, or be kept in a cold frame and somewhat close till they get a good start; the stronger and more forward plants need not be kept so close, but they should be sheltered from cold winds, and on no account be allowed to suffer from want of water. Stopping must be done as required; now is the time to lay the foundation of good blooming plants in the autumn, and vigilance should be the motto of the cultivator.

Clematises.—All are now making a rapid growth, and attention to training is necessary. In conservatories the shoots of the spring-flowering varieties, whether the plants be in pots or trained to walls or pillars, should be so tied in as not to hide the buds that are already expanding; on no account cut away these shoots, as they will yield flowers next spring. The stronger summer-blooming varieties need to be so trained as to fill the space required to be covered; the better the growing shoots are displayed, the finer will be the show of bloom in July. As soon as hot dry weather sets in, mulch with manure, and give occasional waterings with manure water.

Dahlias.—The young-struck plants should be potted on as required, and kept in a frame to make growth. It is scarcely safe to plant out till the first week in June, and that gives the plants time to grow to a good size and become well hardened. The dwarfer and more bushy the growth in the young plants, the better are they for planting out. The ground intended to be planted with Dahlias should be trenched and a good dressing of manure applied.

Daisies.—Beds of double Daisies are now in the full flush of their beauty, and their effectiveness is prolonged if the beds be occasionally examined and the dead flowers removed. This facilitates a succession of bloom, besides tending to keep the beds smart in appearance. The new variegated White Globe should be made a note of for use next spring; it is very fine indeed, and is superior to all the variegated forms bearing white flowers.

Delphiniums.—Strong plants which have been in the ground all the winter will now be greatly aided in their growth if the soil be loosened about them and receive a mulching of short manure and leaves. A bed of the finer varieties should now be made; and this will be found an effective manner of growing these fine perennials, as it enables the several kinds to be compared the more readily. A deep loam well enriched with manure and leaf-mould makes an admirable bed, and as the plants come into flower, they are materially assisted by a surface mulching of manure. There are now a number of beautiful new varieties well deserving cultivation.

Pyrethrums.—These fine hardy decorative plants are commencing to grow, and as snails and slugs are apt to eat the foliage, they should be looked after, The enjoyment of all such plants is enhanced by having a bed filled with various sorts, and now is a good time to make one. Those who have limited garden space might grow a few Pyrethrums in pots; they are easily managed, and are well suited to a cold greenhouse. It is a mistake to overpot them; in fact, many plants are thereby spoiled.

Polyanthus.—Choice varieties in the open ground will be greatly benefited by having the flower-stems removed, adding a top-dressing of some good soil. Any good varieties in pots may be ranged under a north wall on an ash bottom, or planted out in a prepared bed for the summer. The Gold-laced varieties, being much later, are now in full bloom. The named kinds are of somewhat delicate constitution and need special treatment. To yield good flowers they should be well established in pots; and when they have ceased flowering they also can be planted out. Those potted in the spring should remain in the pots all the summer, and be kept in a cool moist place. In saving seed from any particular variety, be content with two or three pods, and do not exhaust the plants by overtaxing their energies. A sowing may be made as soon as the seed is sufficiently ripe.

Hardy Fruit.

Unremitting attention will now be requisite to ward off the attacks of aphides from outdoor fruit trees; for if once these pests get a thorough hold upon the trees all hopes of fruit that is fit either to be seen or eaten are at an end, and the crop of next year is also endangered. Tobacco powder or snuff, applied through a flour-dredger, is the best remedy till the fruit is set; but afterwards frequent washing with clear water will keep down all kinds of insects and prove beneficial in a variety of ways. It should be applied with a certain amount of force, as through a syringe, garden engine, or hose. Keep a sharp look-out for grubs on Apricots and caterpillars on Gooseberry bushes, and as there is no remedy so effectual as hand-picking, let it be done at once. Pears, Peaches, and Apricots that have set their fruit thickly should be thinned out as soon as it can be seen which fruits are likely to swell best. As to thinning, it is very difficult to give precise directions, for experience alone must teach how thin they ought to be, or how many or much fruit a given tree is capable of bringing to perfection. Quality rather than quantity should be aimed at in fruit culture; certainly one large and well-flavoured Pear, Peach, or Apricot is preferable to two small ones, and especially with the two latter kinds, the stones of which are a consideration. When thinning, the guiding principle should be to have each fruit clear of its neighbour, evenly distributed over the tree, and fully exposed to sun, air, and light. Young recently-planted trees will require to have the shoots regulated and pinched, trained, or tied into the form they are to assume, in doing which care should be exercised to have the tree equally balanced, that the flow of sap may be alike over all parts. Any shoots that manifest a tendency to grow stronger than the rest may be checked by bending them downwards and keeping the lateral growths closely pinched off; but weak shoots should be allowed to retain all lateral growths made, at least for a considerable period. Canker and gum are the inevitable consequences of too tight ligatures and injury from nails, or bruises in other ways, all of which should be guarded against. Strawberries have made rapid progress during the last few days, and are now throwing up their flower-stems. If it has not yet been done, a mulching of long litter should be applied to them, for the double purpose of keeping the fruit clean at ripening time and to prevent the too rapid evaporation of moisture.

Vegetables.

The principal crop of Beetroot may now be sown, and as this is a deep-rooting plant, the ground should be deeply dug and well pulverised. The latter operation is essential for the generality of crops, and for none more so than those that penetrate deeply into the soil and are of a bulbous or tuberous rooted character. The seeds of this vegetable not suffering from the attacks of birds or insects, like many others, do not require sowing so thickly; but sufficient seed must be put in to secure a crop without having resort to fillling up blanks by planting; for, although Beet will succeed when thus treated, yet it entails more trouble, and in dry localities in a hot season these plants do not root so freely as some others. Plant out Lettuces that have been sown in the open air as soon as they are large enough to handle; if they are removed to where they are to grow when the leaves are 1½ in. long, they suffer much less than if allowed to get larger before removal. Upon this, in a great measure, depends their ability to stand long without running to seed; much also depends upon their receiving plenty of water until they have taken a firm hold of the soil. Hoe and stick Peas as soon as they are large enough, and keep the soil well drawn up to the stems of Cabbages or Cauliflowers, or they may suffer from the wind, especially in exposed situations. As Potatoes make their appearance above ground draw the soil well up to them so as to protect them from the slight frosts that are liable to occur. Potatoes that are planted at the foot of south walls will be much benefited by an occasional soaking with water.

GLASSHOUSES AND FRAMES.

Bulbs in Winter.—I have noticed complaints that hardy bulbs have not flowered satisfactorily this year. Now, my experience is quite to the contrary. I had from one to two dozen of each of the following in a cold greenhouse (frost excluded by a paraffin vaporising lamp, price about 30s.; sometimes two were required, greenhouse being 20 ft. by 8 ft.), which flowered without a single failure in February and March, planted in pots, pans, and boxes. It may be useful to remark that the bulbs never left the greenhouse, were planted in October, and placed under the stage till they showed above the surface soil of the pots (being watered very occasionally), then placed on the stage, where they flowered:—Double Snowdrops; Crocus Sir Walter Scott, Elfride, Imperati; Roman Hyacinth, (blue and white); Polyanthus Narcissus (paper-white); Roman gloriosa; Scilla bifolia, S. sibirica; Hyacinth (blue), grape large; Tulips (early double and single); Jonquils (single sweet-scented); Dog's-tooth Violet; Hoop Petticoat Narcissus. I also flowered the following in Jan. and Feb.:—Saxifraga Rocheliana, S. Wallacei; Anemone stellata; Viola White Czar; my one failure was Tritelia uniflora—they never started. Bulbs of same sort, and many others, have been and are flowering well in kitchen garden border—notably Iris reticulata in early March. Soil is light sand, well enriched with manure; been lately a field; climate, decidedly moist.—ALICE F. MALCOLM, *Achnamara, Argyleshire.*

Lilies.—Nothing is more useful for conservatory and greenhouse decoration than the autumn-blooming species of these plants, for which purpose, independently of their other merits, they deserve special attention. If amongst plants of Lilium auratum a few exhibiting a disposition to bloom later than the others be picked out and marked, they can, without any undue amount of retarding, be made most serviceable for the decoration of the greenhouse and conservatory in autumn. Then there are all the different varieties of L. speciosum that may by similar treatment be induced to come in at the same time. If a portion of the plants be now put at the north side of a wall, but not too much shaded or treated so as to chill them, until the weather gets warmer, they will afford a succession of flower after those more fully exposed to the sun are over.

Tuberous-rooted Begonias. — For blooming through the autumn months a good number of these should be grown, selecting those that are the most distinct in colour. They should acquire a useful flowering size, and if small-blooming bulbs be now at hand in 3-in. or 4-in. pots, keep them growing until towards the end of the month, when they may be turned out in a full open situation in light free soil, with just as much support in the shape of sticks and ties as the particular habit of individual plants are found to require. They should be well attended to with water, transferred to pots at the beginning of September, and kept at a little above an ordinary greenhouse temperature Thus treated, they will bloom satisfactorily. Where a sufficient number of larger plants exist, they may be kept in pots proportionate to their size, placed for a few weeks in a pit or fram and then have their pots plunged out-of-doors, stopping them once or twice during the season to induce a close enough habit, and they will keep up a complete mass of flowers through the autumn. For general decorative purposes some of the less perfectly-formed flowers, from the florist's point of view—that is, those that have longer narrower petals—are more effective, and have a more elegant appearance than the rigid, stouter-growing kinds.

Primula cortusoides amœna.—This Primula is one of the easiest to cultivate. It should be grown in pots, large or small according to the size of the plants, in a mixture consisting of two-thirds rich loam and equal quantities of well-rotted manure and leaf-mould, adding a small portion of sand. Pot them immediately after they have flowered and place

them on a bed of ashes, giving them plenty of water. They are greatly assisted by being fed during their growing and flowering seasons with a little weak liquid manure. Winter them in a cold frame, giving them abundance of air except during severe frost, and under this treatment you will get both good foliage and flowers. We saw a fine display of them the other day, in Mr. Dean's Nursery, at Bedfont, where are also many fine varieties with lacinated blossoms of a very bright colour.

Ornamenting Greenhouse Walls.—Where climbers are trained on greenhouse walls there are often spaces which might be made ornamental by the introduction of a few bracket plants: and even when climbers completely cover the walls, such an arrangement as the one shown in our engraving, which was made from nature in Mr. Williams's nursery at Holloway, would greatly add to the effect of the house. The engraving in question represents a pocket made of virgin cork, into which may be put a few handfuls of soil, and in this is planted a fern such as Nephrolepis exaltata, round the base of which may be planted Isolepis gracilis, Ficus repens, or any other plant with a light pendulous habit of growth.

The Australian Bird's-nest Fern.—This is a fine Fern for a stove or warm greenhouse. Its fronds attain under good culture a length of from 4 ft. to 6 ft., and they are often 6 in. or more in breadth. The young fronds are of a delicate pea-green colour, very glossy and

Australian Bird's-nest Fern (Asplenium Nidus avis).

effective. It grows well in turfy loam and leaf-mould, with a liberal addition of broken bricks or old flower-pots and a little charcoal. It needs plenty of water when growing freely, and it makes a good exhibition plant. Its name is Asplenium Nidus avis.

ANSWERS TO QUERIES.

1954.—**Constructing a Fernery.**—If the sides require simply covering from top to bottom with virgin cork, the readiest method will be to board the three walls with any kind of old wood on which to nail it. Get thinnish pieces of cork, as they are easier to fasten and lie flatter. Those that are thick, or bent so that they represent half a tree trunk, must be sawn down the back with a tenon-saw, leaving them thin enough for the nails to bite well in the wood after piercing the cork. A nail driven through the centre of those pieces slightly semi-circular will bring it flatter with the boarding, and render it easier to fit other pieces. The spaces between the larger pieces may be neatly filled up by breaking bits off a large thin piece, and cutting with a pocket knife to fit. With a little care, this can be done so that the joints are imperceptible. After covering the walls, the effect may be further enhanced by making small brackets, on which to place pots, either of flowers or Ferns, covering the front of the framework with cork, which hides the pot and shows only foliage and flowers against the background of cork. If these brackets are arranged in tiers, they will give a picturesque effect. This can be easily done by simply having two or three narrow shelves, according to space, nailing cork to the fronts. In this case, the cork on the wall need only commence above the highest of the shelves, but all should be so arranged that no woodwork is visible. Places may be made here and there in the rockwork, near the roof, to hold a small pot containing a creeper of some kind, or Moss or Fern, at pleasure; these add to the beauty of the whole and give a more romantic appearance to the rocks. A fountain might be made either in one corner, the middle of one side, or the centre of the Fernery. If in either of the two former positions, a little cascade falling into the tank at foot, in which are a few gold and silver fish, might be added with effect. If in the centre, then a jet of water rising from a bowl or tank of zinc will suffice. The fixing a fountain is by no means a difficulty if there is a supply of water at hand. —HY. BENTLEY.

2030.—**How to Arrange a Garden with Flowers.**—Perhaps the best arrangement for the space named would be to make a centre walk 6 ft. long and 3 ft. wide, beginning at the bottom of the garden, and two side walks, 3 ft. wide' 3 ft. long, and 3 ft. from the side fences, beginning at the end nearest the house; then join these three walks by two slanting ones, also 3 ft. wide, so as to divide the garden into a wedge-shaped centre bed, and two somewhat leg-of-mutton-shaped side beds. An edging of ornamental tiles is most suitable for a small garden, and any dwarf plants which can be purchased may be planted next it, such as Echeveria secunda glauca or the very dwarf Lobelia named pumila compacta. Next these may be placed Golden Feather Pyrethrum and Amarantus melancholicus ruber. Next to these, towards the centre of the beds, may be planted any Petunias which can be purchased; and the centre of the triangular bed may be filled with Geraniums, Pentstemons, or Asters; all these plants are procurable in a state fit to be planted out at once. Climbing Tropæolums may still be sown with success to cover the fences, so also may Convolvulus major. The double Clarkias are very showy annuals, about 18 in. high. Coreopsis, 2 ft. high, may still be sown, also Helichrysum compositum and the dwarf Nasturtiums; Tom Thumb King, King Theodore, Crystal Palace Gem, Pearl, and Ruby King are good sorts. Marvel of Peru, already started in pots, would do duty for shrubs for the first summer.—J. D.

1958.—**Treatment of Vallottas.**—Pot them off at once into small pots in a compost of half loam and peat. Keep them for a time rather close until they become well established, when they should get a free circulation of air on all favourable occasions, and be freely watered in hot weather. A light airy greenhouse or a frame is the best place for them during the summer months. The following spring shift into 4½-in. pots, and treat as before; the next year they will bloom freely.—J. C. B.

1913.—**Pruning Coronillas and Genistas.**—Prune back the Genistas immediately after flowering. It is not desirable to cut them in very hard unless the plants have become very leggy and ugly, in which case they may be pruned back to the bare old wood. If the plants are fairly compact, leave about 2 in. of the previous season's growth. Keep them on the side of dryness until the new shoots are fairly formed. As soon as the latter are about 1 in. in length shift into the next sized pot. Keep rather close for a time, water freely when fairly established, and place in a sheltered spot in the open air about the latter end of August, at which time occasional watering with soot water will prove beneficial. This treatment will result in the formation of strong wood and healthy foliage, such plants blooming with great freedom in the spring. Coronillas need but little pruning; merely shortening back the flowering shoots will suffice for them. In other respects they may be treated in the manner recommended for Genistas.—J. C.

1966.—**Sowing Seeds of Coniters.**—Sow the seed at once in pans in a compost of leaf-mould and loam in equal proportions. Place the pans in a frame, if possible with a north aspect; maintain the soil in a moist condition, but avoid heavy waterings, and shade from the sun. As soon as the seedlings appear inure them to full exposure, allowing them to remain undisturbed until the flowering year, when they may be planted out in the open ground.—C.

2062.—**Cottagers' Flower Shows.**—Success lies in distributing the prizes over as large an area as possible, so that half the competitors get at any rate something. The prizes must therefore be numerous, and, unless your purse is a long one, small in amount. You wish to encourage the unsuccessful. To this end, restrict the number of prizes that can fall to a single competitor; otherwise a few enterprising men will keep all in their own hands. Each competitor has a number given him, of which a list is kept; and these numbers, and not his name, are appended to the several articles exhibited. This obviates the suspicion of unfairness. The first week in September is about the best time. Have two judges; two strings to the bow are useful; and an amateur and a professional will correct one another's deficiencies.—H. W. T.

2038.—**Glazing Without Putty.**—Herewith are particulars of my greenhouse:—Shape, semi-span; length, 18 ft.; width, 10 ft.; front wall, 3 ft. 6 in.; back wall, 6 ft. 6 in., against which is a shed containing potting bench, stoke-hole, &c.; angles of roof about 40°; aspect nearly south; heated with saddle boiler and 4-in. hotwater-pipes; contains five rafters, including ends 4½ ft. by 2 ft. (a batten sawn in half); and the horizontal rafters are about 2 ft. 2 in. (a batten sawn in four), which are let into the principal rafters about 1 in., and securely fastened; the glass is 22 in. by 14 in., each pane of which is fastened by two copper clips about 3½ in. long, nailed on the rafters, and bent over at the bottom, which very effectually secures them. All through the past winter I have had no difficulty in maintaining a temperature of 50°; and close by me there is a range of seven large span-roofed houses, heated by one boiler, and which are built on the same principle, in which are grown Palms, Dracænas, exotic Ferns, &c., and such like plants, to meet the requirements of a West-end decorator florist; so "J. T." can rest assured such houses are suitable for forcing.—H. S. HALL.

2033.—**Large Wellingtonia gigantea.**—"Tasmanian" is wrong in supposing that the Wellingtonia gigantea exhibited at the Crystal Palace came from Australia. It is well known as the Mammoth Tree of California, of which it is a native. It was first discovered near the sources of the Stanislaus and San Antonio rivers, in a grove now known as the Mammoth-tree Grove, about 4590 ft. above the level of the sea, in long. 120° 10' W., lat., 38° N. The specimen referred to was known as the "Mother of the Forest," the bark of which was taken off to the height of 116 ft., and brought to the Crystal Palace about 1856, and was burned at the fire which occured at the close of 1866. It measured 357 ft. in height and 96 ft. in circumference, while the bark was about 18 in. thick. Another specimen was 450 ft. in height, and 116 ft. in circumference, and valued at £6250 at a penny per square foot of inch deal.—M. CUTHBERTSON.

2041.—**Culture of Double Primroses in Pots.**—Beyond the difficulties incidental to the growth of all kinds of plants near London, there should be no special difficulty in growing double Primroses in pots. We have seen them well done in 5-in. pots within a few miles of Charing Cross, being simply potted very firmly in good turfy loam and a fair proportion of rotten manure well mixed. At all times of the year a

cool frame with a north aspect is the best place, although the aspect is of less consequence in the winter months. The great secret in double Primrose culture is to keep the plants cool and the foliage fresh. Such common kinds as the lilac, white, and sulphur, will grow almost anywhere; but the crimson, purple, rose, and giant yellows are more chary, and want special attention. It is found to be a good plan to divide the plants as soon as the bloom is over, and repot into smaller pots, keeping the plants shaded for a few days.—A.

2032.—**Carnations, Picotees, and Pinks.**—It is now an excellent time to sow Carnation, Pink, and Picotee seed. As a rule, it will germinate as freely in the open ground as Sweet William or any other Dianthus seed; but, of course, seed of choice things are best sown in pans or shallow boxes under glass. These seeds will come well, if good, in a cold frame or greenhouse, and better probably than with bottom-heat, as the seedlings will be more robust. When the young plants are strong enough, they should be pricked out thinly into other pans, and later on from these into the open ground where they are to flower.—A. D.

1957.—**Treatment of Hoya Carnosa.**—This plant thrives best and flowers most freely when planted out in a bed of good peat and loam of equal proportions. If a back wall exists in the structure, or pillars or supports of any kind, the plants may be trained to them. Where convenience does not exist for planting them out, they may be grown along for a season until well established in 6-in. pots. The following spring prepare some 10-in. pots for their reception, draining them well and covering the drainage with some Cocoa-nut fibre or fibrous peat. The compost should be lumpy and well sanded, pressing it firmly round the old ball. The plants may then be placed in any desired position, there to remain, not needing to be shifted for years. During summer the Hoya delights in a moist atmosphere, and when the pots become well filled with roots, frequent supplies of water will be needed. An annual top-dressing of some artificial manure will also prove beneficial. Although this Hoya is best adapted for covering spare pieces of wall, or clothing pillars in warm houses, it may also be grown in the form of a specimen. All that is necessary when shifting it into a large pot is to place some stakes round the edge of the pot and train the shoots to them.—J. C., *Byfleet.*

1915.—**Greenhouse in the Engine-room.**—We presume that the structure in question will be maintained at an equable temperature during the winter months. An average temperature of 50° to 55° would suffice to maintain in health a number of fine-foliaged plants, and would suffice for forwarding into bloom such flowering subjects as bloom during the spring months. Amongst plants distinguished for leaf beauty may be mentioned Dracænas rubra, congesta, indivisa, ferræa, and terminalis; Aspidistra lurida variegata, Grevillea robusta, and such Palms as Corypha australis, Chamærops excelsa, Rhapis flabelliformis, Latania borbonica, and Areca lutescens. Intermixed with these may be such fine-growing Ferns as Asplenium bulbiferum, Pteris arguta and serrulata, and Adiantums formosum and cuneatum. The great point to observe in the culture of these foliaged plants in such places is to maintain the functions of the plants in a healthy state by frequently sponging both the upper and under surfaces of the leaves. It is also indispensable that they be guarded against hot sun; and if no other means exist, the glass must be sprinkled with whitewash. A portion of the roof should, however, be kept quite clean, in order to accommodate such light-loving subjects as Pelargoniums and succulents of various kinds. During the summer months all the ordinary soft-wooded flowering plants should thrive therein; and annuals of various kinds, such as Mignonette, Rhodanthes, Godetias, Browallias elata and Roezli, and Balsams, may be sown early in the year. Petunias may also be sown in the spring, and make excellent subjects for hanging baskets, especially when used in combination with other flowering plants A nice Fuchsia in the centre, for instance, with Petunias and Lobelias, and a plant or two of Iresine Lindeni makes a very pretty and effective basket. Other good plants for hanging baskets consist of Russellia juncea, Saxifraga tomentosa, Dracæna vivipara, and such Ferns as Goniophlebium subauriculatum and Woodwardia radicans. Primulas sown in the spring may be grown along to flower during the winter months; and young plants of Cyclamen persicum potted now will come into bloom at the same time. In early spring a few Roses, Spiræa japonica, Deutzias, and bulbs of various kinds may be brought along; and we would also recommend the culture of a few such winter-flowering Begonias as Ingrami, manicata, nitida, sanguinea, Weltoniensis, &c. As climbing plants for training up the roof, nothing is prettier than the variegated Cobœa, the variegation of which remains ever fresh and constant, and which requires but a limited root accommodation. There are also Passifloras, Tacsonias, and Maréchal Niel Rose, which may be utilised in a like manner. There is, however, one important point which must not be neglected, viz., the making provision for a free supply of air during the summer months. Ventilators should be placed at frequent intervals in the roof, and, if possible, a few wooden flaps should be let into the side brickwork.—J. C., *Byfleet.*

1961.—**Mixed Houses of Plants.**—A temperature of from 45° to 50° by day, and

Bracket of Ferns and Grasses.

anything under freezing at night, will suit most kinds of soft-wooded bedding plants. Tuberous-rooted Begonias may be wintered at the same temperature; but Bouvardias need, in order to flower them, a constant and regular warmth. No success would attend the attempt to grow winter-flowering or any other kind of Orchids with Heaths, Violas, &c., which need a constant free circulation of air around them in favourable weather, whereas Orchids require a close, semi-saturated atmosphere. To grow cool Orchids well they must have a structure devoted to them, where the proper atmospheric conditions can be maintained. There are, however, many kinds of plants, such as Ferns and foliage plants, which will thrive in their company, and would help to give variety. With the exception of Orchids, all the plants enumerated may he wintered at the temperature above given; but free ventilation must be given in mild weather. For whilst such things as Camellias, Roses, &c., might be forwarded by keeping them rather close, such treatment would prove inimical to the welfare of Geraniums, Heaths, &c.—J. C.

1927.—**Gardening in London.**—If the situation is at all open to the sun's influence annuals of many kinds may be sown during the next six weeks. For present sowing there are Clarkias, Godetias, Collinsias, Calliopsis, Candy-tuft, Leptosiphon; and in May, Tom Thumb Nasturtiums, Scarlet Linum, and Convolvulus Minor may be sown. Geraniums, Calceolarias, Lobelias, and Petunias may be planted out in the latter end of May, thus maintaining a show of bloom throughout the summer months. A dozen or so Chrysanthemums planted now in good soil would prove a satisfactory investment, inasmuch as they thrive in the London climate and bloom when bloom is scarce. If there is an existing wall, plant against and train them to it. We would also try some of the bedding Violas, and some of the varieties of Viola cornuta, seeds of which may be bought at a moderate price. Success will entirely depend upon the aspect and general situation of the plot of ground. The best way is to try plenty of plants, and reject those which do not flourish. In the course of one or two seasons sufficient experience will be gained to render the work of selection an easy matter.—C.

1931.—**Varieties of Chrysanthemums.**—The twelve best varieties are:—Incurved: George Glenny, Venus, Mrs. George Rundle, Lady Slade, Eve, Mrs. Sharp, Miss Hope, Mrs. Dixon, Her Majesty, Pink Perfection, Areginas, Lady Talfourd. Pompones: Princess Matilda, Mr. Astie, Madame Montells, Astrea, Little Beauty, Mrs. Dix, White Cedonulli, Aigle d'Or.—J. H.

1922.—**Propagating Aralia Veitchi.**—Aralias of the Veitchi type are mostly propagated by means of cuttings of the previous season's growth, taken off in the early months of the year. With two eyes only inserted singly in small pots in sandy fibrous peat, and placed in a glass case or under a bell-glass in a warm structure, provided with the special accommodation in the way of bottom-heat. The soil should be maintained in a moist condition, avoiding heavy waterings, and the pots must be plunged up to the rims in ashes, Cocoa-nut fibre, or tan. If the bottom-heat is supplied by means of hot-water pipes, great care must be taken not to unduly heat them, or there is a danger of injnry resulting to that portion of the cutting from whence roots should be emitted. Every morning the glass should be removed for an hour, and the greatest care must be taken to shade them from hot sun. To ensure success in the propagation of this tribe of plants, much watchful care and some experience are necessary.—B.

1986.—**Growing Watercress.**—You can grow Watercress from October to February in a cold frame. Put cuttings in and keep them well syringed; cover with mats during hard frost. Or you can grow them in the overflow from a well. For making a bed, get some clay and soil mixed, level it down, and beat it well with the spade. Make the bed rather high at the bottom end, so that the water will run slowly off. Get some cuttings and plant them, and you will soon have Watercress: or put some cuttings in pots and keep them standing in saucers full of water; syringe often overhead. In this way you can grow Watercresses in the greenhouse.—J. H.

—— Get a pan about 8 in. wide and 9 in. deep, perforated at the bottom. Half fill with old mortar, lumps of chalk, and broken bricks about the size of one's fist. Lay a little Moss on these, and heap up a good body of rich soil on top, pressed firmly down so as to have a convex shape. Then dibble in all over the soil about 3 in. or 4 in. apart, very small cuttings of Cress. Stand the pot in a pan of water; 3 in. of water is sufficient. Smaller pots may be used, but this size is the best. Rough lumps of chalk and old mortar are indispensable. The pan should not be wholly immersed in water.—C. HARXUROT.

1935.—**Tree Carnations and Picotees.**—Those who grow the Tree Carnation extensively make a point of striking cuttings every year, discarding the old plants; this, however, necessitates the accommodation of a warm house or propagating-pit in the early part of the season. Small growers, however, not possessing this convenience may retain their old specimens, and with careful treatment such plants may be induced to flower freely. As soon as the plants have done blooming, train them out into a sunny situation in the open air, attend carefully to the watering, and about the beginning of July shift them into the next sized pot in a compost of two-thirds turfy loam and one-third leaf-mould, adding thereto some silver sand. Drain the

pots well, place a little Moss on the crocks, and a pinch of soot on the Moss to prevent the entry of worms. By no means use manure of any description, but water when the pots get full of roots with soot water. Place one or more neat stakes to each plant and train the shoots to them. Should mildew appear, which may readily be perceived by the flour-like appearance of the leaves, dust immediately with sulphur, and for green fly dust with Pooley's Tobacco Powder. By the end of September place under cover, but ventilate freely. The buds being then formed, will gradually extend in a cold greenhouse during the winter and early spring months. The same treatment will suit Picotees. Suitable soil in small quantities may be had of from any good nursery.—J. C. B.

1999.—**How to Earth up Crops.**—After loosening the earth between the rows with a fork, take the hoe; standing outside the first row, draw the earth up to the inside of it; next draw the earth up to the inside of the second row; turn round, and do the outside of the first row; then the inside of the third; the outside of the second, and so on. This leaves no footmarks, and requires no subsequent raking. Two positions may be tried while earthing up. Stand directly facing the row the other side of which is being done, both feet being in one space; or stand somewhat sideways to the rows, one foot in each of two spaces, the feet parallel to the rows. When working along any space for the first time, strike the hoe in a little beyond the centre of the space. When in the same space again, strike the hoe a very little into the back of the earth drawn to the other row. I have seen crops very neatly earthed up with the spade.—PED.

2034.—**Graveyard Gardens.**—The drip from a Yew tree, or, indeed, from any tree, must of necessity be very detrimental to flowers or plants of any kind on a grave, and it is most improbable that any plants could be expected to produce flowers that would be at all pleasing or satisfactory. If a bright appearance was desired, it would be absolutely necessary to continually furnish the grave with flowers in pots, but that would be troublesome and costly. The best arrangement probably would be to cover the grave garden with carpet plants, such as Sedum lividum and glaucum, and Veronica repens, and plant Echeverias, Pachyphytums, Sempervivums, &c., as dot plants. These would be but slightly affected by drip or shade.—D.

1960.—**Culture of Sunflowers.**—The common Sunflower is a hardy annual, or rather is treated as such; and the seed may be raised easily if sown in pots or pans and placed in a window, frame, or greenhouse, but will germinate all the more rapidly if a little bottom-heat be given. When the plants are a few inches high, they should be pricked out into a frame and protected from snails, and be put out into the open ground when well hardened and strong. Sunflowers will thrive well in any good garden soil, the size of the flowers being large or small as the ground varies in quality. In exposed places the plants should have some support.—D.

2042.—**Pansies for Exhibition.**—The first thing to do in growing Pansies for the purpose of exhibiting them is to obtain young or newly-struck plants in pots, of good named varieties, as, unless good sorts are obtained to start with, all labour will be thrown away. Pansies are divided into two sections—the show or English kinds, and the Fancy or Belgian kinds. The first comprise five divisions, as under:—white, yellow, and purple, selfs and white and yellow ground belted Pansies. The self kinds must be of clear decided colours, and a black and well defined blotch under the eye; the belted kinds have a ground of white or yellow, also with centre blotch, and a broad margin of bronzy-red, chestnut, purple, crimson, or some other hue, and the colours must be in all cases dense, and the margins very distinctly defined. All these flowers should be rounded, of good form, and stout of petal; also of good size, but great size is of less importance in an exhibition flower than perfection or quality in the markings. The Belgian or fancy Pansies are remarkable for the strange and almost gorgeous variety of their colours, and many of the blooms are of unusual size. A correct fancy Pansy should have a very large deep-coloured blotch, covering nearly the whole of the bottom petal and portions of the side petals; and the other portion of the flower may be white, yellow, buff, red, maroon, purple, crimson, and various other shades, but none so dense as the black hue of the centre blotch; some also are flaked or parti-coloured, but all good ones are singularly showy and beautiful beyond the imagination of those who know Pansies only by what they have seen of common strains. Plants struck from cuttings in the autumn can now be had of all the best of these kinds in small pots, at prices varying from 8s. to 12s. per dozen; and a selection left to the florist, according to price to be paid, will be certain to give good variety and fine kinds. If grown in pots these plants should, when obtained, be shifted into 6-in. pots, and in soil that is composed of good turfy loam, well-rotted manure, and a sprinkling of silver-sand; the plants well down, and the points pinched out to induce breaking at the sides. These shoots should be pegged down into the soil when large enough, and as the pots fill with roots some weak manure-water may be applied with advantage. A cool frame shaded from the sun, and facing north, giving plenty of air, is the best place in which to grow pot Pansies. Similar plants may be planted out in a bed well prepared, the soil deeply trenched and heavily dressed with rotten manure forked in on the surface; the plants put out about 12 in. apart each way, and the side shoots pegged down as advised for pot culture. A top-dressing of rotten manure and Cocoa-fibre refuse will help the plants, and in hot sunshine they should be shaded.—A. D.

1962.—**To Make a Garden Pay.**—No considerable profit can be made by growing common fruit and vegetables on one-third of an acre, especially in an unfavourable season, such as last year. It can only be done by producing the finest and choicest articles at the earliest possible season, so as to command fancy prices. I have three quarters of an acre, and sell what my family do not want. I have found Kidney Beans, Celery, choice Raspberries, Daisies, and Polyanthuses, among the most profitable things to grow.—F. T. W.

2040.—**Gladioli for Succession.**—The following are early-blooming kinds, and should be planted between December and March:—cardinalis, bright scarlet; Colvilli albus, pure white; luricans, orange-scarlet; insignis, rich scarlet; and Washington, bright rose-lilac. The autumn-flowering varieties should not be planted before the middle of March, deferring the planting until the middle of April where the soil is of a heavy retentive nature. The undermentioned are some of the best in this class. La Candeur, white; Le Vesuve, intense scarlet; Maréchal Vaillant, brilliant scarlet; Ophir, dark yellow; Benvenuto, orange-red; Belle Gabrielle, lilac-rose; and Edith D'Ombrain, white ground suffused with carmine.—B.

2043.—**Large Flowering Cactus.**—The faded leaves are in all probability the result of imperfect root action. When the plant has finished blooming, turn it out of the pot; examine the drainage, which will probably be found defective, in which case take another pot of the same size, drain it well, and, having worked away carefully with a pointed stick as much of the old soil as possible from the ball, so that a little fresh fine well-sanded compost may be gently worked down between it and the sides of the pot, place the plant in an airy sunny situation, and water only when quite dry.—C. B.

2044.—**Shrubs under Trees.**—We think that nothing would be so likely to answer the purpose as Holly, which thrives very well in shady situations. Many kinds of evergreens, such as Yew, Laurels, Rhododendrons, Box, and Berberis aquifolium, grow very well under trees, but it is necessary that in planting a good start should be given them by well preparing the soil for their reception, otherwise they fail to attain the vigour necessary to enable them to make satisfactory progress under such comparatively adverse circumstances. It must be remembered that the soil everywhere in the vicinity of trees is full of their fibres, consequently becomes very dry in the summer, and is to a great extent impoverished. Therefore, in forming a Holly hedge a trench quite 2 ft. deep must be taken out, mixing with the excavated soil some good manure, and filling in again. In ground thus prepared, especially if the plants are well watered in hot weather, an abundance of fibre will be formed, which, providing the desired amount of nutriment, will cause the plants to make a vigorous growth. Now is a good time to plant.—J. C. B.

2056.—**New Zealand Flax.**—In order to grow the New Zealand Flax successfully in the open air, a sunny but somewhat sheltered situation should be accorded it. This plant revels in heat and moisture during the summer months, but dislikes stagnant water at the root; consequently means must be taken to provide free drainage. In a well-drained garden all that is necessary to do is to provide a free root-run in congenial soil; should, however, the situation be low and damp, with no free exit for superfluous moisture, the soil must be taken out quite 2 ft. in depth, and 6 in. of brick rubble placed at the bottom. On this lay some turves, grass side downwards, and fill up with a good compost, consisting of three parts sound loam and one part leaf-mould and rotten manure. In light sandy porous soils there is no need to provide this drainage; and where the natural staple is a sandy loam, the admixture of a little manure and leaf-mould will be all that is required. When planted in clumps, the Flax produces a fine bold effect, especially when in near association with other forms of plant life. Standing out somewhat prominently before masses of evergreens or shrubs of any description, its characteristic features are more freely displayed. It is, however, a fine subject for isolating on the Grass. In severe weather a few stakes should be placed round it, stuffing in some Fern and covering with a mat.—J. CORNHILL.

2096.—**Geraniums not Flowering.**—Probably the plants are in bad health. How are the roots? Are there worms in the pots? Or have they been kept so close as to produce spindly growth? Some such cause must have been at work. Geraniums now should have plenty of ventilation, be kept near the glass, and be watered regularly as they require it, giving weak manure water two or three times a week—that made from soot is excellent to import a dark healthy green to the foliage and give substance to the flowers.—E. H.

2057.—**Orange Tree not Flowering.**—No dependence can be placed on the fruiting of Orange trees raised from pips; they should be grafted or budded with a standard variety. It sometimes happens that a seedling will fruit at a tolerably early period of its existence, but more often years elapse before flower-buds are formed. If the plant in question is root-bound and healthy, shift it at once into the next size pot; if, on the contrary, it should not appear to need fresh potting, water occasionally with soot water. Admit plenty of light, but screen from the hot sun, and place in the open air about the middle of August for a period of three weeks. If there is any inclination on the part of the tree to form flower, it will do so under this treatment.—C.

2039.—**Dracæna Leaves Withering.**—The only way to preserve the foliage of a plant in a perfect state is to maintain the functions in a healthy active condition. The withering of the leaves is generally caused by a defective root action, brought about by injudicious or neglectful watering. With respect to this latter operation, the golden rule is to allow the soil to quite dry out, and then give sufficient water to thoroughly moisten the soil. If the plant is growing in a room, the leaves should be sponged at least once a week, both the upper and under surfaces. An observance of these instructions will maintain the plant in health and vigour.—C.

2036.—**Bottom-heat for Frames.**—In my article on the above subject in No. 55 some mistakes were made. At line eight read 24 in. for 21 in., and sun-burner seven-eighth inches *wick*, instead of seven-eighth in. thick. "F. H. W." is right in supposing that the top of chimney should be 2 in. from the bottom of boiler. The tin lamp should hold about two quarts, so as to burn for twenty-four hours at least without attention. The conical chimney 7 in. high is glass, and sold at any lamp shop. The outer cylinder is thin sheet iron. My glass frame I find most convenient; for, by having a stand with two shelves, I can remove the seeds when germinated, and the same with struck cuttings, to a lower temperature, which hardens them off before potting.

Its dimensions are as follows :—Height at back 3 ft. ; height at front, 2 ft. 3 in. ; width 2 ft. 3 in. ; length, 3 ft. 3 in. ; top sash on hinges to raise up if more ventilation is required ; front frame, 3 ft. by 2 ft., is made separate, and lifts out for putting in stuff and watering. If "F. H. W." is about to make one, I would advise him to procure the baked clay slabs, as being far better than slate. They can be made to order at any brick-maker's, and if made in three pieces they will not warp in the baking. Care must be taken that the boiler is not without water ; the better plan is to fill it up twice a week.—PETROS.

2059.—**Outdoor Winter-blooming Plants.**—The Christmas Rose, the Winter Aconite, and the Snowdrop are amongst the earliest blooming plants ; there are also Alyssum saxatile, Arabis albida, Aubrietia græca, Daffodils, Crocuses, Daisies, Polyanthuses, and Primroses of many shades of colour, all blooming at an early period of the year. With the exception of the two last-named, all the above-mentioned should be purchased as plants ; they are to be obtained at a reasonable price, and, if nice little healthy plants are obtained, will form good specimens by next season. Pansies should not, however, be forgotten, the seed of which may be sown in July in a shady situation, and the little seedlings, when large enough, should be pricked out in a bed of nicely prepared soil, to be placed in their blooming quarters by the beginning of October. Primrose and Polyanthus seed may be sown now in a pan or pot of sandy soil, keeping it in a frame or shady place until the plants are well up ; then prick them out, as recommended for Pansies, and transplant later on. We would also try a few Violets and Wallflowers (the latter may be sown now), and Pinks. Silene pendula is a pretty and effective spring bloomer, seed of which may be sown in August, and the young plants placed in position when large enough to transplant. If the situation is not too secluded, or exceptionally unfavourable to plant-life, we should suppose that any of the foregoing list would thrive fairly well.—J. C. B.

2027.—**Acacia in Window.**—The lower leaves of Acacia lophantha generally fall as the plant increases in size. We should, however, advise that the roots be examined, in order to ascertain if drainage is defective. Should the young roots at the bottom of the pot appear decayed, take a fresh pot of the same size, well drain it, work away as much of the old soil from the roots as possible without injuring them, which will leave sufficient space for working in some fresh well-sanded mould between the old ball of soil and the pot. This treatment, combined with careful watering, will induce renewed root action, and will have a corresponding effect upon the leaf growth. Water only when dry at the present season, giving enough to thoroughly permeate the soil. In the hot summer weather place the plant in the open air, choosing a sheltered, somewhat shady situation.—J. C. B.

2089.—**Dandelion for Salads.**—The common wild Dandelion is the one referred to ; it may be cultivated and used like Chicory. Sow seeds now in drills 9 in. or 10 in. apart, and thin out the plants to about the same distance in the rows. If seeds cannot be obtained dig up roots anywhere, and plant, leaving the intervals named above between. Keep all flowers pinched off, and blanch the tops by excluding the light, the same as with Endive. Cultivation improves the size of both root and leaves. Some of the large roots dug up from the wayside or meadows, the leaves cut off nearly to the crowns, the roots planted 3 in. or 4 in. apart in boxes, and put in a dark place, would soon yield a serviceable salad to mix with Lettuce, &c.—E. H.

2049.—**Temperature for Ferns and Anthuriums.**—Adiantum Farleyense and Anthurium Scherzerianum require a minimum winter temperature of 50° by night and 55° to 60° by day. By the month of March these temperatures should be increased 10°, otherwise these heat and moisture-loving subjects do not develop freely. They succeed best when so placed that a volume of heat passes around them, such as on a slate bench over hot-water pipes, the surface of the slates being covered with Cocoa-nut fibre, maintained in a moist condition. In this manner a constantly saturated atmosphere is kept up without needing the too frequent use of the syringe. During the summer season, unless it should prove exceptionally cold, but little artificial heat will be necessary.—J. C. B.

2047.—**Specimen Blooming Plants.**—We can think of nothing more suitable for the purpose named than Fuchsias and Geraniums. Free healthy young plants grown along from the present time under favourable conditions would attain fair dimensions and might be had in full bloom by the time specified.—B.

2069.—**Cimicifuga racemosa.**—The Cimicifugas grow freely enough in soil of the ordinary description, preferring a sandy loam into which a portion of vegetable matter enters. A somewhat sheltered and partially shaded situation appears to suit them, one such as may be easily found in the shrubbery or wild garden. In hot dry weather fresh-planted specimens are benefited by copious waterings.—B.

2045.—**Rusty Geranium Leaves.**—The plants in question have probably been watered too frequently. A sour state of the soil will cause rust. Allow each plant to dry well out between each watering. Ventilate freely, but avoid cutting winds.—C.

1952.—**Slugs in Greenhouses.**—I have tried many a way to get rid of slugs, and find the best plan is to lay baits of flour paste, oatmeal porridge, or bran, on pieces of slate or glass. Look over your baits with a light at night, picking up all the slugs you can get, and putting them into a dish among salt and water. Salt may also be sprinkled about with advantage where there is no danger of injury to plants.—M. CUTHBERTSON, *Rothesay*.

2031.—**Eighteen First-class Dahlias.**—Fancy—Gil Blas, Grand Duchess, Flora Wyatt, Lady Spokes, Her Majesty, Henry Walton, Startler, Miss Ruth, Queen Mab. Selfs—Criterion, Rev. Dr. Moffat, Sir G. Smyth, Thomas White, Thomas Goodwin, John Standish, Royal Queen, Miss Henshaw, Mr. Dix.—YORKSHIREMAN IN CUMBERLAND.

2058.—**Making Screens.**—If "A. E." adds a little glycerine to his gum I think his scraps will adhere to the leather.—W. E.

1974.—**Soot-water for Plants.**—To mix soot with water put a handful into an ordinary watering-can ; then add as much water as will wet it, say about ½ in., take the can, and swing it round so as to make the whole go quickly round inside, when it will soon mix. In putting a quantity into a barrel use a stick to stir. The secret is in not putting in too much water.—M. CUTHBERTSON, *Rothesay*.

2053.—**Making a Screen.**—Two ounces of Russian glue dissolved in a quart of water ; let it simmer until reduced to a pint, put on warm with a soft camel-hair brush. Next day varnish with paper varnish.—DIDO.

1973.—**Soot in Gardens.**—If the soot is buried 1 ft. or 18 in. deep, you may plant ordinary flowers or vegetables over it at once, except, perhaps, such crops as Parsnips.—M. CUTHBERTSON.

1959.—**Perennials for Sowing in July.**—The list of hardy perennials of a compact habit that can be raised from seed and will bloom during the latter half of the year is an exceedingly limited one, as by far the larger portion bloom in the spring or early summer. Even the Sweet William, one of the best, flowers in June, and Pansies raised from seed the previous year bloom their best in spring. The Antirrhinum and Pentstemon are both good in their way. Carnations and Picotees sown in July should flower late, as also will the double white Chrysanthemum inodorum, and the various forms of Indian Pink. Myosotis sempiflorus will bloom late in a cool damp place.—D.

1968.—**Crown Imperials from Seed.**—It will probably be three or four years before Crown Imperials from seed will bloom, as all bulbs of this class are slow growers. Keep the seedlings in pots for a year, and then turn them out into the open border, marking the place where planted, and giving the soil a little manure.

2098.—**Plants in Bedrooms.**—Are plants kept in a bedroom window injurious to health?—W. J. [Not unless a very large quantity are kept.]

2099.—**Pigeons' Manure in the Garden.**—Is pigeons' manure good for a flower garden? also will it make good liquid manure for watering Stocks, Asters, &c.?—T. A. H. [You can get nothing better. It is very strong, and you must be careful how you use it.]

2100.—**Grafting Camellias.**—Would a Camellia do well if grafted on an Orange tree or on the Manetti Stock?—J. H. S. [Certainly not ; if you are of an experimental turn of mind you can try it, but you will certainly fail.]

2101.—**Guano Water.**—Will this answer equally as well as liquid manure made from either cow or sheep manure for all general purposes?—J. H. S. [Yes, if it is good and is properly applied. You will find information as to strength in recent numbers of GARDENING.]

2102.—**Cyclamens not Flowering.**—I have six Cyclamens ; they seem very healthy and have plenty of leaves, but no sign of blossom. How can I make them flower? I have given them a little weak liquid manure once or twice. They are old roots, and last year they flowered fairly well.—C. HANKEY. [Probably the plants had no season of rest after flowering last year. You had better withhold water a little by degrees till the leaves begin to flag, then place them in a cold frame or in the open air, giving them a little water very occasionally. They will probably flower well next year if taken indoors in autumn.]

2103.—**Growing Celery.**—I have an Onion bed sown at the end of February last, and which I am afraid will not repay the cost of seed. I should, therefore, very much like to plant it with Celery. It was, previous to sowing, rather heavily manured, and a mixture of soot and salt added. Soil naturally light, with a warm southern aspect. Would you favour me with a few practical suggestions as to the culture of Celery, together with the best variety and time to plant?—NORTHANTS. [Dig out trenches 15 in. to 18 in. wide, and 3 ft. apart from centre to centre, and 6 in. deep. Into the bottom of the trenches dig a good coat of rotten manure. Procure some strong plants of any good dwarf red kind, such as the Dwarf Crimson, Incomparable Red, and plant them at the end of the month 9 in. apart in the trenches, and give them plenty of water. They will want earthing up during summer, an operation which will doubtless be alluded to in GARDENING in the proper season. It is too late to sow now, except for very late crops.]

2104.—**Stopping Vines.**—When am I to stop the shoots of Vines? I have two Black Hamburgh, which have made such rapid progress that their shoots are nearly 4 ft. to 5 ft. long, and the fruit just commencing to come out in bloom, of which there is such a show that the bunches, as nearly as I can reckon, amount to 175 in a house about 30 ft. long and 10 ft. wide.—INEXPERIENCED. [Stop all the shoots upon which bunches have formed. Let each shoot have at least two joints beyond the bunch, and if there is room they may have four or five ; the principle, however, is this :—All the foliage left must be exposed to light and air ; but in your case it would be better to leave the shoots rather long than to take off large pieces now ; you must, of course, remove a large quantity of the bunches if you wish for a good crop. Take off some of the weakest at once, and when the berries are set remove the worst bunches till a reasonable crop only is left. One bunch only must be left on a shoot.]

2105.—**Lilies of the Valley.**—What ought I to do with my Lilies of the Valley in pots after they have done blooming to ensure plenty of blooms next year? I have no greenhouse.—A HARMLESS BULLFINCH. [Pull them to pieces, and plant the crowns singly in rich sandy soil. Take them up, and pot them again in autumn.]

2106.—**Moving Chrysanthemums.**—Can Chrysanthemums be divided and moved with safety now? They have thrown up shoots 2 in. or 3 in. long.—HORTULANUS. [Yes ; move them at once, watering them afterwards.]

2107.—**Frame Cucumbers.**—How many Cucumber plants ought I to put into a frame 6 ft. by 3 ft., heated with stable manure? and which are the best sorts to grow in the above frame?—A. H. J. [Two plants will be plenty. Telegraph is the best kind ; Lord Kenyon's Favourite is also good ; so is Tender and True.]

2108.—**Hot-water Pipes Cracking.**—Will cold water poured into evaporating troughs when the pipes are hot crack them?—D. T. [If the pipes are heated with hot water inside, cold water would not crack them. If the pipes were used as a flue, then the result might be different.]

2109.—**Mulching.**—I often see this word mentioned, but fail to understand its meaning.—DIDO. [By mulching is meant covering the ground with manure or other material for the purpose of preventing evaporation.]

2110.—**Plants for Baskets in Windows.**—What plant or creeper could I buy that would look and grow well suspended inside a window facing south?—W. J. B. [Fuchsias, Begonias, Lobelias, Musk, Campanulas, Saxifraga sarmentosa, Ivy-leaved Geraniums, or any quick-growing plant that will assume a pendulous habit.]

2111.—**Plants for Window Box.**—I have made a frame and covered it with virgin cork to fit the outside of a window facing south ; what plants in pots could I place at the back of it to look well all the summer? I should think if I introduced a pot or two of common Creeping Jenny to grow hanging over the cork it would look pretty.—W. J. B. [Creeping Jenny would do well as an edging, as would Ivy-leaved Geraniums, some of the smaller Tropæolums, Blue Lobelias, and the sweet Alyssum ; for the back you could have zonal Pelargoniums, single Petunias, Fuchsias, Mimuluses, &c. ; indeed there are hundreds of plants suited to the purpose.]

2112.—**Manure for Strawberries.**—Is the application of manure to Strawberry plants in beds that have suffered during the frosts of last winter to be recommended? If so, solid or in liquid, and the kind?—S. N. [Solid manure should have been applied in autumn ; but, if decomposed stable manure can be had, a dressing would do good even now. Do not dig it in ; simply spread it on the surface between the plants ; an occasional drenching of the drainage from a manure heap would be beneficial in dry weather.]

2113.—**Position for Vegetable Marrows.**—Would Vegetable Marrows do well in a position partly shaded by a small Apple tree on one side and Currant bushes on the other? They would receive considerable sun during the day.—W. [Yes, perfectly.]

2114.—**Culture of Balsams.**—In No. 51 of GARDENING ILLUSTRATED good loam, decayed manure, and sharp road grit is recommended to grow these to perfection. Will grit off a limestone road do, or would coarse river sand be better?—PETROS. [River sand would be the best.]

2115.—**Building a Greenhouse.**—How should I construct a greenhouse so that it becomes a tenant's fixture, that could be removed?—J. A. P. [You may construct it in any way you please, so long as you take care not to disturb the ground in any way, nor attach the woodwork to any wall or building. Some old railway sleepers or similar timber will act well as a foundation, if placed on the level ground ; or bricks could be used, provided they were not mortared together.]

2116.—**Forming Rockeries.**—Are there any instructions on this subject in Vol. 1. of GARDENING?—C. B. [You will find information on this subject in the numbers for September 6th, 13th, and 20th ; December 6th and 27th ; January 3rd, and August 9th.]

2117.—**Garlic in Shrubberies.**—How can this be destroyed?—M. L. V. [By perservingly chopping the tops off with a hoe directly they appear, throughout the year.]

2118.—**Raising Melons and Cyclamens.**—What heat is required to raise Melon and Cyclamen persicum seeds?—M. E. L. B. [A moist temperature of from 60° to 70°.]

2119.—**Lifting Dielytra.**—I have a Dielytra spectabilis in the ground showing flower. Would it injure it to take it up and put it into a pot?—J. J. [Not if you well water it first, and lift it with a good ball of earth,

and drop it neatly into a pot of sufficient size. Water it after potting, and place it in a shady place out-of-doors for a few days.]

2120.—**Pricking out Annuals.**—I have some Clarkias, Verbena venosa, Godetia, Linaria, Dianthus, Phlox Drummondi, and Candytuft, sown in shallow boxes in a cold frame; they are now appearing above the ground. Could they be pricked out in the open ground, as I have no other shelter besides the cold frame in which they are at present?—J. J. [When well up, take off the lights by day, and close them at night, till the plants get well hardened; they may then be pricked out in good soil out-of-doors.]

2121.—**Cucumbers Bearing in a Small State.**—I have two or three Cucumber plants which have grown 5 in. or 6 in. high. They are showing fruit at every joint, even the seed leaf joint. Shall I take them out or not? [Certainly; if you wish your plants to last and give you a continuous crop of fruit you must remove all fruit and blossoms as fast as they appear till the plants are established.]

2122.—**Origin of the Polyanthus**—Can any reader inform me of the origin of the Polyanthus? I have seen it stated as likely to have originated in a cross between the Cowslip and Oxlip, and it certainly resembles these plants in the soil it prefers; but I have seen plants uniting it to the common Primrose by many insensible gradations, and have not only found Primroses throw up a stem and produce a truss of flowers, but have seen Polyanthuses lose their tall stem and become to all intent and purposes Primroses, without the loss of their lacing or other characteristics of the individual blossom. [The Polyanthus is considered by botanists to be a variety of the common Primrose (Primula vulgaris): but perhaps some of our readers can say more on the subject.—ED.]

Orach and New Zealand Spinach.—*Hortus.*—These are totally different plants.

Propagating Pyrethrums.—When should the roots of these be divided? [In autumn when they have ceased flowering.]

Gas Boiler.—*A Subscriber.*—Apply to some of the firms that advertise in our columns.

Sportive Leaves on Stocks.—*H. E. S.*—It is not at all uncommon for Ten-week Stocks to produce sportive leaves.

Deutzia gracilis not Flowering.—*T. A. H.*—If the plant is in full leaf it is not likely to flower this year. Keep it growing for the present, and in summer plunge it out-of-doors in a sunny situation, in order to get the wood well ripened. It will then flower next spring.

J. H.—Your communication can only be inserted as an advertisement, in the columns set apart for that purpose.

M. H. H. Terry.—It looks uncommon, but we can form no opinion on such a poor dried-up piece. Send us a good flower packed in damp Moss in a tin box.

Anxious to Know.—We cannot recommend tradesmen. Consult our advertisement columns.

Names of Plants.—*Kitty.*—The leaf is that of an Oleander, or Nerium; for culture see answers to queries. ——*A. B. G.*—Narcissus minor.——*F. W.*—It would be impossible to name a single-flowered Petunia; a packet of seed yields an endless variety; the one sent is well worth growing.——*E. F. Hunt.*—The Toad Flax (Linaria cymbalaria).——*E. L. H. L.*—Allium ursinum, commonly called Ramsons; a good wild garden plant.——*J. B., Cains.*—We cannot name florists' flowers, such as Geraniums, Fuchsias, &c.; this can only be done by a specialist, who has plants near him for comparison.——*H. C.*—A sport of very common occurrence.——*Pink May.*—1, Nicotiana noctiflora; 2, cannot be named without flowers; 3, Spharmannia africana.——*Agnes.*—1, Sisyrinchium of some kind, but cannot tell which from such a scrap of the plant; 2, Santolina incana, or French Lavender; 3, Echeveria of some kind.——*Magna.*—Fern, Asplenium fontanum; flowering plant, Pulmonaria mollis.——*Pansy.*—The climber is Clematis indivisa; the others are the White Rock Cress (Arabis albida) and A. albida variegata.——*A Lover of Flowers.*—Libonia floribunda; it may be propagated from cuttings at any time from now till October.

QUERIES.

2123.—**Salt and Soot as Manure.**—A mixture of soot and salt is recommended as a first-rate manure. Would someone inform me what quantity I might safely give at each dressing to a piece of ground planted with Potatoes? also at what periods of their growth will it be best to apply it? The land is light and poor.—SILLY BILLY.

2124.—**Mushroom-growing in Winter.**—Will some one tell me how to grow Mushrooms in winter? I have a first-rate house heated with hot-water pipes, but I fail to get any Mushrooms. A few come up at first; they are very small, and dwindle and wither.—S. M.

2125.—**Propagating the Eucalyptus.**—Will any one tell me if I can propagate the Eucalyptus globulus from cuttings?—CLAREMONT.

2126.—**Climbers for Filling up Hedges.**—I have a hedge some thirty yards long dividing my flower garden from my neighbour's. The bottom of said hedge was full of dead branches, and there being gaps also, I have put wire netting 1 ft. high all the length, and am anxious to know what kind of dwarf Ivy or other climber would be the most suitable to train on this wire-work, not to grow high, and to fill up well.—T. S. H.

2127.—**Books.**—Can any one tell me of a good reliable work or works on the parrot and its management? also on the culture of the Cactus?—PARROT.

2128.—**Propagating Ivy.**—Will any one tell me of the best way to propagate Ivy?—C. B.

2129.—**Woodlice and Mushrooms.**—I am forcing Mushrooms in two different places, one in a dark place in my greenhouse, and the others in a dark vault. The latter are doing very well, but the woodlice have got at those in the greenhouse and are destroying them all. Can any one suggest any means of destroying them without damaging the Mushrooms?—B. N. C.

2130.—**How to Get Rid of Ants in Frames.**—My Cucumber frames for the past two seasons have been visited by a great many ants. Soon after the plants have been put in they locate themselves among the roots of the plants and stop their growth. Can any one tell me how to get rid of these intruders?—K. N.

2131.—**Plants for Winter Flowering.**—Will any one inform me what plants I can now raise from seed in a greenhouse for winter flowering? or what young plants would it be best to obtain for the purpose?—W. C.

2132.—**Orchard House Peach Trees.**—I have discovered millions of very fat scale on the smaller branches of Peach trees, especially at the end of the house where there is least sunshine. What is the cause? and what is the cure? Our trees have always been quite clean up to this date.—KIRWAN J. FERNIE.

2133.—**Spotted Geranium Leaves.**—I got a cutting of a pink-flowered Geranium in the autumn, and till lately it has done remarkably well. Now the leaves are first covered with small yellow spots, then the whole leaf gets yellow and withers away. Within the last few days I have noticed small marks on the leaves as if a snail had crawled over them; but I looked under the leaves, and could find no trace of any insect. What is wrong?—INGLEFIELD.

2134.—**Weeds in Asparagus Beds.**—I have taken a garden in which there are some Asparagus beds badly infested with Twitch Grass. I cannot get it out without destroying the Asparagus. If I salt the bed to kill Twitch now, will it destroy the beds? Can any one advise me?—H. L. D.

2135.—**Stands for Exhibiting.**—Will any reader inform me how to make a few boxes in which to exhibit Pansies, Asters, and Marigolds, giving the proper size, &c.?—J. B.

2136.—**Points of Good Pansies.**—What are the recognised characters to be aimed at in selecting seedling Pansies to form a fine strain?—J. W. M.

2137.—**Roses on Seedling Briars.**—What is the method to be followed in working Roses on seedling Briars? How should the stocks be treated during growth? and at what age are they fit to operate on?—J. W. M.

2138.—**Palms in Rooms.**—What is the proper treatment for Palms in rooms? I succeed well with a Date Palm, but a Thrinax elegans, bought about six weeks ago, looks miserable; the fans shrivel up and die off.—A. B. C.

2139.—**Pot Roses to Bloom in August.**—I want some Roses to be able to show at a local flower show in August (about the 18th). My Roses in pots are just coming into bloom now under glass. Is it possible to have them in full bloom again for the show? and what treatment should they have to obtain a sound good bloom? They are mostly Hybrid Perpetuals that I have. Good advice would be valued.—OXONIAN.

2140.—**Cold Greenhouse.**—I have a small unheated greenhouse, to which I admit plenty of air during the day, but a sort of green Moss or mould forms over all the pots and nothing thrives. I do not think I overwater. Can any one suggest a remedy? I do hope the subject of cold greenhouses will be thoroughly taken up in GARDENING; many amateurs will be grateful for practical hints.—A. B. C.

2141.—**Crown Imperials.**—Three years ago I planted a few bulbs. They flowered the first year, but ever since they have come up weakly and produced no bloom. The beds are well attended to, and top-dressed with stable manure every year. Why do they not bloom?—F. T. M.

2142.—**Wireworms and Maggots in Gardens.**—I have just taken a garden, which is planted, but is sadly infested with wireworms and a maggot of a dull leaden colour. Can any one recommend a way of getting rid of them?—W.

2143.—**Propagating Biblical Plants.**—Could any reader give me any information appertaining to the cultivation or sowing or striking cuttings, that is, if the seed is attainable or the cuttings procurable, of the following plants, &c., which we find from time to time mentioned in the Bible, viz.—Ling, Aloes, Balm, Cinnamon, Cassia, Bdellium or Musk, Myrrh, Onycha, Galbanum, Calamus (a sweet Grass), Saffron, Spikenard, and Stacte? Can they be grown in this country? If so, how? And what is the proper time for sowing seed or striking cuttings, and where procurable?—J. C.

2144.—**Rock Plants under Trees.**—I have a rockery under the shade of a very thick wide-spreading Beech tree. A few Ferns grow there, but I should be glad to know if any other plants would grow there. The drip from the tree is heavy in wet weather.—A SUBSCRIBER.

2145.—**Yellow Spots on Geranium Leaves.**—I have a Geranium which has made very little growth lately; all the leaves are full of yellow spots, some very irregular and mis-shapen; and although I have bestowed particular care and attention on this plant, yet it does not seem to recover. As it has been so for months I was unable to take cuttings, and should therefore like to save it. Is there a remedy?—H. E. S.

2146.—**Wireworm in Seakale.**—I have possessed Seakale beds for three years, and I find the roots are destroyed by the wireworm. The crops are obtained under Seakale pots by covering them with leaves and hot manure, beginning with about two dozen pots at the end of the bed. As soon as the produce has been cut the pots are renewed row by row beyond the former, and the leaves and hot manure turned over to the new plants, by which a succession is secured. The soil is sandy; and, as many of my neighbours have been treated the same, I should be glad to know of any cure to rid the plants of this mischievous animal.—S. E. D.

2147.—**Cowslips from Seed.**—I have gathered seed of the wild Cowslip two years in succession and carefully sown it, once in autumn and once in spring. In neither case has a single seed germinated. I am particularly anxious to raise it from seed. Can any one give me advice on the subject?—F. T. M.

2148.—**Traveller's Joy** (Clematis vitalba).—Are the flowers of our native species fragrant?—F. T. MOTT.

2149.—**Charcoal Stove.**—Will "M. W. P." say the size of his greenhouse, and if the charcoal stove be bought in Cork can be procured in London? Also the name or maker of same stove?—E. H.

2150.—**Flower-pot Stoves.**—Would "H. M D. B. explain more fully how he constructs his pot-stoves, and what sized pots would be required to heat a frame 7 ft. by 13 ft.?—H. A. T.

2151.—**Jasmines not Flowering.**—I have a Jasmine plant which I brought from France last autumn. It was about to bloom then, and has remained in the same condition ever since. Will someone tell me what I am to do with it?—M. T.

POULTRY.

Disease in Fowls.—I had a large number of fowls last year; they had always been very healthy, when suddenly they began to droop, and I used to find them dead in all directions. I first thought they were poisoned, but such was not the case. Upon examining them I found they were covered with vermin. I had the houses cleaned and (lime-washed mixed with sulphur); but it was all no use; the disease was most contagious, they nearly all perished. I feed them well with meal, oats, and turnips; they have fresh water every day, and a nice grass run. I found one hen dead yesterday, and I am afraid they are going to perish this year also. I had a nice brood of chickens out on January 15; and now, when I thought they were all right, they are all drooping, and four have perished. I should feel very much obliged if I could obtain some information on the subject. Also my fowls lay very small eggs; they are a mixed breed, and were very good ones.—VIOLET.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 4s to 6s; Azalea, 6s to 12s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 6s to 9s; Lily of the Valley, 6s to 18s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus (various), 4s to 9s; Pelargoniums (zonal), 3s to 6s.; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s; Violets (Neapolitan), 4s to 5s; Violets (French), 1s 6d to 4s 0d. —*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Camellias, 1s to 4s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 6s; Roses (forced), 1s 6d to 6s —*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 3s to 6s.

Plants in Pots.—*Per doz.*—Arbor-vitæ (golden), 9s to 18s; Arbor-vitæ (common), 6s to 12s; Arum Lilies, 6s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Aralia Sieboldi, 12s to 30s; Ardisia crenulata, 18s to 30s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Berberis, 4s to 9s; Bouvardias, 12s to 18s; Box, 4s to 9s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Clematis, 9s to 18s; Cyclamen, 6s to 18s; Daphne indica, 12s to 24s; Deutzia gracilis, 9s to 18s; Dielytra, 9s to 12s; Dracæna (green-leaved kinds), 12s to 30s; Dracæna 18s to 60s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Hyacinths, 4s to 9s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Narcissus, 9s to 12s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 12s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s. —*Per pair.*—Azaleas, 10s to 20s; Maiden-hair Ferns (large), 4s to 7s; Aucubas (berried), 4s to 6s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3 each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 36s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 5s to 8s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 20s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 9d.

Vegetables.—*Per* 100.—Asparagus, 1s 6d to 4s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (out-door), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips (outdoor), 3s to 4s; Radishes, 1s 6d to 3s; Herbs, 2d to 6d. *Per doz punnets.*—Cress, Mustard, or small salad, 2s; Seakale, 36s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s.—*Per bundle.*—Celery, 1s to 4s; Horseradish, 3s to 6s; Salsafy, 6d to 9d.—*Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 9d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 4s to 8s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

REGISTERED FOR TRANSMISSION ABROAD.

PANSIES.

FEW plants have been more improved of late years than the Pansies, and, although for a long time little cultivated, they are now becoming universally popular. They can be grown in the shade or the sun, in pots or the open ground, and even in a window box in a London backyard; and the rich and varied colours of the flowers render them the most interesting as well as beautiful of plants. There can be little doubt that numbers have been deterred from growing Pansies of all classes by the elaborate and expensive treatment recommended by some authorities; whereas, it is a fact that many which would have succeeded perfectly in any ordinary garden soil are killed by over-feeding and the introduction of fresh soil containing the eggs of grub and wireworm. Let us suppose that an amateur cul-

GROUP OF BELGIAN OR FANCY PANSIES.

tivator has procured a collection of Pansies of all classes, say in September or October, and that, being afraid to risk them in the open ground all winter, he has prepared a compost of about three parts good rich loam and one part leaf-mould and silver or river sand; let us suppose further that he has got the plants into 4-in. pots, and in a cold frame close to the glass, that he has plunged them, giving them at all times as much light and air as possible—all he will then have to do will be to water them with soft water when required, and guard against too much damp, as damp is a far greater enemy to Pansies than frost. If it be intended to bloom the plants in pots, then they should be repotted in February or March into 8-in. or 10-in. pots, using the same compost as before, but with the addition of one-fourth part of the best old manure obtainable (old well-rotted cow manure being preferable). The compost should be in good working order by being prepared beforehand and protected from too much wet at this season of the year. The pots must be well drained, and after potting they should be again plunged in cold frames or pits, close to the glass, as before, admit at all times plenty of light and air. When the plants have become established in the pots, and the days longer and milder, they should be supplied with plenty of good soft water; and it will be advantageous, in the case of weakly plants especially, to add a little guano to the water occasionally—or, what is better, have a cask with a mixture of liquid manure, consisting of guano and soot, and add a small quantity of this mixture to every pan of water, as it is much safer to give a small quantity often than to give a large dose, say, once or twice a week. As the plants grow it is advisable to furnish them with small stakes, to keep them from being broken by the wind. If blooms be wanted early, say for competition in May or the beginning of June, the lights will require to be taken off the frames only seven or eight hours during the heat of the day; but if they be required for the end of June or July, then the plants should be grown as coolly as possible, with the lights altogether off, except for protection from heavy rains or winds.

For growing Pansies in the open ground any good piece of ground will do free from the shade and the roots of trees; and for early sorts a border facing south or west is best. If the ground be poor, it might with advantage be trenched over and plenty of good old manure and any good free soil forked into it, and thoroughly exposed to the winter's frost and rain; and if the situation be wet it ought to be drained. When it is convenient to prepare the ground the year before it is wanted for Pansies, it should be well trenched, adding plenty of good manure; and a crop of Potatoes, Turnips, or other vegetables, may be taken off it, when it could either be planted in autumn or ridged up all winter, and be ready for planting in spring. Autumn planting ought to be finished by the end of September; during hard frost the beds might with advantage be protected by branches or mats; or, in cases where the collection is not extensive, a pot could be put over each plant. Spring planting ought to be finished by the end of March; the plants require to be inserted up to their shoulders firmly, leaving only the head out of the ground. Plant from 10 in. to 12 in. apart each way, and put small stakes to them at once, to save them from being broken by the wind. Water them with soft water in order to settle them into the ground; give the surface of the bed from time to time a good stirring, and in dry weather a good watering will be beneficial; but were the beds well mulched with old manure or Moss it would serve to keep the plants damp and cool all the summer, and save much watering.

These remarks apply more particularly to what are now known as show Pansies; but the cultivation of fancy or Belgian Pansies may be said to be the same, except that the soil in which they are grown should be a little poorer, and that they should not be planted in the open ground until spring, as they do not seem to be quite so hardy as the show kinds. They ought also to be planted a little wider apart, as they are, as a rule, more vigorous in growth. This class of Pansy is rapidly improving—so rapidly, indeed, that each year's seedlings cast those of previous years into the shade. Bedding Pansies have proved to be most useful, although at first they met with some opposition. The qualities to be looked for in the bedding Pansy are habit and good foliage, and profusion, substance, colour, and size of blooms. The best way to succeed with them is to practise deep cultivation, to give plenty of good old manure, and plant early, so as to get the plants well established before hot weather sets in. These remarks of course apply equally to the culture of the show and fancy Pansies, and we may add that both must have a change of ground every year.

Pansies are propagated by means of seeds, cuttings, and division of the roots. Seed should only be gathered from the best sorts, and care should be taken to see that it is ripe before it is gathered; it may be sown at any time, but it is best to sow in August and September, in pots, and as soon as the young plants will bear handling, to prick them out in pans or boxes, and winter them with the general collection; they will then be ready to plant out the following March and April. Cuttings may also be taken at any season, but July, August, and September are the best months for propagating the general collection. Select for this purpose young shoots from the centre and sides of the plants; good short-jointed pieces, from 2 in. to 3 in. in length, are best, and if a heel or small root can be got with them, so much the better. Where a large stock is wanted, it is a good plan to nip out the centres of the main shoots, when a host of small ones will soon spring up from the centre of the plant; and if a handful of sand be shaken loosely into the middle of the plants, it will encourage small roots to form at the base of every shoot, and thus enable them to be taken off, ready for planting, every two or three weeks. For cuttings, no place is better than the foot of a north wall or hedge, and for late cuttings a cold frame or pit. The soil should consist of a mixture of loam, leaf-mould, and plenty of good sharp river or pit sand. They should be sheltered during severe storms of wind or rain, but when shading is required it ought only to be continued as short a time as possible, as it is apt to make the cuttings "draw" too much, and not root; when rooted, they require to be removed from the cutting bed and planted in the open ground, watered, and shaded for a short time. A damp day or evening is best for this purpose, and by this means a stock of well-rooted, short-jointed plants will be secured for either autumn or spring planting. The old stools may be lifted and divided if required, but propagation by means of cuttings is preferable, as well as more economical, where stock is required.

—— In cultivating Pansies for exhibition, it is requisite in the first place to understand what are the properties of an exhibition Pansy. To gain the best knowledge of this I would recommend going to a good exhibition, where one hour's study with a grower as guide would be better than a volume in print. The next thing is to procure good sorts. Get strong plants, and let them bloom once to show their true colours; then begin to pinch every bloom bud off as it appears, and get some Fern or wooden pegs, and peg every shoot or stem down in the soil midway of the stem. By these means you will get double the quantity of plants you would have by breaking up the roots; do this as soon as you get the plants growing, and, as I said before, pinch every bud off after you know they are right sorts. Then get your cold frames ready; these need be particular in no way if they let in plenty of air and light. Next fill up within 6 in. of the glass with some good fresh loamy soil, the top spit of an old pasture, and some very well-rotted and clean stable manure; if it is not rotted so that it falls to pieces when you handle it it is of no use, as strawy loose stuff will not suit them. Mix it well up, and put it in your frame; level it, and let it settle some weeks before use. The plants ought by August to be well rooted. Take one root up at a time, keeping the label with it, and break every stem off at the bottom; pinch all weak shoots off main stems, and put them on one side with a label to them; then get your best plants or stems you have broken up, and plant in your frame 1 ft. apart each way; when you have finished this, put on your light for a day or two, shaded with a mat, and proceed with the weaker shoots; only you may plant them from 4 in. to 6 in. apart, according to size of plant. When your plants are started in the frame, take off the lights, and never put them on again till frost or snow appears, unless a storm comes on, when you may put them on to stop them from being battered. Always have the lights off when the sun is out, unless it is powerful, in which case raise your lights to give air, and shade the glass with mats. Look sharp after red spider and snails; I lost a very good stock last autumn through red spider. Let the plants keep growing on till spring comes, pinching off every bud as soon as you see it, as by letting them grow you weaken the plants and encourage weak shoots. We will now suppose the show is in May, June, or July; you must see they are kept moist if the weather is dry. Raise the lights 6 in. above the frame to allow a free breeze to circulate through it; and when within about three weeks of the show, let the buds go, and give weak liquid manure, making it stronger as you get near the show; and if you are a beginner, you will find yourself so astonished as you never were in your life at the size of blooms. If you show the plants, you must get as big pots as the show allows, generally about 6-in.; take as many plants up (of one sort) as will fill your pot, and trim the blooms with a camel's-hair pencil, arranging to the best advantage.—LACY GREEN.

—— In exhibiting show and fancy Pansies, they are to be seen to best advantage on neat stands painted green, without paper cards. The largest blooms should be placed in the back row, and the colours should be arranged so as to produce the best effect. Violas are best shown in bunches, and a Dahlia or Rose stand is very suitable for that purpose. As the show day approaches, it will be well to collect the blooms as they expand every morning, and place them in large bowls of clean water, changing it every day; place them in a cool shady house, and they may be preserved fresh from three to six days, according to the state of the weather. When shading the blooms on the plant is resorted to, use a

small covering sufficient to shade the bloom only and not the whole plant. Before arranging the blooms on the exhibition stands, I lay them all out on clean paper for about an hour, by which time they will be a little flagged and more easily handled without the risk of breaking their stalks or splitting the under petals in laying them on the stands.

[The Pansies from which our sketch was prepared were sent to us by Messrs. Carter & Co., who call them the International Pansies, and who have in their nursery a very good selection of fancy, show, and bedding kinds.]

Pinks in Covent Garden.—The common varieties of Pink are largely grown for market, the old white, moss, red, and Anne Boleyn being the best sorts to grow freely and sell well. These are propagated by dividing the old stools at the end of the flowering season. When planted in light soil these slips soon emit roots, when they require no attention except keeping them clean and giving them an occasional dressing of soot to keep off slugs and the common house sparrow, which in sharp weather pecks out the crown of the shoots. When taken up for sale, a little Moss is tied round their roots, and they are sold in dozens, often at fair prices. A popular member of the Pink family is the single variety, or that raised from seed sown in the autumn. Plants raised in this way, by the following spring are so vigorous as to have foliage more like that of a Carnation than a Pink. They are called "Jacks" by the costermongers, who carefully tie them up singly and in pairs in Moss, and label them with some high-sounding name. The disappointment of the purchaser thus imposed upon may therefore easily be imagined when his supposed fine new varieties of double Carnations, Picotees, &c., prove to be when in flower a fine crop of single Pinks. In spite, however, of these tricks of trade, the quantity sold each year shows no diminution.

Spring Flowers in the Market.—Double-flowered hardy Primroses are worthy of every attention, being really beautiful flowers, both as ornamental little garden plants and in a cut state. Forget-me-not, Arabis, Pyrethrum, Phloxes, Violets, Chrysanthemums, Pæonies, Thrift, and similar hardy subjects, are always to be found in the market in spring in large quantities; so also are roots of many kinds of culinary herbs, such as Thyme, Winter Savory, Sage, Tarragon, &c.; small plants of Lavender, Rue, and Rosemary; clumps of common hardy Ferns; indeed, nearly every hardy root that produces either useful leaves or pretty flowers is supplied ready for the purchaser. These are mostly packed in moderate and useful quantities in orange or fish boxes, and are thus in a very convenient form for the buyer to safely and easily take them away.—H. B.

Fuchsia Riccartoni.—There are many places in which this useful plant thrives remarkably well, not only in pleasure grounds and shrubberies, but also by the sides of walks in plantations. A gravelly bottom suits it best, but it ought to have a place specially prepared for it—say a pit dug out 4 ft. wide and 18 in. deep; let the best of the soil be put in the bottom, as this Fuchsia will often root deeply if it finds congenial material in which to develop its roots. If in plantations, it should occupy the most open positions to be found in them, and, as Rhododendrons may be expected to adorn woodland walks during summer, this Fuchsia furnishes a profusion of flowers in the latter part of the year. This variety of Fuchsia is much hardier than many imagine, and where the subsoil is sufficiently gravelly to give free passage to superfluous moisture to pass away, I have seen it grow into a great bush 6 ft. and 8 ft. high, and sometimes a healthy plant will throw up a shoot 6 ft. long in one season. In exposed situations, or where the frost becomes very severe, it would be well to protect plants of this Fuchsia during winter. This may be done with Bracken, and a few sticks driven into the ground to keep it from blowing away. If the tops are killed by the frost in winter, young growths will push up from the root in spring.—G. D.

British Wild Flowers.—The Snake's Head (Fritillaria Meleagris), or common Fritillary, called by the country people "wild Tulip," is a plant which I found in abundance a week ago in a meadow about two miles from Reading. Suitably disposed in our gardens, it would form a graceful addition to their limited number of spring-flowering plants. Even in the wild state there are many varieties—the handsomest perhaps, being the chequered white and reddish purple; there is also a white, or rather greenish white, variety, which is very pretty. The form

The Snake's-head (Fritillaria Meleagris).

of the flowers of all the varieties is very much that of a Chinese lantern. The foliage being scanty and Grass-like, the bulbs, to produce an effect, should be massed in close proximity to handsome foliaged plants. The second wild flower to which I would call attention is that of the Caltha, or Marsh Marigold. The meadows near the river have been golden with the yellow blooms of this plant for the past three weeks. Either in masses or isolated, it is an exceedingly showy flower, and has no real defect to prevent its being an eligible occupant of the spring flower border. Its dark green glossy leaves are very handsome, and the plant grows compact and well furnished with blossom in the full sun. Indeed, so splendid was its appearance in the meadows, that I should only have been too pleased to have been able to transfer, there and then, some of its gorgeous beauty to my flower garden; but I was compelled to be satisfied with a handful of blooms, which I gathered, together with some Fritillarias from a neighbouring field, the two forming on my arrival home a vase bouquet sufficiently handsome for the boudoir of an empress.—T. S. J.

Hardy Crinums.—It is probable that the South African Crinums—at least those which grow in the latitude occupied by the hardy and half-hardy Irises—will also be found more or less hardy under favourable circumstances in England. I have only tested the capabilities of

Cape Crinum (C. capense); flowers white and pink.

two of them, as follows:—C. capense is truly hardy here at Welton (near the centre of our island), where it thrives, flowers, and produces seed in abundance under water round the margin of a pond. This, and a paler variety called C. c. fl.-albo in the catalogues, were formerly to be had at 1s. 6d. a bulb, and might doubtless be had cheaper if a demand arose for them. The pure white variety is more tender, and does not succeed in the pond. The variety called C. riparium is described as being of a richer purple colour, but my specimens raised from seeds do not differ materially from the normal form. C. campanulatum is hardy also, but perishes under water treatment of any kind. We have seen a large plant of C. capense flower profusely for several years at the foot of a plant house in Messrs. Osborn's nursery at Fulham.

Clean Flower Pots.—Amateurs scarcely devote enough attention to this matter, and therefore are troubled with many failures in consequence. Plants are soon affected with disease if grown in dirty pots; the soil soon becomes waterlogged, sour, and mossy, and the minute rootlets refuse to absorb moisture and nutriment from the walls in which they are imprisoned. Two things lead to deterioration in pots—one, and perhaps the chief, the excessive porosity and softness of the material of which they are made; and the other, defective drainage. Pots made of good hard clay, even in size, with sides of moderate thickness, if a trifle dearer, are at least much the cheapest in the end, as these neither get dirty so soon, nor are so brittle, and therefore last much longer. Plants should never be allowed to remain too long in the same pots; frequent shifts both promote health and free root action; and the cleaner and sweeter the pots, the more active will that root action be. Even apart from this, however, dirty pots are unsightly in any plant house; and if it be not desirable at all times to shift a plant into a clean pot, much good may be done by clearing off the Moss on the surface of the soil and re-dressing it with fresh material, and also by giving the outsides of the pots a good scrubbing in water. In large gardens, where many thousands of pots are employed in plant culture during the year, wet days are usually made available for washing them, and it is by no means unpleasant work during the dog days. In winter, however, several hours of pot-washing in very cold water is neither pleasant, nor does it lead to good results. A boiler or copper should be at all times available for pot-washing; and where a large quantity has to be got through, an abundant supply of hot soft water should be at hand. Two tubs should be used—one full of tepid water, in which the pots are placed to soak an hour or two before being washed, and the other full of hot water, in which the actual cleansing is done. If the pots be but moderately dirty, a wisp of bast or hay will make an efficient cleanser; but for very dirty, mossy pots, a brush is the most effective. A semi-scalding in hot, strong soda-water not only assists in the rapid removal of dirt, but destroys parasitical Mosses and causes the pots to dry off at once; they are thus ready for stacking as fast as they are washed. Amateur plant growers should cleanse their pots in the same way, but of course there are fewer to clean; nevertheless, it is well to wash thoroughly, and get each pot as clear from dirt as possible. No person having any regard to the requirements of plant life would ever use pots that have not been properly cleansed.

COTTAGERS' FLOWER SHOWS.

I would advise that cottagers be offered prizes for all the most useful vegetables; and, to save funds, let them go in pairs, taking, say, Peas and Beans together, white and red Cabbage, Carrots and Parsnips, Onions and Leeks, Turnips and Beet, round and kidney Potatoes, and then offer an extra prize for the best collection. In plants, say—one Geranium, one Fuchsia, one Fern, one any other kind in bloom, one any other kind for foliage, would be quite enough. In cut flowers—cut blooms of Dahlias, Asters, Stocks, French and African Marigolds Pansies and Roses should be separate, six of each; then say six annuals; bunches, and best collection of cut blooms, a special prize. Also offer special prizes for horticultural or botanical exhibits of decided merit, such as models, dried specimens or collections; a prize in this section for the best collection of Potatoes, unlimited, takes well. A special prize for the neatest and best-cropped cottage garden, and one for the best bed of Onions are necessary. To make the show really of use in encouraging honest growing and exhibiting, and a better cultivation of the most useful varieties of vegetables, &c., it is really necessary that each entry should be scrutinised by a competent person on the exhibitor's premises a few days before the show. By all means have strangers to judge, if possible. A band of music for dancing greatly increases the enjoyment, and draws gate-money. Entry fees should be as light as possible, say 1s.

Prizes for bouquets of wild flowers might be offered to children. The band should not cost more than £2 10s.; hire of tents and tabling, £6; schedule—say 2s. for firsts and 1s. for second prizes for each exhibit, and 4s. firsts and 2s. seconds for special prizes. £20 should cover all the cost, and the gate-money and entry fees should pay the expenses; but it is advisable to collect subscriptions and have as large a surplus as possible. In the village where the writer resides the first annual show left a surplus of nearly £20, although the schedule and expenses were rather extravagant. Annuals should be about those named above, and should be sown at once. The other plants are all easily procured from either florist, nurseryman, or market gardener. The writer would be glad to give any other information, or to forward schedules of small shows held in his neighbourhood. Schedules or handbills should be out as soon as possible, so as to give an idea of what will be wanted.

YORKSHIREMAN IN CUMBERLAND.

ROSES.

ROSES FOR WINTER FLOWERING.

POT Roses that are managed with a view to produce the earliest flowers in winter under glass, that is, such as are well furnished with unexpanded buds out-of-doors in open quarters before being taken indoors, need little forcing; they simply require the protection of a house or pit, slightly above the temperature of an ordinary greenhouse, to induce them to expand. Where Rose flowers are required all the year round there are none that play a more important part than these, filling up as they do the gap between the latest-opened flowers produced out-of-doors and those that come in under the influence of more heat later in the winter. The ability of the plants under consideration to produce flowers at the time required will, in a great measure, depend upon the way in which they are treated at this time of the year. The flowers which they furnish, as will be evident, are not the production of wood made after they are taken under glass subsequent to being more or less pruned, but simply the result of matured buds already formed, with no pruning at all practised in the autumn, this being deferred until the present time. The plants, when done flowering, are removed to a cold pit or house, where they will merely receive protection. They should now be pruned, the operation being confined to cutting out all weak, worthless wood, and shortening the strong shoots proportionate to the size and strength of the plants, remembering that the larger they get the greater the amount of flowers they will produce, and that a score of good specimens in 11-in. or 12-in. pots will furnish not only a far greater amount of flowers than almost an unlimited number of small plants, but that the proportion of large blooms is much greater than from plants of smaller size.

Potting.—After being pruned, all that require it should be potted at once, giving more root-room where needed. The soil used should be strong loam with a sprinkling of sand and some good rotten manure, but no leaf-mould or light material, such as is sometimes employed, and which is quite unfit for Roses. See that the drainage is sufficient and well secured against the soil getting down into it. In potting these, which will principally be Tea varieties, it is scarcely possible to ram the soil too hard, neither must the pots be filled so full as not to allow sufficient water, of which they will require a daily application through the summer, enough being given to moisten the whole at once. All such plants as do not need larger pots should be turned out; the drainage should be examined, and as much of the old surface soil should be got away as can be done without interfering with the roots, replacing it with new material, which should also be well rammed in, so as to make it quite solid. Previous to potting the plants would be all the better for being laid on their sides and syringed freely with Tobacco water, to which has been added some Gishurst. This not only kills green fly and red spider, but the sulphur which the Gishurst contains is equally destructive to mildew.

Treatment after Potting.—The plants, after being potted, should be placed in a cold pit, deep frame, or under the protection of loose lights in a warm, sheltered position, where they will commence growth, gradually exposing them fully to the air as the roots begin working in the new soil. Later on they should be plunged in a good bed of ashes, sufficiently far apart to prevent any crowding, and to permit of their being attended to with water; the plunging is necessary to prevent their drying up so quickly through the summer, which would occur if the sides of the pots were exposed to the sun and air; there should also be 3 in. or 4 in. of ashes under the pots to prevent the ingress of worms. Coal-ashes are preferable to Cocoa-nut fibre, spent tan, or other material frequently employed, as all these afford a harbour for worms, which the ashes do not. Roses more than many plants appear to suffer from their presence in pots. A few of the strongest branches should be bent down and tied out in a way that will cause them to break from the lower eyes and keep the plants in shape, not with a view to their being formally symmetrical, but so as to induce the production of strong wood from the base, and admit of air and light getting through each plant. As the whole object with this portion of pot Roses is to furnish flowers at the time already stated, all buds that make their appearance through the summer should be picked off as soon as they are formed. The plants must receive regular attention as to the root moisture they require, and should be liberally supplied with manure-water, so as to induce the formation of all the strong wood possible; to still further encourage this, insects and mildew must be assiduously sought for and destroyed.

Standard Gooseberries.—This is an excellent way of training these useful fruits, but one that is seldom seen in practice in English

Standard Gooseberry.

gardens; it is, however, accomplished, and the fruit produced from trees thus trained is in many ways superior to that obtained from trees trained in the ordinary way. It is never advisable to have the heads far from the ground; on the contrary, a clean stem of, say, 2½ ft. to 3 ft. will generally be found a convenient height. In order to have well-shaped standards, it is necessary that training should commence when the plants are small—old, straggling bushes being seldom capable of conversion into anything like satisfactory specimens. Procure young vigorous plants with thick straight stems, the tops of which have never been cut off, and plant them in whatever positions may be desirable, after which apply to each plant a strong stake—if an iron one, so much the better. All side shoots produced within 2 ft. of the ground must be kept pinched off as they appear, and the leader encouraged to grow straight by tying it to the stakes. When the stems have attained a height of 4 ft. and pruning time arrives, it must then be decided upon what height to have the heads from the ground. This done, every bud should be picked out to the required height, when four plump leaf-buds should be left and the remaining portion of the shoot cut off. The shoots produced from the remaining buds the following summer may be allowed to grow at will, and when they have shed their leaves in the autumn they should be gently drawn down into a drooping position, and be all cut to the same length. This bending them down will cause other shoots to be produced from the upper sides of these main branches, and they, in their turn, may be trained slightly down, until a regular and well-shaped head is obtained. In all cases, however, overcrowding of the wood should be avoided—that is, if crops of large and well-ripened fruit be desired. Some growers of standards use galvanised wire frames, made in the shape of an umbrella, on which to train the heads of the trees, but if the branches be kept in their places by means of ties and a few stakes for a year or two, and be judiciously pruned every year, such expensive and formal-looking contrivances may easily be dispensed with. Gooseberries and Currants are grown as standards to a considerable extent in Bohemia and Moravia, the trees being grafted on stocks of Ribes aureum, which has been found to produce vigorous and fertile specimens. —S.

VEGETABLES.

GROWING VEGETABLES FOR PROFIT.

AN industrious man near a town, with a garden large enough to occupy all his spare time may, and, in fact, often does, realise a profit from it beyond supplying his family with fruits and vegetables. Where circumstances permit of this being done, it will be better to deviate somewhat from the ordinary system of cropping, and to cultivate only those plants that experience has shown can be produced in each particular locality in the greatest perfection. Market gardeners often find it answer their purpose better to concentrate their attention upon one or two special articles, and do this well, so as to obtain the command of the market for those particular vegetables or fruits, than to grow an extended selection—acting on the principle that excellence in only a few things is better than mediocrity in a larger number. On warm dry soils early Potatoes are a paying crop, and they may be cleared off in time to plant the land with autumn Broccoli. The Broccoli would in most cases be off the land by Christmas, which would give plenty of time for ridging it up and preparing it for the Potatoes again; I need hardly add that ground cropped like this must be liberally manured, and the crops must be occasionally changed. Short-top and French Breakfast Radishes are a profitable crop when raised early, and would be cleared in sufficient time for Celery, and this arrangement would make a very good rotation alternately with Potatoes and Autumn Broccoli, as the Celery could be cleared off by Christmas. A good bed of Rhubarb, if well treated and sheltered with litter to encourage early growth, would not cost much to make, and would pay well; while there is always a brisk demand for Seakale in the season, which might profitably be taken advantage of by the enterprising cottager who had a turf-pit or frame with the means of raising a little artificial heat. Early Cabbages, to be cleared off by the end of June or earlier, and the land prepared for Turnips immediately thereupon, would be suitable for some soils, and a good patch of Red Cabbages for pickling will usually find a ready sale at a good profit. Onions sown in the autumn tolerably thick, and drawn green when they are a good size towards the end of May, to be followed immediately by Vegetable Marrows, will make a good change with some of the modes of cropping previously named.

There is one point in connection with gardening for profit I think so important that particular stress ought to be laid upon it, viz.—as far as possible to secure the best and truest stocks of each particular plant intended to be grown. Any plant of a good true strain will pay better for the space it occupies, granting the outlay is more in the first instance for the seeds than the inferior quality, even if the latter have equal germinating power; and with this object

in view it may be advisable to devote some attention to the saving of seeds of any really good variety of vegetable, especially as, if this idea be carefully worked out, it may open up another source of profit, cottagers often experiencing a difficulty in securing really good seeds. A careful cottager, who has taken pains in the selection of his plants will soon obtain a reputation among his neighbours for the excellence of his crops, and may by saving seeds occasionally add considerably to his profits. Of course, two of the same family must never be in blossom at the same time, or it will probably result in a crop that will spoil both ; this is the main reason why some kinds of vegetables, especially the Cabbage family, are so difficult to obtain true to their individual kinds. There are too many varieties (so-called) by half, and every year adds to their number, and renders the confusion still greater. Peas, unless very early or very late, are not, as a rule, profitable to grow in a small way ; French Beans may answer for a change of crops, and the same may be said of Lettuces, and the latter may often be used as a catch crop amongst others ; but the main reliance should be placed upon those subjects that are best suited to the soil, and for which the best demand exists in each particular neighbourhood, for the selection of which experience alone will be the surest guide.

There is still another source from which a profit may be realised by those who have some little knowledge of the cultivation of common hardy border flowers, especially those that flower early in spring. There is a large and increasing demand for the decoration of town gardens early in the season by means of Daisies, Wallflowers, Pansies, Pinks, Cloves, Carnations, Sweet Williams, Polyanthuses, common Auriculas, &c. They are all easily increased by division, cuttings, or seeds. They may be grown to a flowering size in one year at a very small cost, and could be lifted with little balls and conveyed anywhere without feeling much check ; and if sold at a rate so as to bring them within the means of the very poor, not only would the transaction be profitable in a pecuniary sense, but it might help to brighten the homes of those who have not too many elevating pleasures. I feel convinced that anything that tends to popularise (if I may use the term) and extend the cultivation of flowers must, in the long run, benefit all concerned in their production. I have ever found that when once a beginning is made and interest aroused, even though in a very slight degree, other and choicer varieties are being frequently added to the stock whenever the means will allow.

H.

Mulching and Watering Peas.—Mulching with various materials is an excellent practice, and one which deserves more attention than it generally receives, as the benefits to be derived from such treatment are very great. The mulching keeps the roots cool and moist, and is especially useful in shallow soils ; in clayey lands, too, which break into large fissures during the drought, mulchings enable rains, when they come, to thoroughly soak the whole of the soil instead of running down the cracks —thus leaving the chief portion of the roots dry, and inducing mildew. The best mulching material depends greatly upon local circumstances : where, for example, sea-weed can be readily obtained it makes a good covering, inasmuch as it retains moisture for a great length of time. Where, however, this cannot be got, half-rotted manure makes perhaps the next. We have likewise frequently seen flags of the Yellow Iris (I. Pseudacorus) cut from the river-side and used for the purpose ; and lawn mowings may also be employed where nothing better can be had, though they are apt to fill the ground with weeds. Before mulching should rain not come, a thorough watering should be given, first prick the surface over with a fork in order to allow the water to penetrate readily—after which put on a good coating of the best material at hand, covering as much of the soil as possible, and if 6 in. or 8 in. thick all the better. If this be done properly, and a good watering given once a week, or as often as seems necessary, the plants will never sustain any sudden check through excessive drought. A good dose of manure-water or guano-water given sometimes will greatly improve the crop. Watering, be it observed, should be done thoroughly ; it is better to water half the crop at a time and do it well than only half do the whole. Pouring water close to the stems of the plants is a practice which is best avoided, as it sometimes causes them to rot. In very dry weather a sprinkle overhead in the evening will be found to be beneficial to the foliage, and also to assist the setting of the blooms.

The Globe Artichoke.—The culture of the Artichoke varies somewhat according to situation and climate. In the north and midlands, it is necessary to cover it in winter with litter or leaves, to protect it from frost ; in the south it is sufficient to earth it up, but even this precaution is not taken everywhere. The plants are increased by seed and offsets. They require an open situation, and well manured deep soil. The Globe Artichoke is considered a very wholesome vegetable, and with good culture it can be obtained in great perfection for at last six months in succession. If cut when about half grown, the Artichoke possesses a very pleasant flavour, and is a very delicate vegetable ; but if the heads be allowed to attain their full growth, or nearly so, they are not so fine in flavour, and have lost most of their tenderness, so that only the base of each scale and the base of the head are fit to eat ; whereas the whole of a young head may be eaten. The Artichoke will grow luxuriantly in rich boggy land in summer, and is not at all a bad-looking plant in large borders and wild gardens, with its noble foliage of a kind of blueish-green, and with its large heads of flowers of a Borage-like blue colour ; but it will not stand our winter in wet quarters. As a kitchen-garden plant, it will grow on any kind of soil, if well manured, trenched, and pulverised ; but no soil suits it better than a good, open, sandy, rich loam, trenched and well manured. The plant is in its best perfection at the second and third year after planting. To plant properly, make choice in spring of good strong suckers, take off the stools carefully with a sharp strong paddle-trowel or Asparagus knife, with some root or heel of the old stool to them, to hold them in the ground ; plant them singly 2 ft. apart, in rows at least 4 ft. apart, or in groups of three in triangles, at 4 ft. apart at least in the row. Protect them as soon as planted, against the sun and cutting winds, with Seakale pots, which are at this season out of use, or with evergreen boughs, or some other convenient protecting material. Those thus early planted will produce fine free crisp heads the same summer and autumn. If the stems also be cut close to the ground as soon as the heads are cut, new suckers will soon appear, and if duly thinned will produce a late crop : thus, by a little trouble and attention, a regular supply of good Artichokes may be had from May to October, which will be much more satisfactory than having a glut at midsummer and none afterwards. The aim should be to get the largest supply at a time when other vegetables are generally scarce. Copious supplies of manure water may be advantageously given to Artichokes during dry weather, especially in the case of old stools that have been in the same soil for a length of time. Previous to watering, the soil between the rows should be slightly pricked over with a fork, to allow of the water soaking in more readily. Whenever watering is attempted let it be done thoroughly, and if a good mulching of half-rotten manure can be afterwards applied between the rows, it will keep the roots in a moist state for a long time, and the effects of the watering will soon be seen.

Globe Artichoke.

AMATEURS' GREENHOUSES.

As an amateur, I wish to give a few hints to others who, like myself, have little time to devote to greenhouse gardening. I am afraid many people, struck with passing enthusiasm by a chance visit to a flower show, or a tour through well-appointed gardens and greenhouses, go home and build a greenhouse, and, after an unsuccessful attempt to grow everything, not excluding Orchids and other stove plants, have given up the whole thing in despair, and abandoned the temple of Flora to the spiders and cockroaches. To these disappointed ones I need scarcely address myself. If they had been true lovers, they would have persevered through all difficulties, and achieved success ultimately. I will assume at the outset the possession of an ordinary greenhouse, a frame, and a reserve bed out-of-doors.

I—**What to Grow.**—This consideration is a most important one. It is necessary to have a stock of plants which will furnish flowers from January to December. Well, in the spring I have bulbs (generally bought for cheapness sake at a bulb auction, and potted in October and November)—Hyacinths, Tulips, and Polyanthus-Narcissi. Then there are Primroses, Deutzias, Lilies of the Valley, Spiræas, Polyanthus, and Dielytra spectabilis, all of which force capitally. These, with an odd Camellia, Azalea, and a few Cinerarias will make a variety and a show through the later winter and early spring months which will gladden the eye at a time when flowers are scarce, and before Nature has put on her vernal mantle of leaf and flower. In summer Geraniums and Fuchsias will be largely represented. Tender annuals sown in spring will be extremely useful—Browallia elata, Rhodanthe Manglesi, and Acrocliniums, being all desirable amateurs' flowers, easy to cultivate, and profuse bloomers. The last two are greenhouse everlastings from Australia, and have a further value for church and home winter decoration. Sowings of these may be made in September for spring flowering. With a few greenhouse climbers, Begonias—which I especially recommend—Musk, and a few miscellaneous plants which obtain a place in my greenhouse, a continuous display of flowers may be looked for through the summer. In the autumn and early winter, Chrysanthemums (cuttings of which have been struck in spring, and the plants grown on in a frame or under a shady wall, and taken inside in September) are the most valuable, and will afford flowers almost

until the earliest bulbs are ready for blooming. Of course, a few Ferns must be grown. When a Vine is trained over the rafters Ferns are especially useful, and with a few plants of the various Lilies (auratum, lancifolium, &c.) will produce a rich effect in the house, and harmonise well with the fruit overhead. The Coleus cannot be kept through the winter in an amateur's greenhouse, but is a desirable addition to the summer stock. The best plan I know is to make friends with a gardener (not a nurseryman) and beg a few cuttings in March or April. They will then strike readily, and amply compensate the little trouble they cost. A few wire baskets filled with Ferns and trailing plants, and suspended from the rafters, do much to redeem an amateur's greenhouse from the air of conventionality and commonplace which often pervades it. A little rockwork—not too much—made of tufa or sandstone and virgin cork (no glaring spar if you value the opinions of your fastidious friends), and planted with Ferns and Lycopods, is also an interesting feature.

II.—**Liquid Manure.**—A liquid manure tank or tub will be necessary, and is best relegated to the most obscure part of the premises. Plants in active growth will do well with a bi-weekly application, and will repay the attention thus given by a wealth of vigorous and healthy foliage and flower. If a manure tank is not practicable, guano or some other condensed form of plant food may be purchased of any seedsmen,

III.—**Soil.**—Some good decomposed turf, loam, silver-sand, and leaf-mould or Cocoa-fibre refuse will fulfil all requirements. Peat is not necessary. A little lump charcoal is a good addition to soils for some plants.

IV.—**Economy.**—A small fortune may soon be expended, and prove no better investment than Turkish bonds. Do not be tempted to buy plants in flower, except they will furnish cuttings, or be of lasting service. Better procure plants to order, and propagate from them, and you will then have the additional pleasure of seeing them grow and bud. A few seeds well chosen will amply repay their outlay.

V.—**Tidiness and Cleanliness.**—Lack of these two virtues—they *are* virtues—will do much to make everything else a failure. The glass must be kept clean; the benches and staging free from dirt (keep a small scrubbing brush at hand, and do not be afraid of elbow-grease); the floor ought to be washed at least once a week, and the pots should not be allowed to become coated with green mould; nor ought dead or withering leaves to be left on the plants. The house, too, should not be permitted to get dingy for want of an occasional coat of paint. Cleanliness is as necessary in the greenhouse as the dwelling-house, and litter and dirt ought not to be tolerated in the former which would not be permitted in the latter. I cannot lay too much stress upon the importance of this subject.

VI.—**Daily Care.**—If success is to be attained, daily, not occasional, attention is absolutely necessary. More harm may be done by the forgetfulness to water on a hot day than can be repaired in a month. "What is worth doing at all is worth doing well."

Read your GARDENING regularly, and not a week or two after date. By regular reading, you will lay in a stock of information which you will find valuable after many days. An acquirement of the rudiments of botany is especially useful, and will add tenfold pleasure and interest to the cultivation of plants. I would urge amateurs not to be careless respecting the correct nomenclature of their plants. There is no need to be afraid of the Latin names; they only require once learning. One who patiently observes the habits of growth of plants must understand them and develop them successfully. Far greater self-denial is exercised by passionate devotees of music and other sciences, but no pursuit yields more lasting pleasure or more intelligent recreation than do the study and cultivation of flowers.

JOHANNES.

Drying Everlasting Flowers.—These need only hang in small bunches with their heads downwards. I do so always, and the stems are perfectly stiff and straight. No need to wire them.—M. G.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 17.—Sowing two rows each of the following sorts of Peas—Giant Emerald Marrow, British Queen, Ne Plus Ultra, and Omega; potting on large Tomatoes for fruiting in pots; planting out another three-light frame with Telegraph Cucumbers, and one with Green-flesh Melons; mulching late Strawberries with chaff cut from stable-litter; clearing off Broccoli stumps, manuring the ground, and getting it dug up for another crop; potting Vesuvius and Dr. Lindley Pelargoniums for autumn blooming; also young Cyclamens, afterwards placing them in heat and shading them during the day; sowing Mignonette in 6-in. pots for house decoration, and another crop of Negro Long-pod Bean; also sowing a little Chervil in boxes and in the open border; planting a border with April-sown Cauliflowers; also Celery and Lettuces, and making another plantation of Cabbages, Savoys, and Brussels Sprouts; placing Tomatoes out-of-doors to harden off ready for planting; topping the shoots of Broad Beans which are in flower.

May 18.—Sowing Canadian Wonder French Beans, and Early Snowball and Strap-leaf Turnips; planting out two rows of Celery; potting on double Petunias and Tricolor Pelargoniums; pricking off Celery and Broccoli plants; planting out Leeks in deep drills; looking over Seakale beds and thinning out the crowns; tying up Brown Cos Lettuce to blanch; hoeing amongst all growing crops; potting-off Chrysanthemum cuttings, Gesneras, Chilies, and Salvia splendens; sowing Scarlet Invincible Sweet Peas for succession, Walcheren Cauliflowers Kight's Tall Marrow, and Champion of England Peas; also Syon House Cucumbers; planting Iresine, Cerastium tomentosum, Vegetable Marrows, and Ridge Cucumbers; putting in cuttings of Pansies; watering trees that have been recently transplanted; syringing Peach trees out-of-doors in order to keep off insects; earthing up Potatoes as fast as they appear above ground; thinning Carrots, Turnips, and Beetroot; hoeing and otherwise cleaning Onion beds; digging land for planting Brussels Sprouts, Cabbages, and Savoys.

May 19.—Potting on Pelargoniums of sorts for autumn and winter blooming; pricking off Stocks, Asters, and double German Wallflowers; looking over the Asparagus beds regularly, and keeping them closely cut down; nailing and tying in the young shoots on Rose walls, and washing them where required with Quassia-chip water to kill green fly; sowing London and Paris White Cos and Neapolitan Cabbage Lettuces, Spinach and Radishes; planting out Tropæolum canariense, Gnaphalium, Centaureas, and Zonal Pelargoniums; preparing pit for planting out Cucumbers; staking Scarlet Runners and Peas as fast as they require support; throwing out more Celery trenches, and making them ready for receiving the plants; hoeing and raking shrubbery borders.

May 20.—Sowing Early Horn Carrots for drawing young; planting out a large space with Early Dwarf Ulm Savoys; also Tomatoes against a south wall; looking over the Peach walls, disbudding the trees where required, picking off curled leaves and keeping them well syringed to keep down insects; potting double Wallflowers and Selaginellas; sowing another batch of Balsams, Iberises, Wallflowers, and Pentstemons; likewise Brompton Stocks, Alyssum, and Oxalis; making a ridge for Vegetable Marrows; putting short Grass between Strawbery plants on which the fruit has set; preparing land for sowing annuals; tying creepers in conservatory.

May 21.—Sowing also Mustard and Cress; planting out Calceolarias, Pelargoniums, and other bedding plants; also Autumn Giant and Self-protecting Cauliflower plants in deep drills; giving the Vineries where the Grapes are swelling a good soaking of guano water; thinning out Beet, Onions, Carrots, and Parsnips, and running the Dutch hoe between the drills; thinning out Spinach and Turnips; shifting Celosias into 10-in. pots, and placing them in a warm pit; potting Mimulas for the conservatory; also Ice-plants and Fuchsias; sowing Rudbeckias, Polyanthuses and Myosotis; also French and Long-pod Beans, Champion of England Peas, and another crop of summer Spinach; planting a small bed of White Celery to come into use for kitchen purposes early, and pricking out young Celery plants in open border; removing Tomatoes to cold pit; disbudding Peach trees out-of-doors, and thinning the fruit, so as to leave three to a shoot; also thinning Apricots for the first time, and nailing in all leading shoots; examining Rose trees for maggot.

May 22.—Planting out Gourds, Marrows, and ridge Cucumbers; looking over Cucumbers and Melons, earthing and stopping them, and fertilising them where required; sticking Peas and earthing them up; mowing and rolling down Grass; potting Humeas into large pots, and placing them out-of-doors; also Calceolarias and Primulas; shifting young Vines into 10-in. pots, and placing them in a Vinery; sowing Giant Emperor Stocks out-of-doors, and Intermediate Stocks in boxes placed in a warm frame; also sowing French Beans in pots for planting out and placing them in heat; planting a few Chilies out-of-doors in the warmest situation available for them; transplanting Beetroot where seedlings have failed; watering seed beds with guano water; also all kitchen garden crops that are likely to suffer from drought; likewise young Cherry trees, and afterwards mulching the roots with half-rotted manure; tying in leading shoots of espalier fruit trees; earthing-up Cucumbers that are growing freely.

Glasshouses.

Potting Newly-struck Plants.—Cuttings of the more generally-grown climbing and bushy-habited stove plants recommended to be put in about the end of March will now be well rooted and have got sufficiently inured to the full air of the house to admit of their being potted. As to soil, those plants that will grow in loam, especially in stoves where a strong heat is maintained, will generally flower freer in it that in peat; consequently it is better in such cases to use loam; but its employment is not to be recommended for plants that have their growth unduly restricted.

Bouvardias.—Cuttings put in in March will by this time have made considerable progress, and should now be ready for transferring singly to 3-in. pots. The points of the growths should be nipped out in order to induce them to break freely. They will succeed in either peat or loam, but where the latter is to be had of good quality, and to it is added some well-rotted leaf-mould, sand, and fully decomposed manure, a mixture will be formed that will push them on in the way desired. They should be kept in a warm, genial, temperature, with a moderately moist atmosphere, plenty of light, air in the middle of the day, and a thin shade from bright sunshine until they have got fully established. B. Vreelandi, one of the dwarfest and most compact of Bouvardias and a very free-flowerer; B. jasminoides, white and free in regard to growth; B. Humboldti corymbiflora, white, with very large flowers and bunches; B. Hogarth, scarlet; and B. elegans, also scarlet, finer and larger than Hogarth, will all be found sterling kinds. Plants that were cut back some time ago, and which have now broken freely, if not already partially shaken out and repotted, will be in a condition to be treated in that way, using compost like that recommended for the younger stock, but in the case of these there is no need to push their growth on so fast as the young plants, for, having all the season before them, they have time sufficient to attain a size large enough to be convenient.

Flower Garden.

Auriculas.—Owing to our keeping the frames a little closer than we have been doing, and removing some of the pots into a warmer house, we have been a little earlier than we otherwise would have been in getting the blooms open; and the continued cold weather has retarded the later sorts so much that we have a good bloom yet. Out-of-doors the finer varieties of the alpine section are now at their very best; the colours are more brilliant than those under glass, and varieties that have shaded edges under glass are not shaded in the open air; this is not invariably the case, but it is so with some sorts. These hardy Auriculas are not much injured by the weather, and have certainly an exceedingly fine effect amongst Primroses, Anemones, Muscari, spring-flowering Saxifrages, and other plants that are in blossom early in May. Most of the growers are now busy re-potting, and directions have been given in previous numbers as to the method of procedure. After re-potting the frame should be kept close for a few days, and the plants must be shaded from bright sunshine; the offsets must be kept quite close, especially such as have no roots. I generally place them under a hand-light, and then place small bell-glasses over them to keep out the air.

Carnations and Picotees.—We have not yet placed pots of these intended for exhibition out-of doors. The weather has hitherto been so cold as to quite stop the growth of the plants. Keep the pots free from weeds and the plants from insect pests. If it be intended to flower any of them about three weeks earlier than usual, it will be necessary to place the pots at once in a rather warm house. Blooms of the perpetual-flowering section ought now to be plentiful, and they should be freely produced until after midsummer, for, as the leading flowers die off, the lateral growths push up and continue to produce flowers, though of smaller size—hence the name perpetual-flowering. Young plants must not now be neglected. A cold frame or a cool airy house is the best place for them until the weather becomes warmer.

Dahlias.—Plants of these ought now to be quite ready for planting out, but as yet it would not be safe to do so. The plants should be in pots sufficiently large to prevent their becoming root-bound, and so far apart from each other that they will not become drawn. Admit air freely, removing the lights altogether when the weather permits. See that none of the plants suffer from want of water, and apply it in the morning in preference to the evening while the temperature is so low. The border for the plants may again be forked over.

Forcing Pinks.—These belong to quite a distinct type from the laced section with white

grounds. Anne Boleyn is a good and useful sort, and of newer varieties we have Derby Day, Lord Lyons, and Lady Blanche, the latter a pure white variety with smooth flowers; it is by far the best of the white sorts. Now is a good time to put in pipings of them. They strike freely in a hotbed on a very gentle bottom heat. The frame should be kept rather close until the cuttings are rooted, when air should be given more freely without moving the pots from the positions which they occupy for a week. When fairly established plant them out in the open border until the last week in September, when they should be taken up and potted in good soil, and the pots should be placed in a cold frame until they are wanted to be placed in the forcing house.

Polyanthuses.—These seem to delight in cold weather; their blooms in the open border appear to be quite uninjured, the colours coming out in their richest hues; our only trouble is the sparrows, which will not let the blooms alone. The plants in pots seemed as if they would exhaust themselves with the production of flowers, and as there is abundance outside, we picked the flowers off the pot plants, and planted the whole of them out in rich soil; there they will be no source of trouble until it is time to pot them again in autumn.

Aquilegias.—We grow nearly 100 of these in pots, and, so far, they have caused but little inconvenience, except watering them when necessary. Now they force themselves upon one's attention, as the flower spikes are rising strongly. No one who has only seen the finer species and varieties of these in the open border can form any idea of their delicate beauty when grown in pots. A. cœrulea is particularly beautiful, and the golden-yellow flowers of A. chrysantha have an excellent effect either singly or in masses. Give them plenty of air, water freely at the roots, and syringe to keep the leaves clear of red spider.

Lawns and Shrubberies.

Shrubberies, Plantations, and Borders.—On dry warm days the hoe must be used where weeds make their appearance. In herbaceous borders plants requiring supports should have them; mulching with well-rotted manure will materially assist weakly-growing kinds, and aid in fully developing the flowers. Annuals should be kept free from weeds, and thinned out where necessary. Many kinds which have been grown in frames, such as Stocks, Asters, Zinnias, &c., may now be planted out, choosing showery weather for the operation; the same observations apply to perennials from the nursery beds. Seeds of nearly all kinds of annuals, biennials, and perrenials may now be sown.

Lawns and Grass Plots.—Grass should be rolled about three days before it is mown, and again directly afterwards; edges of beds and verges should be neatly clipped with shears or cut with the edging iron. Any subsidence in newly made plots should be at once remedied. In every case where it is necessary to lift and relay turf, immediately it is down it should be thickly covered with fine rich soil; the unsightliness of this for a few days will be amply rewarded by the Grass being saved from burning, and by its becoming green in a much shorter time than when it is left bare, as is too often the case; moreover, it fills up any interstices which may be left, and acts as a fertiliser. It is also advisable to sow about two bushels of seeds of fine lawn Grasses per acre at the same time, lightly raking over the surface; it may then be left for a few days, raked over again, and thoroughly rolled; thus treated, a good lawn may be formed even in dry weather. In all small open spaces surrounded by buildings, where radiation is excessive, water should be laid on, so as to be available when required, for the purpose of keeping the Grass in good condition. A very frequent source of failure in the case of lawn Grasses is defective drainage.

Climbers on Walls and Fences.—These should be pruned, cleaned, nailed, and mulched. With very little care or trouble, walls and fences in towns might be made extremely pleasing to the eye during summer. Few really good evergreens are available for the purpose; one, however, which is not sufficiently used is the Euonymus; this is a most excellent subject for covering walls; it grows freely and withstands smoke. Some of the shrubby Honeysuckles may also be made available for the same purpose, especially on open fences, and when mixed with Ribes the effect is strikingly pretty. Climbing Convolvuluses and Nasturtiums will also assist in beautifying unsightly structures, whilst in out-of-the-way corners Scarlet Runner Beans may be used with advantage.

Fruit.

Vines.—If in successful Vine culture one matter demands a larger share of attention than another, it is the constant battle which we have to wage with insect pests; and amongst these red spider and thrips are the most formidable. These latter, if taken in time, can be effectually exterminated by fumigation; but the former does not yield so readily when once it has gained a footing, and this shows how important it is to adopt preventive measures. These consist in keeping the roots well supplied with moisture and nourishment, the atmosphere charged with ammonia, at all events during the earlier stages of growth, and judicious and regular ventilation. A check through inattention to any of these matters is not unfrequently instrumental in producing bad results. If red spider has already appeared, first look to the conditions here indicated, and then sponge the affected foliage with soapy water. The remedy of applying sulphur to the pipes is as useless as it is dangerous in the hands of the inexperienced. Late Vines will now or shortly be in flower, and to make assurance doubly sure, frequently tap the rods with the hand, in order to disperse the pollen. Muscat Hamburgh, Mrs. Pince, Muscat of Alexandria, and Lady Downes, if gone over separately with a camel's-hair pencil charged with pollen from other varieties will not only set more freely, but will swell more evenly. Take off all superfluous bunches before they are in flower; what are left will set more freely, and the laterals should also be stopped at the same time, as growth should continue unrestricted at the time of flowering. If the borders be in any way dry, water liberally with warm water. One is constantly being asked, How often and when do you water your inside borders? but it is not possible to satisfactorily answer such questions; all that can be said is that they may be watered freely, provided the drainage be good, and at any time rather than they should suffer in the least from drought. Of course, the most unobservant would know better than to produce excessive atmospheric moisture by watering at the time when the Vines are in flower, and when they require a somewhat dry air in which to set their fruit freely. Grapes colouring should have free ventilation during all weathers, and if dull fires must be kept up, high night temperatures should be avoided. If there be any danger of the border getting dry, do not scruple to water, even though the Grapes are ripe; such watering will not harm them if abundance of air be afterwards given to carry off excessive moisture. Outside borders that have been artificially protected should now have the covering material removed, the soil pointed over, and to prevent cracking, a coating 2 in. thick of horse droppings should be applied. Where shutters or other water-tight coverings have been used watering may be requisite; therefore the borders should be examined, for, though the present crop may have finished perfectly, it should be remembered that next season's fruit is, so to speak, manufactured this season; and if there be any lack of water now the consequences will be apparent enough next season, inasmuch as tendril-like "shows" will be produced in lieu of well-developed ones. As soon as recently-planted Vines have taken a firm hold of the soil, free growth should be encouraged by closing the ventilators early on sunny days and running up the temperature to 90°. Syringe both Vines, walls, and floors at the time of closing, and conserve the moisture in the border by keeping it well mulched with stable litter.

Kitchen Garden.

Easterly winds, cold though they be, have some redeeming qualities, and one of them is drying the soil, which has allowed surface-stirring amongst seedling crops, and also bringing up arrears as regards Potato planting and seed sowing, such as Carrot, Beet, Broccoli, and winter greens generally, all of which, if not yet sown, should have early attention, as should also the sowing of French Beans and Scarlet Runners; the latter should be sown in shallow trenches, to admit of liberal waterings in the event of drought setting in. The earliest sown Spinach ought now to be fit to gather; therefore the remains of the winter Spinach may be dug or trenched in, when the ground will be suitable for Beet, Peas, Broccoli, or Cauliflower. In order that no unnecessary exhaustion of the soil may take place, the old stems of Brussels Sprouts, Kales, or Broccoli should be cleared off as soon as the produce is used; and as soon as practicable let the ground be lined out into Celery trenches, or be dug or trenched, according as it is required for the forthcoming crop. There should be no fallows, accidental or otherwise, in kitchen gardens; on the contrary, each successive crop should, as it were, prepare the way for the one that is to follow it; and in furtherance of this, notes as to dates and positions respecting the various crops will require to be kept. The labour of keeping such a diary soon becomes a pleasant duty, but those who do not care to take this trouble—so-called—but who crop on the haphazard principle, would at all events find it advantageous to adopt the simple rule of never allowing two crops of a like nature to succeed each other on the same plot of ground, but should endeavour to have the character of each successive crop as remote as possible.

GLASSHOUSES & FRAMES.

CARNATIONS FOR WINTER BLOOMING.

Few plants flower with so much certainty as the Carnation; but, for early forcing, the flower buds should be formed, or nearly so, before the end of October. I have lifted plants from the border about that date with a profusion of buds upon them, which continued to open during a greater part of the winter. Of winter, or tree Carnations, as they are called, there is now a great variety, but the white, such as Avalanche, the pink Souvenir de la Malmaison, and the scarlet and rose-coloured varieties are most useful. I would advise no one to have more than three or four distinct kinds, and these only such as are known to be profuse bloomers. Whether old plants that have flowered during the last winter and spring or young plants have to be dealt with, no time should now be lost in transferring them from their winter pots to the open border, where they must remain until they have completed their growth. Provide a bed in a sunny, open, but sheltered situation, and put the plants out about 2 ft. apart. Reduce the old balls considerably, taking away the crocks and spent soil, without shaking the roots out altogether, and plant them well up to the collar. If the bed consists of ordinary garden soil, then fill round each ball with light rich soil, consisting of leaf-mould, loam, and sand, in equal parts, for a space of 6 in. all round. This will be sufficient for the roots during the summer, and will give a good ball of soil with them at lifting-time. Plants that have not been cut down yet will be pushing about the base of the flowering shoots; therefore do not remove the young shoots now, but cut back to them, and when the planting is finished stake each plant and tie them, but not too tightly. Let all the shoots grow; the larger the bush the more flowers, only give them room as the plants grow. If all has gone on well each plant will be profusely furnished with plump buds by the end of October, when preparations must be made for lifting them. For bushy plants, such as I am contemplating, and such as fine young plants will make if planted out in time, 9-in. pots, at least, will be required; and, rather than reduce the balls too much, I would give them a larger size. Get the plants up, at all events, with good balls, by first cutting round them with a spade, and then getting it under them and lifting them clean out of the ground. Transfer them at once to the pots by lifting the ball carefully with both hands and dropping it gently in and fill round with light soil, giving the pot a slight shake to settle it; but do not make it too firm, for that would only injure the roots; watering thoroughly will settle all effectually. This is a better plan than growing the plants in pots all the summer, for they grow better and want less attention, and experience no check at all by lifting if it be done with ordinary care. The

plants may be transferred at once to the conservatory or house in which they are to flower; for, like the Camellia, they want exceedingly little forcing. A warm light greenhouse or frame is the best place for them, and they must have all the light possible, ventilation, and little or no moisture overhead; a damp low temperature causes the buds to rot without opening. J. S.

Everlasting Flowers for Greenhouse.—Among hard-wooded plants now in flower in nurseries few are more beautiful than Aphelexis macrantha and its varieties. In the shape of small bushy plants, Aphelexis may be used in a variety of ways, and their lively purple blossoms last, either on the plants or in a cut state, for months. These Everlastings are seldom grown by amateurs, on account of some imaginary difficulty attending their cultivation. They are, however, no more difficult to grow than many less beautiful plants. Cuttings, consisting of the flowerless shoots, should now be taken off and inserted in well-drained pots filled with equal parts of silver-sand and sifted peat. Use a sharp knife for removing the cuttings, and avoid bruising them as much as possible. Make the soil round them firm when inserted, and place the pot containing them in a larger one, filling in the vacancy between the two with sand or fine soil. Plunge the whole in a gentle bottom heat in a close frame or Cucumber house. Careful watering is necessary. When well rooted pot the young plants in well-drained 4-in. pots, using peat, broken potsherds or broken bricks, and a little charcoal. When again established, remove them into a cooler temperature, and when their pots are filled with roots, shift them into 6-in. pots, using the same soil as before. Abundance of air and water are necessary at all times. Large plants are not so useful as small ones, because they want training, which gives them a formal appearance; and by striking a potful of cuttings yearly, good, bushy plants, full of bloom for several months in the spring, may be obtainable. A. macrantha purpurea grows more upright than the type, and its flowers are superior to it in point of colour. A.m. rosea is also well worth culture. —C. S.

Plumbago capensis.—This very distinct old-fashioned plant should be grown in considerable numbers by those who have to keep up a succession of flowers. For late blooming, and to succeed the plants that have come in with ordinary greenhouse treatment, a portion may now have their shoots stopped, and in the course of another week or ten days be plunged out-of-doors in an open situation, where all that they will require is their shoots being trained, so as to prevent their getting into a straggled condition, and sufficiently supplied with water. In cases where the plants are furnished with roots enough to fully permeate the soil within the pots, manure water may be given once a week; this will have the effect of inducing a stronger condition of growth, which will have a natural tendency to further retard the formation of flowers, an object which it is desirable to attain in order to induce as late a disposition as possible to bloom through the autumn and winter.

Vallota purpurea.—This free-growing and brilliant-flowered bulbous plant is one of the best of autumn decorative subjects which we possess. It is often grown with a little extra warmth in spring in the way in which the Amaryllises are treated. Where some are wanted to come in earlier than usual, such treatment has the effect of inducing them to do so; but where they are wanted to come into flower late, they should be treated on the cool system, as in an ordinary airy greenhouse, but fully exposed to all the sunlight available; so managed, when the plants are strong they will produce a succession of flowers till the autumn is far advanced.

The White Trumpet-flower (Brugmansia Knighti).—This fine old plant is seldom met with in an amateur's garden, notwithstanding its beauty and simplicity of culture, especially when planted in the bed or border of a greenhouse. It only requires to be annually cut into the old wood, and kept clean, to furnish a charming succession of pure white blooms among its abundant pale green foliage. Wherever there is a bed in the middle of a small conservatory or greenhouse, instead of a stage, it is an admirable plant to place in the centre of it, its beautiful head of trumpet bloom and soft rich leaves forming such a fine object around which to arrange the other flowers. It is very extensively grown in tubs, which are stored in cellars or places safe from the frost during winter, and brought out in summer and placed on walks near the houses. Here, in the sun, pruned and leafless specimens soon break into bud, flower finely in the autumn, and form very striking objects.

Knight's White Trumpet-flower (Brugmansia Knighti).

House and Window Gardening.

ARRANGEMENT OF WINDOW PLANTS.

A FEW days since I remarked a window garden so pleasingly and effectively arranged, as to present a marked contrast to all others in the vicinity. The plants were of the ordinary description, but they were evidently chosen as being best suited for the place. Not only did they exhibit signs of painstaking culture, but the arrangement showed an intelligent appreciation of the good effects to be produced by judiciously intermingling such plants as vary considerably, both in form and colour. The form of arrangement will naturally depend upon the shape and aspect of the window. Those windows which project slightly from the dwelling best admit of tasteful grouping being carried out in them; but in almost every dwelling space enough will be found to allow of taste and judgment being exercised. Although no arbitrary rules can be laid down for plant arrangement, yet some general instructions may be given which may prove of service to the inexperienced. In the first place, no window can be considered well furnished unless it contains graceful drooping plants suspended in a basket. Some of the plants best fitted for window culture lend themselves well to this treatment. Some, such as the Wandering Jew Saxifrage, are of extremely easy culture; and a well-grown specimen, with its pendulous offsets drooping down and intermingling with the other inmates of the window, certainly presents a very attractive appearance. The common Musk, again, displays itself to greater advantage when grown in this manner. Then we have such plants as Russelia juncea, Dracæna vivipara, Panicum variegatum, and many beautiful kinds of Ferns, which thrive admirably in such situations, and with good attention will last in beauty for an indefinite period. Tropæolums, Maurandias, Lophospermum variegatum, Cobæa variegata, and Ivies, may also be cited as especially suitable for the purpose. My intention is, however, rather to indicate the description of plants needed than to give a list of kinds; as the grower will, in the course of his experience, meet with a number of graceful-habited subjects well adapted for this mode of culture. In this matter the grower will also need to select his subjects according to the aspect of the window; a Fern, for instance, will thrive admirably in a north aspect, where a Tropæolum would give but little satisfaction, and *vice versâ*. The central object in the arrangement should be a foliaged plant of some kind distinguished for its graceful habit and for its verdure. Where there is space nothing is more suitable than a Palm, the more hardy of which may be kept for several years in health in a small pot without materially increasin size. If there is not space enough for Palms, then some of the many forms of Dracænas may be selected, or a Grevillea, or Acacia, or any kind of slender-stemmed upright-growing foliaged plant. This, together with one or more kinds of Ferns, and a pot or so of the fresh green Selaginella, will give plenty of verdure; and if the flowering plants be judiciously selected with respect to height, habit, and colour, and the whole arranged with an eye to general effect, the result will be very pleasing. Where there is space, more than one basket may be suspended. In the window already alluded to there were three—a Tradescantia zebrina in the centre, flanked by a fine Musk specimen and Panicum variegatum. The three essential points to be arrived at are a judicious blending of colour and verdure, and a tasteful disposition of the various subjects employed. I have been induced to offer these few observations, as I have noticed a general tendency to crowd together a number of flowering plants, thereby creating a blaze of colour. This is all very well as far as it goes, but it does not realise the ideal of window gardening, which, in addition to skilful culture and variety of subject, should certainly include good taste in the general arrangement.

J. C.

Flower Vases.—The floral vases for the room table have been nearly universally neglected, although it is here, perhaps, that we find most scope for the really artistic—that is to say, the beautiful—arrangement of flowers, more especially hardy ones. Although both hardy natives and tender exotics may often be combined in room vases with the best results, there is a great difference between the tastefully-filled vase found on the table in most old country houses and modern dinner-table vases; it is not, however, too late to mend, and what we now plead for is a more natural style of grouping in the last-named class of decoration. Our modern floral decorations, of which that now engraved is an example, however neat or graceful in form, never give us glimpses of floral luxuriance and tints of pure colour as do the old-fashioned masses of Lilies, Irises, Narcissi, and Tulips arranged with their own, and consequently most appropriate, leafage. Modern floral arrangements for the dinner-table will certainly fall into disuse, owing to their formality and want of true artistic beauty. Not so vases skilfully filled with hardy flowers; such vases every true flower painter is pleased to imi-

tate, and every lover of flowers to enjoy and admire.

ANSWERS TO QUERIES.

1975.—**Parsley for Exhibition.**—To grow good specimens for exhibition, prepare your ground by digging in and mixing well a liberal quantity of old horse manure and a little leaf-mould, if procurable. If you wish to have one or two good specimens, pot off just now eighteen plants into small pots, and grow them on in your cold frame till about the third week in May, then plant out about 16 in. apart each way. If your strain can be depended on, twelve of the best will be plenty to plant out. After they are started to grow vigorously, give liquid manure twice a week. Let them be the last thing you lift for the show, and be careful to leave a ball of soil about them that will fill a 7-in. pot; water after potting. If you wish to grow them on in pots, use one-half rotten turf, one-fourth rotten manure, and one-fourth leaf-mould, with a sprinkling of sand; but they are likely to do best planted out. I have grown the plants of the Fern-leaved Parsley 18 in. across.—M. Cuthbertson.

1914.—**Improving Soil for Potatoes.**—One of the most important elements in the successful culture of Potatoes is found in trenching or deep tillage. Soil that naturally produces but a poor crop may be greatly improved if trenched and well limed. A sprinkling of salt is also useful, and there are generally good results following from a dressing of phosphates or of artificial manures that largely contain them. Soils that do not favour the Potato have also been greatly improved as far as the production of that valuable tuber is concerned by the growing of a green crop and turning it in—such, for instance, as a crop of Rye sown in September and dug in at the end of the following March. As a rule, sand will grow good Potatoes, and, with fair dressing of any kind of animal manure, should produce a good crop.—A.

1929.—**Lilium auratum Out-of-doors.**—Where the climate is so cold that such hardy bulbs as Liliums are killed in the winter, the obvious course would be either to give the bulbs in the ground ample protection, or to lift and pot them after the stems have ripened, planting out again the following summer. A bucketful of ashes laid over the soil and bulbs should give ample protection, and a Seakale pot or large flower-pot turned over the ashes should keep them dry, and the bulbs beneath safe from danger. If the climate also prevents early blooming, the best remedy is to grow on the bulbs in pots until the stems are well thrown up, and then turn them out. If this were done the Lilies should bloom in mid-season instead of in the autumn.—D.

2092.—**Cultivating Blackberries.**—Blackberries planted in good land in rows 5 ft. or 6 ft. apart, trained to a wire trellis 6 ft. or 8 ft. high would undoubtedly yield good results. The growth should be kept moderately thin to obtain fine fruit, and the roots be mulched over with manure. The pruning, of course, should be done in autumn or winter. All suckers from the base not required to lay in should be pulled off as soon as they appear.—E. H.

2031.—**Show and Fancy Dahlias.**—Out of so many fine exhibition Dahlias it is very difficult to select the best eighteen kinds, but the following gives a first-class selection, and one that cannot fail to please any grower:—Show kinds—Alexander Cramond, shaded maroon; Charles Backhouse, fine scarlet; Her Majesty, white edged purple; John Wyatt, crimson-scarlet; Ovid, fine purple; Mrs. Stancombe, canary-yellow, tipped with fawn; John Neville Keynes, grand yellow; Herbert Turner, fine French white; and Henry Bond, bright rosy-lilac. Of fancy kinds—Fanny Stuart, red, tipped white; Eccentric, yellow ground, tipped with bright scarlet; Sam Bartlett, blush, striped crimson; Mrs. Saunders, yellow, tipped white; John Lamont, maroon, striped black; Tippy Bob, canary-yellow, striped rose and purple; James Carter, buff, striped crimson; Hercules, yellow ground, speckled crimson; and Regularity, blush white, striped crimson.—A. D.

2037.—**Window Boxes.**—There are a variety of ways in which these ornaments may be made both cheap and effective. An oblong box constructed of ordinary 2½-in. deal, made a trifle wider than the window-sill the narrowest way, and Hazel sticks in their natural state split in two and pointed one end, then bradded to the box and varnished, will have a very pretty aspect; the knottier the Hazel sticks the better, and these should be 1 in. higher than the box ledge. Virgin cork can also be used, which is exceedingly pretty. Miniature palings, with a gate in centre made of wood and painted green with a white background, is very appropriate, and will attract the attention of many a passer-by. Simple wooden boxes, with designs of an ecclesiastical character painted upon them, are not at all out of place. At least a dozen good-sized holes should be made in the bottom for drainage; a moderate quantity of potsherds strewn about, or a few cinders or light ashes, will do no harm. I should rather recommend "Window Gardening" to mix his mould with stable manure, without straw, rather than Cocoa-nut fibre, and water slightly but regularly, and frequently if exposed to much sun. I have found that seeds, especially those of hardy plants, grow well in such soil. If the creepers have already been in pots and done well, I advise him to bury pots and all in the box mould, as removal might prove fatal.—Newt.

Vase of flowers and grasses in early summer.

2089.—**Dandelion for Salads.**—Dandelion makes an excellent winter salad, and may be collected in the fields; but if sown in April in rows plants of a better quality will be obtained, especially if care be taken to select the seed from the broadest-leaved varieties. To blanch Dandelion, prick out strong plants in a row, and in October earth up with from 4 in. to 8 in. of light soil. As soon as the plants begin to appear above ground cut off the shoots at the collar of the root. Thus treated, Dandelion resembles the Barbe du Capucine (the blanched shoots of the Chicory).—Ombu.

2075.—**Mustard and Cress on Flannel.**—Cover a champagne or other bottle neatly with coarse new flannel; soak the seeds for a day or so; then they become glutinous, and will adhere to the flannel more readily. Thoroughly soak the flannel-covered bottle in water, and gently press the seeds on it, covering the bottle all over; keep it in a warm light place, turning it once or twice a day that the seeds may grow evenly. Great care must be taken in watering (which should be often) not to wash off the seeds; either sprinkle gently, or keep the bottle full of water and let it trickle over the sides. When ready for table put a flower in the mouth of the bottle; it will look very pretty.—A Subscriber.

2146.—**Wireworm in Seakale.**—Fork up the land between the Seakale rows or clumps. Pick out all the wireworms seen. Insert Potatoes or Carrots in different places among the Seakale roots, leaving a peg to mark the site of each. Examine them twice a day, pull out, and destroy the worms, and return the roots to the holes again, repeating the operation daily till the worms are all destroyed. This is the best and the cheapest way of eradicating wireworms from a small plot of land.—E.

2123.—**Salt and Soot as Manure.**—When the Potatoes are fairly through the soil is the best time to apply salt and soot; and 10 lb. of the former and a bushel of the latter per square rod will be a safe and beneficial dressing. Scatter it evenly between the rows and lightly fork it in. If the land is very poor, and there is a prospect of a dry hot summer, dress with the same quantity of each again just previous to earthing-up finally next month.—H.

2132.—**Orchard House Peach Trees.**—The scale insects have been introduced unobserved on some unclean plant. They are easily got rid of in winter by painting the trees over when the leaves are off with Gishurst Compound—6 oz. to 8 oz. dissolved in 1 gallon of soft water, thickened to the consistency of paint by adding sulphur, lime, soot, and clay in something like equal parts, and applying it with a soft brush, taking care the buds are not loosened by being rubbed the reverse way. The Gishurst solution without the other materials may be used now on all the thicker branches, or wherever there is room to use a small brush dipped in the compound frequently to dislodge the insects. A weaker (4 oz. to the gallon) solution may be syringed over the trees, well wetting

those parts where the brush has not touched. The garden engine should be used often, and with some force, as insects dislike cleanliness.—E. H.

2124.—**Mushroom Growing in Winter.**—I have known failures to occur in Mushroom houses from the hot-water pipes being placed so close to the beds as to injure Mushrooms when they came up with too much dry heat. Perhaps this may have something to do with the failure in this case. If the house is evenly and moderately heated, and the proper materials available for making the beds, there should be no difficulty in having plenty of Mushrooms. The best time to begin for a winter supply is early in September. The best manure is that obtained from hard-fed horses; that from Grass-fed animals, or, indeed, any kind of soft food, such as roots, &c., is comparatively useless. I have no doubt many failures may be traced to this cause, or to the manure being obtained from horses that are taking medicine, as I know manure from such a source does fail to produce Mushrooms. Having obtained the right kind of manure, shake from it the longest of the litter, and throw the short manure into a heap to ferment, to drive off some of the moisture and the rankness as well. In the meantime examine the house: clear out all corners where woodlice may congregate, and whitewash the walls. Mushrooms may be grown in a dirty place; but cleanliness is a safeguard against insects. When the manure has become hot, turn it over, mixing all together, and leave it to get hot again, when it may be shaken up and made into a bed, treading or beating it down as firmly as possible. When finished, the bed should not be less than 1 ft. in depth; place a trial stick about the centre as a guide, and when the heat in the bed falls to 90°, and is steadily declining, spawn the bed at once, just burying the spawn beneath the surface, using pieces about as large as a hen's egg, and placing them 9 in. apart. Make all firm again, and cover the bed 1 in. in thickness with good sandy loam. In three or four days, if the temperature of the bed keeps steady, beat it down firmly with the back of the spade. If the materials are collected for the first bed early in September, it may be made up and spawned by the end of the month, or a little earlier; and it should produce Mushrooms by the middle of November. If a large supply is required, make a new bed once a month, to come on in succession.—E. H.

2093.—**Propagation of Clematis.**—The hybrid forms of Clematis Jackmanni are propagated by grafting on roots of the common kinds early in spring before growth begins. Pieces of root will do, and one good bud will be sufficient to each graft. Pot as soon as grafted, burying the union, and plunge in a gentle hotbed. Keep close and shaded till the buds burst, then gradually inure to air.—E. H.

2063.—**Humea elegans Dying.**—We can only surmise that the plants in question received an overdose of water, thereby causing a stagnation of the functions. The Humea is one of those plants which when shifted into a large pot grow with great rapidity, but at the same time unless very carefully treated with respect to watering it is liable to go off in the manner described.—J. C. B.

2094.—**Propagating Cistus.**—They are generally propagated by layers; or the young shoots will strike under a hand-glass in a shady border in summer. The best plan to adopt in this case would be to peg the bare shoots down, leaving the green points erect, and cover the pegged-down parts with a couple of inches of peat and loam. They will emit roots, and perhaps new growths will spring up also.—E. H.

2090.—**Ferns in Vineries.**—All the greenhouse Ferns will succeed in the temperature named. The following are vigorous-growing kinds: Pteris serrulata, P. longifolia, P. cretica albo lineata, P. tremula, Aspidium exaltatum, Adiantum cuneatum, A. pedatum, A. concinnum, A. tenerum, Asplenium bulbiferum, A. flaccidum, Cyrtomium falcatum, Doodia lunulata, Neottopteris nidus avis, and Woodwardia radicans.—E. H.

2091.—**Climbers for House Roof.**—I suppose there is some soil for the plant to grow in, either in a box or some other receptacle. There is plenty of choice among the Ivies and Virginian Creepers, any of which would soon cover a roof, or the two might be blended together. Plant a Gloire de Dijon Rose and Clematis Jackmanni on the trellis, and let them intertwine.—E. H.

2095.—**Slugs in Frames.**—Pieces of Orange-peel, laid hollow part downwards, are good baits. Cabbage leaves smeared over with grease attract them also, but they must be examined late in the evening and early in the morning and the slugs killed.—E. H.

2089.—**Dandelion for Salads.**—The smooth-leaved Dandelion makes an excellent salad when the young leaves are chopped up and eaten with salt and vinegar. It will grow in any out-of-the-way place by putting in small pieces of root, and will quickly increase.—G. R.

1924.—**Ferns for Damp Cave.**—Trichomanes radicans would undoubtedly thrive in such a position. Any of the following we should suppose would also succeed very well:—Asplenium Trichomanes and its varieties; A. adiantum-nigrum and A. fontanum, and the two Mosses Selaginellas Kraussiana and helvetica.—J. C.

1924.—**Tortoise in Vineries.**—Tortoises are usually fond of milk and will drink it freely; they also like garden green stuff as food; Lettuce especially they are fond of. It is usually believed that they are partial to beetles and cockroaches, but this is incorrect. They will not do harm in a Vinery, but if the floor is of soil may some day suddenly disappear, having buried themselves for a long rest.

1931.—**Varieties of Chrysanthemums.**—Twelve good incurved Chrysanthemums are as under—Bronze Jardin des Plantes; yellow do.; Prince Alfred, Venus, Princess of Wales, Mrs. G. Rundle, General Slade, Sir Stafford Carey, Queen of England, Lord Derby, Princess Beatrice, and Rifleman. Of button-hole kinds—Bob, Mdle. Marthe, Rose Trevenna, Cedo Nulli, Little Gem, Cedronella, Canary Bird, and Fabiola.—A. D.

1974.—**Making Soot-water.**—There are two methods of overcoming the buoyancy of soot in water. If a clear liquid is required, enclose the soot with a stone or other weight in an old bag. If not, mix the soot with a little wet manure or soil before putting into the water, it will then mix easily with water.—GEORGE DUFFIELD, *Winchmore Hill, N.*

—— I find that a very good plan for preparing soot-water for plants is to put a quantity of soot in a bag, tie it up, place the bag in a large pan or tub, and fill with water; the soot soon becomes saturated, the strength going to the water; and the result is good, clear soot-water.—J. E. A.

1967.—**Book on Horticultural Chemistry.**—I would recommend "Reason Why" to get "Johnson's Science and Practice of Gardening." It can be procured at 171, Fleet Street.—T. J.

1979.—**Calochortus flavus.**—The seed may be sown now in well-drained pans of loam and leaf-mould, and placed in a cold frame in a shady situation. The Calochortus requires a light sandy loam, in combination with a warm situation and perfect drainage, thriving best, in a general way, on rockwork. In low damp places the sorts should, in any case, come somewhat above the ground level.—C. B.

1976.—**Climbing Roses not Flowering.**—Without knowing the treatment to which the Roses have been subjected, it is really a difficult matter to assign a cause for the failure. Ventilate freely during the season, and if they make no satisfactory growth take them up early in the autumn and examine the roots, which are probably in a bad state. If this should be the case, the better plan would be to remake the soil and plant young plants.—C. B.

1978.—**Iris chinensis.**—We should think that the Irises, having now become once well-established, would be likely to bloom. At any rate, no good result would be likely to be effected by removing them. We would give them the full advantage of the sun during the growing season. A good hot summer would probably cause them to form flower.—C.

1933.—**Creepers for North and East Aspects.**—For a north aspect nothing can be better than Ivy, although Kerria japonica, Jasminum nudiflorum, and Forsythia suspensa will thrive in such a situation. On the north-east may be planted evergreen and Ayrshire Roses, golden variegated Honeysuckle, and Pyrus japonica.

1952.—**Slugs in Greenhouses.**—I would advise the following plan to get rid of the slugs in a greenhouse, viz.—to go every night with a lamp the last thing, and look well over the plants, when will be found the slugs on the leaves or on the sides of the pots. By doing so the house may soon be rid of that troublesome pest.—J. E. A.

—— Place every evening Cabbage or Lettuce leaves amongst the pots; also laying here and there one on the plants themselves, as it is probable that some of the enemy take refuge during the daytime under the foliage. About ten in the evening examine the leaves; and in the course of a few days the greater portion of the vermin will have been captured, and perseverance for a longer period will exterminate them.—J. C.

—— My plan is to search diligently at night for them, as they come out at night to do the mischief. My herbaceous Calceolarias were attacked by them, and that is the way I got rid of these pests.—T. J.

1953.—**Azaleas Growing too Soon.**—Some growers make a point of taking out the young shoots made before the buds expand. There is, however, no necessity for so doing, as their development does not materially interfere with the expansion of the bloom. If these young growths are removed others will form, but they are oftentimes not so strong, and the wood does not mature so early in the season.—J. C.

1982.—**Treatment of Cactus.**—The roots of the plant in question are probably in a bad state; hence the unsatisfactory state of the foliage. Turn the plant out of the pot, choose another of the same size, well drain it, and then with a sharp-pointed stick remove as much of the old soil from the ball as possible, so as to admit of some fine well-sanded mould being worked down between it and the side of the pot. Water only when dry, and place in a light airy situation.—J. C.

2130.—**How to get rid of Ants in Frames.**—Scatter guano thinly in their runs, as both this and sulphur they dislike; and I have often made them shift their quarters by using these judiciously. When they can be got at away from the roots of plants, boiling water will settle them. Laying pieces of sponge about the frame smeared with treacle will attract them; and when any number has been got together, the sponges may be cast into boiling water. Perseverance usually conquers.—E. H.

2142.—**Wireworms and Maggots in Gardens.**—Turn as much of the land over with the fork as possible, and pick out the wireworms and maggots; the latter are probably the larvæ of the cockchafer. Place pieces of Carrot or Potatoes just beneath the surface of the ground to trap the wireworms, examining them frequently and killing the worms. With perseverance, a small garden may be cleared by these means without the crops suffering much injury in a short time.—H.

2129.—**Woodlice and Mushrooms.**—Very probably the atmosphere in the greenhouse is too dry. Woodlice are generally more troublesome in a dry arid place. Pour boiling water round the sides of the beds, or wherever they hide up; place a toad or two in the recess where the Mushroom bed is; and place a few 6-in flower pots about the beds, partly filled with hay or Moss. When not feeding, the insects will retire beneath the hay in the pots, where they can easily be destroyed.—E.

2128.—**Propagating Ivy.**—Ivy cuttings may be planted any time from October to March, with a certainty of their growing. Cut off points of shoots about 1 ft. long; trim off the lower leaves, and plant firmly in the ground in rows. The choicer variegated sorts may be planted under hand-lights.—H.

2126.—**Climbers for Filling up Hedges.**—Any of the Ivies will do. Even the strong-growing Irish variety may be kept down to the height named by annual cutting in spring, and weeding out the long shoots as they are formed with the knife during summer. One of the smaller-growing variegated forms, such as Marginata argentea, will look pretty; and, not being so rampant, will not entail so much work. The common Periwinkle, Vinca major, will be suitable, and will make a neat base to the hedge with a little trouble in trimming and training.—E. H.

2134.—**Weeds in Asparagus Beds.**—Salting Asparagus beds now to kill Twitch will kill the Asparagus roots. The only way to get rid of it is to get round and under it carefully with a small fork; and, as Twitch is mostly a surface-rooting plant, this can be done, I should think, without injuring the Asparagus roots, which, in the case of old beds, are generally deepish down. If the Twitch cannot be got at in this way, make a new plantation of Asparagus on clean, well-worked land at once, and dispense with the old bed as soon as possible.—E.

2152.—**Cow Manure.**—Is this useful for ordinary garden purposes?—E. S. [You can have nothing better. It is best mixed with a little soot, and allowed to become decomposed before being used.]

2153.—**How to Grow Coleuses.**—What treatment do Coleuses require?—PROPAGO. [Light sandy soil, plenty of heat, sun, air, and water.]

2154.—**Quassia Water and Soft Soap for Rose Wash.**—I shall be glad to know the strength of the Quassia water when applied alone, and what quantities of Quassia water and soft soap should be used for the combined wash.—H. BRADFIELD. [4 oz. of Quassia to 1 gallon of soft water. For the combined wash add 4 oz. of soft soap.]

2155.—**Balsams for Exhibition.**—When is the best time to sow Balsams to be ready to exhibit in the last week in September? and would they do in a cold frame better than in a Vinery where there is a quantity of other things kept?—H. LEWIN. [Sow at once. The frame would be better than the Vinery.]

2156.—**Azalea Cuttings.**—In the autumn I struck some Azaleas; they grew for some time, but are turning yellow and forcing themselves out of the soil, which is peat with a little sand on the top; they are well watered and kept in a cold house. Can you tell me why they do not thrive?—S. J. C. [Probably they want potting off singly. They are potbound.]

2157.—**Muscat Grapes Spotting.**—I have got the spot on my Muscats. It comes on them just as they are finishing their first swelling and then stoning. It is a very small brown speck, hardly visible to the eye; after a while it dimples in and then goes off quite bad. Would any one tell me the cause of it, and how to prevent it spreading?—C. W. [We have had much experience of the disease you complain of, but we can suggest no real remedy. Perhaps some of our readers may be able to assist you.]

2158.—**Planting Vines.**—Is it now too late to plant a Vine? If not, what kind should I purchase? I purpose planting it outside a lean-to unheated glass structure (south aspect), and drawing it through a hole under the sill to train up inside the roof. Any hints as to the best way of planting will be most acceptable to A NOVICE. [We should advise you to wait till autumn, and before that time we shall most likely publish articles respecting the planting of Vines.]

2159.—**Pruning Passion-flower.**—I have a Passion flower in my conservatory which has grown very wild and straggling; is it too late to prune it?—NANCY. [Thin it out at once, leaving of course any shoots which show flower.]

2160.—**Soils for Geraniums and Fuchsias.**—What is the best compost for these?—NANCY. [Loam and rotten manure or leaf-soil in equal parts, and some road sand.]

2161.—**Well-rotted Manure.**—How long ought manure to lie before it is well rotted?—NANCY. [Till it can be crumbled in the hand. Constant turning will facilitate decay.]

2162.—**Primula Seed.**—I have a pink and a white Primula, which have just finished flowering. Can any one tell me whether by keeping them I am likely to be able to ripen seed for sowing next year? I have no greenhouse or hotbed, but an unheated conservatory.—NANCY. [If you place them on a sunny shelf in the conservatory you may be able to save a few seeds, but they are hardly worth your trouble.]

2163.—**Cucumbers Dying Off.**—My Cucumber plants grew well and looked very healthy until they began to fruit, when the plants suddenly died off; what is the cause?—PRACTICAL GARDENER. [It is probably the Cucumber disease which has been such a trouble to many growers of late years, and for which we have never yet heard of a practical remedy.]

2164.—**Propagating Auriculas.**—When is the best time to increase alpine Auriculas by division?—W. D. [After they have done blooming—say the end of June.]

Cucumber Frame against Walls.—*E. R. A.*—We do not think the lights could well be made to slide sideways; the best course would be to hinge them at the back. They could then be lifted upright and fastened back to the wall if necessary.

Index for Gardening.—*Chas. E., Chester.*—The Frontispiece and Index to Vol. I may be had through all booksellers, or from our office, price 3d. complete.

House Slops for Hollies and Currant Trees.—*Subscriber.*—They must be placed in a tub for a few weeks, and exposed to the air, and be well diluted. Great care will be necessary in their use.

Egg Plants.—*H. T.*—These require a warm frame to grow them well; any rich soil will suit them. They want plenty of water overhead and at the root when growing. They may either be planted out or grown in pots.

Raspberries.—*Swansea.*—To produce fine fruit the canes must not be too close together, and the suckers produced at the bottom must be kept cut off, with the exception of enough to supply canes for next year.

Red Sage.—*Subscriber.*—Any nurseryman should be able to supply you.

Hyacinths from Seed.—*J. M. C.*—Your efforts in this direction will, we fear, end in disappointment. Our nurserymen always buy their Hyacinths from Holland, which they would not be likely to do if they could raise them at home.

C. B. F.—The disease is called "curl." It is caused by the sudden alternations of heat and cold. The only remedy is that of protecting the trees from cold winds in early spring.

Shading for Greenhouse.—*P. B.*—Try "Summer Cloud," to be obtained in tins at any good seed shop.

C. W.—The leaves appear to be scalded.

Liquorice.—*W. T.*—You will find all the information you ask for, and more, on this subject in Shaw's book on "London Market Gardens," price 3s. 6d., at our office, or from any bookseller.

One in a Proper Fix.—The insects sent were common earth worms.

Speckled Geranium Leaves.—*Mrs. W.*—This is often caused by bad drainage and over-watering. Let the plants get dust-dry before you water them again.

Scale, Thrips, &c.—*Mrs. W.*—We cannot tell you the origin of these insects. They are visible to the naked eye.

Names of Plants.—*Aberdeenshire.*—Ranunculus amplexicaulis.——*F. H. W.*—We cannot name plants from leaves only.——*W. Watson.*—The Rose sent was Catherine Mermet, as far as we could judge from its withered condition.——*T. Layley.*—1—Male plant of Aucuba japonica; 2—Daphne Mezereum probably, but we cannot tell without flowers; 3—Euonymus japonicus aureus variegatus.——*Amateur.*—1, Senecio Ghiesbreghti; 2, Alchemilla alpina; 3, Arabis albida; 4, Pulmonaria angustifolia; 5, Chrysanthemum frutescens; 6, Chrysanthemum frutescens var. Linnæanum; 7, Cyanotis repens.——*H. C.*—It is impossible to name a plant from such a specimen as that sent.

QUERIES.

Before sending queries it is well to consult the first volume of GARDENING, *which contains an immense number of practical articles and questions answered by men well acquainted with the subject.*

2165.—**Saving Wallflower Seeds.**—How can I save Wallflower seeds that will produce double flowers? I have both double and single varieties.—S. U.

2166.—**Management of Fern Cases.**—I have a Fern case about 17 ft. by 9 ft., at present containing Maiden-hair and other varieties. Can any one furnish a few hints as to management?—F. J. D.

2167.—**Grafting Plums on Apricot Stocks.**—I have an Apricot which year after year partially dies off, and is unproductive. If I cut away the Apricot branches will the stock do for grafting Plums or Pears on? and if so, what sorts?—J. H. R.

2168.—**Coprolyte.**—To what use can I put this in the culture of plants?—A. H. J.

2169.—**Paste for Destroying Rats.**—Would "Rustic" kindly say where this is to be procured?—A SUBSCRIBER.

2170.—**Pansy and Aster Seeds.**—Would any readers tell me what their experience of seeds has been this spring? I have a cold frame facing south, and have carefully followed the instructions contained in GARDENING, but without success. Two or three seeds did come up, but almost immediately turned yellow, and died off. I put them in three weeks ago.—E. M. H.

2171.—**Blight on Apple Trees.**—How can I clear my Apple trees of what appears to be mildew? On examining each of the little patches, I find very minute insects with red blood.—EAST SHEEN.

2172.—**Watering Early Potatoes.**—I have a row of early Potatoes up under south wall nearly 1 ft. high, the foliage of which is beginning to curl somewhat. Would it be advisable to water them? they being, of course, under cover by night, and consequently unable to receive any moisture in the form of rain or dew.—NORTHANTS.

2173.—**Road Sweepings as Manure.**—Having to obtain manure for my garden by gathering horse droppings from the roads, I should be obliged if some one would tell me what is the relative strength of such material, and how to apply it to various crops. Is it good for Celery?—G.

2174.—**Nitrate of Soda for Plants.**—Would any one inform me how to apply this as a manure, and what effect it has upon plants and flowers?—BYKER.

2175.—**Flowers and Gas.**—Will any reader kindly tell me what plants will thrive in rooms where gas is always used for some hours daily, as I find great difficulty in keeping any alive?—A LOVER OF FLOWERS.

2176.—**Soot-water in Vinery.**—I have been sprinkling the walls and floor of my Vinery every day at shutting-up time with soot-water, and the Vines look very strong and healthy. If I continue the soot-water now the fruit is set, will it cause rust on the Grapes, or injure them in any way?—NOVICE.

2177.—**Pennyroyal.**—How can I preserve the roots of this in winter?—JESSE.

2178.—**Growing Cucumbers.**—I think of trying my hand at Cucumber growing under glass as soon as the bedding stock is moved out. Will some one give me a few hints as to training, &c.? What kind of wire is used? With what and how is it fastened—up the rafters or horizontally? How many wires would one plant require? Should they hang loosely in loops or not; and with what are the plants fastened to the wires? Size of greenhouse 20 ft. by 10 ft.; flue, two sides, and front.—JOHN BENNETT.

2179.—**Leaf Impressions.**—Will Mr. Hodson, of Liverpool, kindly tell me how the oiled sheets are to be prepared? and also how the carbonic paper is to be prepared, or where it is to be obtained?—C. A. R.

2180.—**Sowing Begonias.**—How should Begonia seed be sown? I have failed to raise plants from seed several times.—L. W.

2181.—**Ants and Fruit Trees.**—For the last six years (though not before) I have been suffering from a plague of black ants, which infest the Cherry and Apricot trees, coating the under part of the leaves with black eggs, which not only destroy the fruit, but also the trees. Have any readers experienced this nuisance? and can they suggest a remedy?—C. J. B.

2182.—**Destroying Gnats.**—What is the best means of getting rid of these objectionable insects? A swarm of them seem to have generated in a wine cellar, from whence they escape over the house and into the conservatory. Flowers of sulphur have been burnt with but slight success.—NOTNUM.

2183.—**Gloire de Dijon Rose Failing.**—I have one of these Roses in my greenhouse. It is 3 ft. high, and has lately been very severely attacked with mildew. I applied flowers of sulphur to it, as well as mildew composition. All the old leaves fell off, and now the new ones all curl up whenever they come out of the bud. What is this curling of the leaves, and what should I do with the plant?—ROSÆ AMATOR.

2184.—**Striking Cuttings of India-rubber Plants.**—Can any one give me information as to striking cuttings of an India-rubber tree? Should they be struck in water or soil, and is heat necessary?—EMILY HAY.

2185.—**Rose Maggots.**—I have a great number of standard Rose trees, and have but very seldom been able to free them from a small green maggot which destroys the buds. I have tried several remedies for some years without success. Can any reader suggest a remedy?—W. ROWCLIFFE.

2186.—**Propagating Frame.**—Can any one inform me the best mode of making a propagating frame in a greenhouse. I have a space about 2 ft. 6 in. wide by 8 ft. long I could use for it. The propagating frames as advertised are too much like toys.—PROPAGO.

2187.—**Growing the Bush Marrow.**—I have had a plant of this given to me; will some reader tell me if it requires any support when the fruit shows? To an ign ramus like myself it seems impossible for the stem to support the weight of the fruit without artificial props. Any information on the cu ture of Bush Marrows will be thankfully welcomed by EAST SHEEN.

2188.—**Wireworm in Gardens.**—My garden was three years ago pasture land; it was well dug and trenched. Now the wireworm is destructive to all vegetables and many flowers. Can any of your correspondents say what can be done to get rid of this pest?—B. P.

2189.—**Manuring Parsnips, &c.**—Can any kind of top-dressing be applied to Parsnips and Carrots. I took my garden too late to give them manure at the time of sowing. Would liquid manure benefit them and Turnips?—G. R.

2190.—**Flowering Shrubs for Borders.**—I want two flowering shrubs to plant in small beds on each side of my front door. What are the best kinds?—THOMAS MIXTURE.

2191.—**Plants in Rooms.**—I want to keep a stand of Ferns and flowers in a sitting-room window. Ought I to remove them from the room when the gas is lighted? I have a verandah outside my house; I have thought of having sides of glass built up so as to make a kind of little conservatory, but the roof would be of wood; how would that answer?—G. H. M.

2192.—**Disease in Gooseberry Trees.**—My Gooseberry trees this year are attacked by a disease that we do not understand. It appears on both leaves and fruit. It first appears in the form of a bright red blotch on the leaves, which extends and swells to a considerable size; also on a great number of the berries. Can any one tell what is the cause and what the cure? Some of my neighbours complain of the same.—JNO. HOPKINSON.

2193.—**Trailing Azaleas.**—Can any one tell me what a trailing Azalea is like? and if it is possible to get one? It is a Scotch badge, so it must be hardy to a certain extent.—ENFIELD.

2194.—**The Best Pansies.**—Will any reader please to tell me which are the best six Pansies in cultivation?—X. Y. Z.

2195.—**The Best Roses.**—Will any reader tell me which are the best six Roses in cultivation?—X. Y. Z.

2196.—**Leaf Impressions.**—Mr. Hodson says (p. 96), "Take your leaf out, and place it between your carbonic paper," &c. Will he kindly tell me in an early number what this carbonic paper is—where it can be obtained, or how to make it? Would the black paper sometimes used for producing duplicate writing answer the purpose? I fancy that would scarcely blacken the leaf sufficiently.—S. D. BIRD.

2197.—**Stove for Greenhouse.**—I have just bought a portable greenhouse, 15 ft. long by 7½ ft. wide. Can any of your readers recommend a stove or lamp capable of keeping out the frost?—N. S.

2198.—**The Feather Grass** (Stipa pennata).—How can I raise this from seed? I have made several sowings, but failed. It does not germinate.—B. B.

2199.—**Insects in Seed Pans.**—Will any reader inform me by what means I can destroy the numerous insects which are in my seed-pans, &c., and which I have good reason to believe eat up the roots of the seedlings. Of the insects some are white and others brown. I have tried soot, but it does not kill them.—QUITE AN AMATEUR.

2200.—**Caterpillars on Cherry and Rose Trees.**—Can any one inform me of the best way to kill caterpillars on Cherry trees and Rose trees?—H. B.

2201.—**Propagating Sweet-scented Verbenas.**—Can any one give me directions how to succeed in striking cuttings of the sweet-scented Verbena? We have two large trees growing out-of-doors against a west wall, which are greatly admired, but we cannot succeed in striking cuttings.—W.

2202.—**Uses of a Hotbed Frame.**—I have a frame, 6 ft. long by 4 ft. wide, filled with stable manure, with an average temperature of 70° Fahr. What can I grow in it besides Cucumbers and Melons, &c? Will any fruit, or Rhubarb, or anything useful live, &c., in it. It is fixed in a slanting direction facing the south-west. Can any reader give me a little information regarding it? or else the frame will be of no service to me.—CONSTANT READER.

2203.—**Window Plants.**—Would some readers kindly give me a few hints in keeping plants in the room windows, and how often should they be watered? I should be glad if some one could give the names of four beautiful hardy plants for the window, which would grow tall enough to form a screen from the road. There is both gas and fire in the room. I have tried to grow Geraniums and Fuchsias, but never succeeded, as the buds always drop off before flowering. About three weeks ago, I purchased a Begonia and watered it occa ionally. The other day it seemed to be dying, and I took it to a friend to put it in his greenhouse, and a Fern also; and he told me I had given the Begonia too much water, and the Fern, kept it too dry. I have purchased a Musk plant, and should like to know what treatment it will require now, and when done flowering?—C. J. WRAITH, *Wakefield*.

2204.—**Summer Flowering Bulbs.**—Having found spring-blooming bulbs such as Scillas, Narcissi Crocus, and miniature Hyacinths, do very well in a Wardian case, open at day and closed at night when the gas is lit, I should like to know if there are any bulbs blooming in the summer, not more than 12 in. in height, to succeed them? They would not receive any sun.—THANKFUL.

2205.—**Diseased Peaches.**—The show of bloom on my Peach trees was good, and up to the last fortnight we had hoped to realise a fair crop. To day they are all either falling off, or they are marked with decay. The trees appear to be good and in full health. They have been well manured and supplied with water, as we think, sufficiently. They are planted in a lean-to house with ventilation at the back, and great care has been bestowed to give a regular supply of air. We are quite unable to account for their present state, and shall be glad to have the opinion or suggestion of some reader on the subject.—A. & Z.

2206.—**Outdoor Cultivation of Tomatoes.**—A few directions and hints on this subject would be very acceptable. Is there any chance of fruiting the Currant Tomato in the garden?—W. B.

2207.—**Heating a Greenhouse.**—I desire to erect a small lean-to greenhouse, 8 ft. by 5 ft., for forcing bloom for a conservatory. Would any reader kindly inform me how I may heat the same without using coal or gas, as both would be inconvenient?—G. H. I.

CATS IN GARDENS.

The Law on the Subject.—Some months ago I wrote at length on the subject of these terrible pests, feeling annoyed not only by their ravages, but by the fact that, while they almost swarmed in my immediate neighbourhood we were at the same time by no means clear of either mice or rats. I see that recently correspondents of GARDENING have been exercised by the plague of cats in their gardens; and in the number for April 3 "Major" prescribes the catching of them in a large trap with a falling door, and drowning them when caught. I just want to remind readers of what I pointed out in my former communication touching the law on the matter, which it will be well to observe. It applies—as I believe I then remarked—to the use of traps, as well as to the use of poison for the purpose. I recommended precisely the kind of trap advised by "Major;" but I added the caution that no strong-smelling bait should be used to entice the animals to the traps, whereby the party using such bait would (on proof thereof by any one aggrieved) be amenable to the law. Bait the trap with an ordinary bit of meat, a dead mouse or sparrow, or anything of the kind, but not with Valerian—that is, if there be any fear of discovery—and then whatever comes to the

trap is fair game. The typical case in the law books is that of "Townsend *v.* Wathen, 9 East, 277," and it is described as follows:—"Where a defendant caused traps scented with strong-smelling baits to be placed on his land, so near to the plaintiff's house as to influence the instinct of the plaintiff's dogs and cats, and draw them irresistibly to destruction, it was held that the defendant was answerable to the plaintiff for the injuries sustained, although he had no intention of injuring the plaintiff particularly; and it was also held that he (defendant) would be responsible for injuries sustained by any dogs (or cats) tempted from the highway or public paths to the traps on defendant's land, for he had no right to invite them there for the purpose of destroying them." Now, Valerian would unquestionably come under the description of "strong-smelling baits," at least so far as cats are concerned, for they are most curiously fond of it; and it might be questioned if a cat caught by it were caught as a casual or habitual marauder, or had been enticed by the special bait used.—W. H.

Edelweiss.—Much has been written of late about the Edelweiss, and very erroneous notions are given as to the rarity of the plant, the difficulty of finding it, and, above all, the difficulty of growing it. As a matter of fact it is quite a common plant in many regions by no means inaccessible, though all that is said about it will probably cause it to be exterminated in districts within easy reach of children who sell it to those who do not find it for themselves. The plant is quite easily grown, even as a border flower, in many well-drained soils; and in a rock garden it would be quite at home. Sometimes in our gardens it gets so large that it is not quite so interesting in appearance as it is on its native mountains. As regards beauty it is, though interesting, less remarkable than hundreds of other plants.

The Edelweiss.

HOME PETS.

Training a Young Hare.—A young hare may be most successfully brought up with a little care. If only a few weeks old, and it will not lap warm milk, some must be put in a small bottle, nicely warm, a small quill put through the cork, and then a small piece of rag put round. The little thing will suck that, but it soon learns to lap like a kitten and to eat bread and butter and biscuits. A large bird-cage makes a good house for it, and makes it tame also. It must never have too much liberty, or it will become wild. When older give oats, bran, and all nice green meat, especially Vetches, Clover, and Broccoli. The writer had one until it was ten months old, which had bread and butter or plain bread and warm milk all the time; but it had too large a run, and became so restless that she gave it its liberty when summer came. Its bed should be hay if in a cage, and sand if in a run. The writer's sat for months on a piece of carpet.—M. H.

Food for Tortoise.—For the past six years I have had a tortoise which came from Alexandria. It has had full range of kitchen and fruit garden. I observe it has a great partiality for Lettuce, Dandelion, and Strawberries. I never feed it in any way. About October it buries itself in the soil, and in April again turns out.—W. G. K.

Bullfinch with Injured Leg.—I have one with a swelling at the joint, causing him to carry it straight behind him. Being in an aviary, it is difficult to catch him to relieve the leg. Would it be better, therefore, to cut the leg off? If so, what part part of the leg would be the best, and what would be the best way to do this without injury to the bird?—HAMILTON.

Feeding Birds.—Can any one tell me the best kind of food for young thrushes and larks in the nest, and how often should they be fed each day?—J. M.

Canary Losing its Feathers.—Can any one tell me the reason why my canary loses his feathers and his tail?—J. R. [Probably he his moulting.]

Canary not Singing.—The canary in the possession of "Puss" is undoubtedly not in the perfect state of health it should be. A bird when indisposed is very like a human being in its fretfulness and depression, and you must not expect him to sing. You are treating quite right; but to restore him to anything like health you must administer a tonic, and I know of no other better than the Finchine, sold by Mr. Flory, Addiscombe, Croydon. I always recommend it to my brother fanciers, and they always find it admirably suited for the various ailments to which cage birds are subject.—A. D'A.

POULTRY.

Sitting Hens.—It is a curious fact, and one that shows there is no rule without an exception, that my best and most reliable sitters and mothers are old hens; one especially, quite seven years old, is one of the best in the world: I can trust her with the choicest eggs. Eleven full-sized eggs I hold to be enough for an averaged sized hen at any time; with more, it is not possible to distribute the heat of the body equally all over the sitting. Many of the instructions given as to treating sitting hens and feeding the young chicks are all nonsense, as is proved in the case of hens that steal their nests, and bring off a fine lot of healthy young. Perhaps my hens are less stupid than other people's, but when I sit one I just put the eggs into a corner on some soft straw, and put down the hen by the side of the nest, and she walks on and covers the eggs without further ado. I put water within reach, if she needs that at any time, but turn her off the nest every morning *nolens volens*, drop my pocket-handkerchief over the eggs, and see her out into the yard where she is fed alone, sometimes on Corn and sometimes soft food; and as soon as she has had a proper amount of exercise, is seen safe on the nest again; and this goes on from day to day until the chicks are hatched. Attention of this kind, even if not absolutely needed, is certain in results. During very hot weather, a gentle sprinkling of the eggs with warm water is useful, but during the spring, when the ground is moist, the heat of the hen will attract sufficient moisture from the earth. Failures too often result because the eggs are not fertile.—A. D.

Fowls not Laying.—"H. H.'s" Brahmas are too fat internally; consequently they lay imperfect eggs. Maize is not a suitable food for birds kept in confinement, as it is too fattening. Give each bird a pinch of Epsom salts; discontinue the Maize, and let them have as much exercise as possible.

Fowls with Swollen Beaks.—"Good Health" surely must be jesting when he asks what is the matter with his birds, and directly after tells us "they are very fat, eat well, and do not lay amiss." What more can any poultry keeper want, in the name of common sense? But respecting swollen beaks, here we are utterly at a loss to know what is meant. The beak is a hard, horny substance, and we cannot conceive a bird possessing any swelling on this. With regard to the colour of the beak and legs, we fancy this results from a cross with some yellow-legged game.—W. J. NICHOLS.

Unfertile Duck's Eggs.—We should advise "Pink May" to change the drakes, for, with two drakes to seven ducks, every egg ought to have produced a bird. If they have no water, sink one half of a good-sized tub in the ground, as it often happens that when ducks are without water to swim in, many of their eggs prove unfertile.

Keeping Fowls in Small Places.—In answer to Henry Cramp's queries as to the size of a run suitable for six hens and a cock, we say give the birds al the room you can posibly spare out of the small garden. The dimensions of the place must depend on the amount of space which can be allotted to the birds. The cheapest and best material for enclosing a run is galvanized wire attached to four or more posts, and the bottom consisting of loose earth. As you only want the birds for eggs, some common Spanish would answer best.

Fowls Eating Eggs.—Unless the birds are valuable it is best to kill them, for after having once learned to eat their eggs, there is no cure. The eggs, however, may be saved if the nest is placed a few inches from the ground and the bottom made to slope towards the middle, one board overlapping the other with sufficient space left for the egg to fall through on to some hay placed underneath to prevent it from being broken; or a cut made crossways through a piece of carpet fastened loosely across a basket with hay underneath will answer equally as well, the object being to get the egg immediately it is laid out of reach of the hen.

——I have broken one of my hens of this evil. I made a nest of wood with a round bottom; then sewed some hay twisted like a rope round the bottom, where there is a hole for the egg to drop through into a little drawer with a sloping bottom, with cotton-wool on so as not to break it. The egg rolls out of sight of the hen in which ever part of the nest it drops into. I could make one more simple by sewing a piece of coarse cloth into a box, with a hole cut in the bottom for the egg to drop out.—B B.

Brahma Hens Sitting.—It is impossible to say how long or how many eggs a hen will lay before showing a desire to sit. One will lay a dozen eggs and then become broody, while another of the same variety will lay the whole season through, and yet show no sympmtoms of broodiness. The large egg is a double-yolked one, and has nothing whatever to do with the hen's desiring to sit.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 3s to 6s; Azalea, 6s to 12s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 3s to 6s; Lily of the Valley, 6s to 18s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus (various), 4s to 9s; Pelargoniums (zonal), 3s to 6s.; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips. 4s to 9s: Violets (blue), 1s to 2s; Violets (Neapolitan), 4s to 5s; Violets (French), 1s 6d to 4s 0d. —*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Camellias, 1s to 4s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 6s; Roses (forced), 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 3s to 6s.

Plants in Pots.—*Per doz.*—Arum Lilies, 6s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Aralia Sieboldi, 12s to 30s; Ardisia crenulata, 18s to 30s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Clematis, 9s to 18s; Cyclamen, 6s to 18s; Daphne indica, 12s to 24s; Deutzia gracilis, 9s to 18s; Dielytra, 9s to 12s; Draccena (green-leaved kinds), 12s to 30s; Draccena 18s to 60s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Hyacinths, 4s to 9s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Narcissus, 0s to 00s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 12s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s. —*Per pair.*—Azaleas, 10s to 20s; Maiden-hair Ferns (large), 4s to 7s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts. per 100 lb, 120s; Grapes (English hothouse), per lb, 3s 6d to 7s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 6d.

Vegetables.—*Per* 100.—Asparagus, 1s 6d to 4s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips (outdoor), 3s to 4s; Radishes, 1s 6d to 3s; Herbs, 2d to 6d. *Per doz punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 9d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 5s; Chervil, per punnet, 0d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 3s to 6s Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

PARIS DAISIES.

THESE, known as French Marguerites, are among the most useful plants that an amateur can grow. The white kind, Chrysanthemum frutescens, is well known as being largely grown for supplying the London markets with flowers during winter and spring, and it is also largely grown on the Continent in flower gardens. We have also a small yellow kind named C. Comtesse de Chambord; but the best of all is the large yellow Marguerite, now being distributed by Mr. Howard, of Southgate, and which is named C. frutescens Etoile d'Or. It is said to have been raised in or about the year 1874 by M. Desgeorges, the then gardener to M. Adam, of Villa des Bruyères, Golf Juan, near Cannes; it was obtained from seed of Crysanthemum frutescens var. Comtesse de Chambord. As a garden plant this is one of the best, as it will grow in any soil, and flower profusely all through the summer and autumn, after which time if the

GROUP OF PARIS DAISIES (CHRYSANTHEMUM FRUTESCENS AND C. ETOILE D'OR).

plants are lifted and potted, they will flower all through the winter and spring in a greenhouse, when they may be again turned out-of-doors in summer. As a window plant too this is first-rate. It produces a constant succession of its large soft, yellow blossoms, which last in good condition for at least six or eight weeks. This kind and the white one only are perhaps worth culture, except variety be required, when, of course, the other kinds may be grown; and any one wanting two good hardy free-flowering plants for the garden conservatory or window cannot do better than secure C. frutescens and its yellow companion Etoile d'Or, or Golden Star. When grown in pots, a rather stiff soil, and not too large pots, will be best calculated to induce free flowering. All the kinds are easily increased by means of cuttings.

FRUIT.

GRAPE GROWING IN UNHEATED GLASSHOUSES.

THE time of year has now arrived when Vines growing in cool houses will be making progress. A few hints, therefore, as to the general management during the growing season may not be out of place. Now that the power of the sun is making itself felt, the grower must endeavour to utilise its rays to the fullest extent; and it is only by so doing that the owners of unheated Vineries can hope to succeed in ripening off a good crop of fruit. Many, too, whose glass structures are provided with a heating apparatus do not care to push their Vines into an early growth by its means, the consequence being that only in very favourable years do they obtain good well-flavoured fruit. From now onwards the golden rule should be to ventilate only when needful, varying the amount of air given according to the weather, shutting up the house directly the diminishing power of the sun renders it safe to do so. By following up this system throughout the summer and early autumn months, the necessity for employing artificial heat, either for starting the Vines into early growth or for ripening off the crop in the autumn, will be obviated; and, unless the summer should prove exceptionally sunless, the Grapes will ripen in a satisfactory manner. On bright sunny days a little air should be given at the top of the house some time before it feels the force of the sun. It is a great mistake to keep the structure closed until the temperature has risen some 15°, and then suddenly admit a volume of air. Such treatment, especially when often repeated, is productive of the worst consequences. The foliage, on the health of which the future crop depends, receives a severe check, rendering it liable to the attacks of the enemies to which the Vine is subject. On a debilitated and weakened leaf both red spider and mildew have but little difficulty in establishing themselves: for it is a curious fact—but one, nevertheless, familiar to most practical men—that insect plagues and fungoid diseases evince a decided preference for and fasten most readily upon foliage the tissues of which are in a more or less unhealthy state. Most greenhouses are provided with front sashes; these, however, need only to be opened on hot days. In a general way, excepting at this time of the year, opening the top ventilators will be all-sufficient; it is only in the hot summer days that the need for a free passage of air is felt. Abundance of air without draught is the maxim to be followed in the ventilation of Vineries. A cold current of air checks and chills, and induces a stunted growth. In the matter of ventilation, the grower will, however, have to be guided by the aspect of the house and the size of the glass. A structure facing the south and glazed with large squares will need a more free admission of air than one with an east aspect or glazed with small panes, or of which the woodwork may be of a heavy description. The Vine delights during its season of growth in a warm moist atmosphere; therefore, on closing the house early in the afternoon, well syringe the foliage and damp down the path. Red spider, one of the greatest scourges of the Vine, only appears in force when an arid atmosphere prevails, and cannot multiply when the proper atmospheric conditions prevail. When the Grapes are in flower avoid syringing heavily. The syringe should be provided with a spout, on which the operator should so place his finger that the water emerges from it in the form of a fine spray. In this manner every particle of the under surface of the foliage may be wetted without danger of washing off the pollen from the flowers. Be careful to use water of the temperature of the house, and see that it is perfectly clear. As soon as the Vines show flower, stop each flowering shoot close to the bunch, thus throwing back the sap into one leaf, which will then attain good size and substance. From the axil of this leaf a shoot will quickly form, which must also be stopped back to one leaf. By the time this leaf is well formed the berries will have set; consequently, shoot growth will not be so free. Laterals will, however, be continuously forming, and these must be pinched in as they appear. It is, nevertheless, as well to allow several of the terminal shoots to ramble freely after July; they serve to encourage root action, and help to maintain a free active circulation of the sap.

Before proceeding further, I would caution amateurs against the two free use of the syringe. It should be remembered that this instrument is merely a means provided for counteracting undue aridity in the atmosphere; therefore never employ it in dull, cloudless weather; and syringe early, so that every particle of moisture dries off by night. The syringe used with discrimination has great value; but in the hands of some it proves rather an enemy than a friend. Mildew, that worst of all enemies of the Grape grower, will quickly make its appearance when excessive use is made of the syringe. This pest, unlike the red spider, only comes when a too damp, stagnant atmosphere is maintained; it will, therefore, be seen that the Vine grower must at all times seek to preserve a happy medium, avoiding the extremes of aridity and saturation. The mildew, however, makes its approach in such an insiduous manner, and, when once in full possession, is so difficult to dislodge, that the inexperienced grower too frequently has to suffer great loss and vexation before he can destroy it. The best way is to hinder its approach, which may easily be accomplished in the following manner:—As soon as the berries are as large as No. 1 shot, mix up some flowers of sulphur into a paste, and then, having stirred it into a pail of water, syringe the Vines with it. It is not the great quantity of sulphur that is needed, but rather its equal distribution. A few grains on each leaf is enough. Be careful never to use black sulphur, the employment of which may cause the most disastrous consequences; and do not apply sulphur of any kind until the berries are fairly swelling. Many a crop of Grapes has been ruined by dusting or syringing with sulphur before the skin of the berry has become thick enough to bear its application. Rust, which sometimes disfigures the bunches to a serious extent, is the result of an injury inflicted on the berry when in a young and tender state. Sudden and chilling draughts of air, the too early application of sulphur, and careless handling when thinning, are the principal causes of its appearance. As soon as the berries are fairly formed thinning should be proceeded with. With the thumb and finger of the left hand seize the lowermost berry, drawing the bunch upwards, so that its position is reversed. In this manner each berry is distinctly seen, and the operation of thinning is thereby much facilitated. The inexperienced generally err in leaving too many berries, the result of which is that, not having space to develop, they are when ripe lacking in quality. The surest way for those who have had no great experience in this matter is to go over the bunches twice, taking out the smallest berries the first time. A season or two of practice is requisite, in order to impart the confidence necessary to enable the grower to complete the thinning at one operation. As soon as the berries begin to colour, air should be admitted more freely. In an unheated house, where the above instructions have been carried out, the first berries will be colouring by the middle of August. At that time of the year we are apt to get very hot weather, with still warm nights, in which case the ventilators should be left fully open. Nothing invigorates so much as the admission of night air when moist and balmy. Want of colour and shanking are often caused by undue exclusion of air during the colouring period; at the same time the grower must be guided by the state of the weather, and should, when the evenings are chilly, store up the sun's rays as much as possible by closing at an early hour of the day. During this period it is advisable to avoid syringing the Vines. If they have been well looked to in the manner recommended, the foliage will be clean and free from insect pests, which after this date are not troublesome. Damping down the floor in the evening may however still be practised. By acting upon the hints here given the amateur in his modest greenhouse may hope to produce fruit of the best quality without having to resort to fire heat at any period of the year. Before taking leave of this subject, I would, however, warn growers that care and attention must never be relaxed during the growing season. One week's inattention or negligence will suffice to undo the work of months. Paying the strictest attention to ventilating, varying the amount of air according to the weather, closing as soon as practicable—making, in fact, the freest use of the sun's rays—is the only way by which the owner of an unheated glasshouse can hope to ripen off a good crop of fruit.

J. CORNHILL.

Byfleet.

VEGETABLES.

Late-sown Scarlet Runners.—In autumn, when outdoor vegetables are comparatively scarce, a good crop of Scarlet Runners is extremely valuable, as they continue bearing long after the more tender French Bean is over. For this supply a good sowing should be made about the middle of June, and the plants should be treated in other respects exactly as those from earlier sowings are. They should be securely staked, as rough winds invariably prevail in autumn, and as sheltered a position as possible should be selected for them. It is too often the case that only one sowing is made in spring, and when the plants from this cease to produce pods fit for gathering the season is considered over; any one, however, who gives the late-sowing system a trial will, in average seasons, greatly prolong the gatherings, and will find the Scarlet Runner even more useful as an autumn than as a summer vegetable. It may be remarked that gathering the produce as soon as it is fit for use, and not allowing any pods to get old and seedy, is most important, as seed-producing is an exhausting matter, and soons bring the productive power of the plants to a standstill. Thin sowing is also advantageous. Upright rods securely fastened to horizontal ones make a good support on which to train the plants.—G. M.

Endive.—This is rarely grown in small gardens, but it forms a very desirable addition to the salad bowl in autumn and winter, especially if Lettuces be scarce or inferior. Sow towards the end of June (if sown early the plants are very likely to bolt before they are large enough for use) in drills 1 ft. apart, and when large enough thin out to 10 in. or 12 in. apart in the rows; the thinning may be planted elsewhere the same distances asunder. Sow again in July, and transplant the principal part in some open, well-exposed situation; the remainder should be planted in some open, well-drained, raised border. A few more may be sown in August if some shelter, such as a frame, can be found for them in winter. There are various ways of blanching them, viz., by laying boards or slates over the plants when they are full grown and quite dry; tying them up and placing inverted flower-pots over them, with pieces of slate over the holes at the tops to exclude light; covering them with dry leaves or coal ashes; or taking them up with balls of earth and storing them in a dark cellar—placing them, in fact, in any position not too damp to induce decay, and from which light can be excluded. Of course only a few should be blanched at a time, as this hastens decay, and they should not be blanched till they are nearly full grown. In other respects Endive requires much the same treatment as Lettuces. There are several varieties, but the Green Curled is the most useful.

Premier Runner Bean.—Although not quite so serviceable for small gardens as the

Scarlet Runner on hot porous soils, this Bean is worth a trial, being less liable to suffer from the attacks of red spider. It is a climbing variety of one of the Long-podded Kidney Beans, a vigorous grower, and bears long tender pods, not unlike the Canadian Wonder. It should be planted about the same distance apart as the Scarlet Runner, and requires staking in the same manner as that variety.

Second Crop of Broad Beans.—When Broad Beans have furnished their first crop it is usual, I believe, to pull up the stalks and throw them on the rubbish-heap. This should, however, not be done; for if they are cut down to about 6 in. from the ground, they will push up three or four stems instead of one, and yield a good second crop.—E. G. O.

Mildewed Peas.—All my Peas after the middle of May are sown in trenches prepared as for Celery. We take out a trench 18 in. or 2 ft. wide, and a good spade deep, and put in about 4 in. of manure, and dig it in. When the Peas show flower, if the weather is dry, we give a good soaking with water, and mulch the ground on both sides of the rows to the distance of 18 in. To have good late Peas it is necessary to water freely, dryness at the root being the main cause of mildew.—J. M.

The Best Late Peas.—Champion of England, Champion of Scotland, and Excelsior Marrow are fine varieties, the two last-named being best left untopped. I find Ne Plus Ultra to be one of the best for the latest crops; it grows vigorously and yields a long succession.—J.

Parsley for Winter.—The now well-known arched wire Pea-guards can be utilised for the protection of Parsley during severe weather if covered with a piece of oiled calico stout enough to throw off wet, which, as well as the covering material, should be kept off the crowns of the plants. To use these guards, however, to the best advantage, the Parsley should be sown in a row close by the side of a path where the covering could be put on and removed with facility. Seed sown in May would produce an abundance of leafage for winter use, and the plants need only be moderately thinned, as it is desirable to have as much foliage beneath the covering as possible. The protectors would, perhaps, not require to be used until after Christmas, and even then only during frosty weather, as whilst it is mild and open the plants will continue to grow. When hard weather sets in the protectors should be placed in a line over the plants, and over them might be laid old sacks, litter, or any dry covering, all of which will admit of easy removal when Parsley is required. Where there is room in Vineries, orchard-houses, and other places, an abundance of Parsley might be obtained if good strong single plants be lifted and put into 6-in. pots in time to be established before it is necessary to gather from them.—A.

THE RANUNCULUS.

The Ranunculus is now little grown in comparison to what was the case a few years back yet it is one of the most beautiful of garden flowers, and it is an excellent plant for the amateur to grow in pots in an unheated greenhouse. The following extracts from a pamphlet on the Ranunculus published a few years since by Mr. Carey Tyso, of Wallingford, Berks, will act as a good guide to those inexperienced in their culture. Mr. Tyso informs us that he has retired from business, but still retains a large collection of Ranunculi out of love for them, and is willing still to assist amateurs in making a collection.

The Ranunculus is a hardy herbaceous perennial, forming small tubers, about 1½ in. deep in the soil, and which goes to rest soon after flowering. There are innumerable varieties of this interesting species, above a thousand of which have received distinctive names, but they are for the most part of an arbitrary character. Large quantities have been annually imported from Holland, and from that source have been derived most of the varieties possessing strong and dark body colours. The Ranunculus is deservedly esteemed for the symmetry of its double blossoms, the brilliancy of its colours, and the great variety it displays. In a well-selected bed may be seen—scarlet, purple, crimson of every shade, yellow, white, and dark (approaching to black), with others which are denominated selfs; and bicoloured sorts with white, yellow, buff, or crimson grounds, beautifully edged, spotted, mottled, shaded, or striped, in infinite variety. The sight of a well-cultivated collection in full bloom presents a scene unequalled in the open parterre, and is well calculated to fill the spectator with admiration and delight.

Soil.—The Ranunculus delights in a rich hazelly loam. If, therefore, the natural soil of the garden be unfavourable, procure the top spit of a pasture, of rather heavy and tenacious but not clayey qualities, with the turf, and lay it in a ridge for some months, and turn it two or three times before use. It is deserving of remark that a pasture abounding with, and luxuriantly sustaining, the British varieties of Ranunculuses, or Buttercups as they are usually called, has also been found congenial to the Asiatic species. Decayed stable and cow manure in equal quantities, constituting together about one-third, added to two-thirds of loam, will when mixed and thoroughly incorporated, form a compost for the main depth of the bed; reserving a portion of loam sufficient to make a top layer of soil 2 in. deep, to which about half the above stated proportions of well-decomposed manure may be added. It is of importance that the tubers should not be placed in contact with fresh manure, as it engenders disease in the roots, and consequent injury to the plants.

Preparation of the Beds.—Having chosen an open but not exposed part of the garden, which will admit of the beds being laid down about east and west, remove the earth 15 in. deep, and from 3 ft. to 3 ft. 4 in. wide, and fill the bed with the prepared compost to within 2 in. of the surface; leave it thus for a month, then add the reserved top soil. These operations are best done in autumn, in order that time may be allowed for the earth to settle. Another method, where the subsoil is light and very porous, may be adpoted. Excavate the bed 15 in. deep, lay in the bottom 3 in. of

DOUBLE RANUNCULUS.

mingled manure and loam, and then saturate it with manure water. Cow manure well stirred in water will answer the purpose. Next add 3 in. more of compost, and saturate that layer; proceed to add two more similar layers, making 1 ft. deep in the whole, and after a week's settling add 3 in. of good healthy pulverised loam with but little manure, in which to plant the tubers. The surface of the beds should be level, and not more than 1 in. higher than the paths, in order that the roots may be kept regularly cool and moist; and as the Ranunculus thrives on a firm bottom, the compost should not be disturbed at the time of planting more than is just needful for that operation. During winter the surface may be pointed up rough, to take the benefit of frosts, but in no case should this be done more than 2 in. deep. The beds may be neatly edged with 1 in. boards painted lead colour, and in case named sorts are planted, should be numbered with white paint to correspond with the numbers entered in the amateur's list. As a bed well constructed at the commencement will admit of several successive plantings with an annual addition of fertilizing materials, it is worthy of the particular care of the cultivator, though the preparation at first may involve some little trouble and expense.

Planting.—The best season for general planting is the last fortnight in February—the plants have not then to contend with the severities of the winter. In some favourable seasons roots may be planted with advantage in October; they will have more time to vegetate and establish themselves, will make stronger plants, and will bloom more vigorously, and about a fortnight earlier than if planted in spring. Considerable hazard, however, attends autumn planting, and it is not recommended, except by way of experiment to those who possess a large stock and can afford to risk a portion. In fine weather towards the close of February, rake your beds perfectly level, and divide them into six longitudinal rows for mixed roots, allowing 4 in. from the outside row to the edge; or for named sorts, mark your rows transversely at distances of 5 in. asunder, and plant six roots in a transverse row. Draw drills with a small hoe 1½ in. deep, and plant the roots with the claws downwards, with pressure to secure them firmly in the soil, so as to be 1½ in. from the crowns to the surface. In order to secure a firm site for the tubers, some growers do not draw drills, but after raking the soil loosely, press the tubers with the thumb and finger to the required depth, and rake on them the surrounding soil. This can be done only in favourable weather, and when the soil is light and friable, and with attention not to break the claws of the tubers. When planting on a small scale, a dibble with a shoulder at the precise depth may be used, but in large quantities it is an inconvenient method, and planting at the bottom of a drill, with moderate pressure and without disturbing the subsoil, is attended with similar advantages to the use of a dibble, and in practice will be found to have some points of preference. If the top soil is light after planting, it may be gently beaten with the back of the spade; this operation, however, must be only done in dry weather, and may be repeated just before the plants come up.

(To be continued.)

Marigolds.—These should now be planted out in rich ground. In the mixed border they look best planted singly, and thus treated they make good bushy specimens. A little manure-water given during the summer greatly assists the production of fine flowers. The double pot Marigold, or, as it is sometimes termed, the Ranunculus Marigold, is a showy plant, the large golden flowers of which are very attractive.

Petunias.—The way to secure an effective bed of Petunias is by pegging the main shoots to the ground, and leaving the side shoots to produce a good surface of foliage, which should be pinched out occasionally to form an even mass. In this way a grand display can be had all the summer. Petunias are well suited for stone vases, beds and baskets, as they hang down over the sides, and form an attractive floral display.—E. A.

Wall Plants.—The beauty which the Wallflower now displays on many old ruins should encourage many to try to develop much more floral beauty in such positions. This is not only practicable, but easy. There is no doubt that with plants of the Wallflower order alone, we could easily convert dreary old ruins, or parts of them, into lovely little gardens. The Arabis and all such plants would thrive on walls, though they would not attain such size as on the level ground. Even the Irises, which at first sight one would never think of putting on walls, thrive thereon when there is a little soil for them to root in, as many may have seen on the Continent on old thatched roofs. There is no difficulty in establishing these lovely flowers.—H.

The Marsh Marigolds (Calthas).—Among the brightest of spring flowers are the various kinds of Marsh Marigold, which are now in full beauty about London. In addition to the common species (C. palustris) and the rarer variety C. radicans, there are the double-flowered forms C. monstrosa, bearing beautiful golden rosettes, and C. minor fl.-pl., a small-growing kind, a free flowerer, and a highly desirable plant. There are also C. leptosepala, the new Californian kind, and C. biflora, and another new kind, named C. purpurascens, a very distinct and handsome sort, which grows about 1 ft. high, has purplish stems, and bears a profusion of bright orange flowers, the outside of the petals being flushed with a purplish tinge. With these desirable qualities, we consider this

Double Marsh Marigold (Caltha palustris fl.-pl.).

last to be an acquisition, and one which is well worth growing.

ARRANGEMENT OF COLOURS IN BEDDING PLANTS.

It is rarely one sees the bedding plants in small gardens arranged so as to produce a harmonious effect of colour; a few hints on the subject may therefore be useful. The first thing to be arranged in a circumscribed display such as is possible in a small garden is a telling outline to the beds. This should be arranged by means of lines of plants presenting a strong contrast of light and dark, and of such colours as will harmonise well with all the other plants used. The best material for this purpose consists of foliaged plants. A distinct line of light colour will always rule, being easily seen; something light should therefore be chosen for outline. It is not well, however, to have a light outline at the very edges of beds; the third or fourth line from the front is preferable, unless in beds under 4 ft. across, when the second line will do.

The best plants for outlining beds are those with light sage-green or silvery-white foliage, as these harmonise with all colours. These should always be used where the beds are separated by gravel walks. When the beds are cut out on Grass turf other colours are as suitable. As a general rule, the darkest and the lightest colours used should form the outer rows, while the middles of beds should be filled to produce an effect of medium depth. The best effect for small beds is got when they are planted with three shades of the same colour, varying in depth, with one, or at most two, shades of contrasting colour, and a neutral—the leading colour occupying at least two-thirds of the space: as, for instance, an edging of dark blue Lobelia, a defining line of Cerastium, two lines of a very dark Lobelia, one of a full blue Lobelia with white eye, and one of a pale blue Lobelia; the centre, Amaranthus melancholicus ruber, kept dwarf. The same kind of arrangement will suit Phlox Drummondi, Verbenas, Pansies, and many other things—keeping always the darker shades near the light defining line. For Geraniums, the same arrangement will suit for larger beds, using the Centaureas as defining lines. A very good arrangement for a large bed would be—1, blue Lobelia; 2, Pyrethrum Golden Feather, and blue Lobelia plant and plant; 3, blue Lobelia; 4, Centaurea ragusina compacta; 5, mixed Petunias; 6, Centaurea ragusina compacta; 7, Perilla nankinensis; 8 and 9, crimson-flowered Geranium; 10, 11, and 12, scarlet Geranium; centre, rose or magenta-flowered Geranium. Intensly bright colours should be used sparingly, and the other shades should lead up to them. A bed of rich crimsons and reds, for instance, leading up to a few points of emphasis of intense scarlet, will have a richer and brighter effect than a whole bed of scarlets. Two flowers of the same shade of colour, but varying in brightness, should never be placed together; the weakest in colour is sure to suffer by the contrast.

Where the beds to be decorated are cut out on Grass turf, scarlet should be used very sparingly. The bright yellow-green of closely shaven turf in sunlight is the worst possible shade of colour to contrast with scarlet; the two colours damage each other, and both lose by the contrast. Nature never makes such mistakes, but produces whites, blues, lilacs, pinks, yellows, and russets, to contrast with the fresh green Grass; and by the time the flowers are in blossom, the blooms and seeds of the Grass furnish a neutral background. All pale colours may be used in bedding on Grass turf with impunity; the outer rows should be dark, but the defining bands may be white, rose, yellow, grey, or pale blue. For a small garden, a good plan would be to make the defining lines of two lines of Centaurea ragusina, and a line of Geranium vesuvius between them throughout, and use no other scarlet. Let all the beds be filled with rose, violet, blue, crimson, maroon, and brown, in various shades. In very large beds the defining lines might be made very broad, and the lightest lines of plants made to form circles or other patterns, bounded by the distinct lines of the defining band, which would really then be two parallel lines.

Where the space to be decorated admits of only a few beds, it is best to arrange a principal bed, with subordinates ones. It is well in such cases to link the beds together by making each supply what the other wants: as, for instance, in the simplest form possible, the centre bed might be too red by itself, consisting of red with a little blue; while the other beds might be too blue, being blue with a little red.

No decorative scheme of colour ever looks well if the colours are not carried through each other. There must be predominating masses of colour and subordinate ones away from them to carry the colour through the other parts of the design. Better, indeed, if this can be arranged in a threefold form, with the principal colours at least—that is, a principal mass, subordinate masses, and smaller patches subordinate to those.

Novel effects in ribbon borders and panel beds might be got at by adopting the old heraldic principle of counter-change—that is, say a red ground and a white figure; the next panel might be a white ground and the same figure in red. A modification of this arrangement, working the same figures throughout the border in varying colours, would afford scope to the ingenuity of the gardener, and might be tried with such plants as present a variety of colours with the same habit throughout—as Verbenas, Portulacas, Phlox Drummondi, &c.

For blues, purples, lilac, and violets—browns, bronzy greens, sage greens, white and bright scarlet, are good contrasts. For all rose and crimson shades—sage green, white, and plants with light yellow or white variegated leaves, are the most suitable. Yellows and oranges are the most difficult colours to manage; they should never appear in the same bed with scarlet, but may be used in defining bands with white, pale lilac, or sage green, where the most of the bed is deep brown crimsons, or purples, or Lobelias which have foliage and flowers dark.

J. D.

The Effect of Bedding-out on Gardening.—The older I grow the more I see that this system, in the way that it is generally carried out and in its consequences, is a lamentable mistake. I have at the present time some 300 ft. of glass frames of one sort or another devoted exclusively to common bedding plants, and we are are still short of room—all plants to fill a garden that my employer and his friends does not see, except for some three weeks in autumn, after making allowance for their absence during the shooting season and visiting. Could I use all this excellent accommodation, or even half of it, for growing early Roses, Violets, and multitudes of sweet, hardy, and other flowers that could be named, I could stock mansion and conservatories with the most *recherché* display, and provide no end of cut flowers, all of which are nearly crushed out. I could increase the supply of vegetables and fruit to a very great extent early in the season when these are scarce and dear, and make it all pay well, and yet without sacrificing the interests of the flower garden or rendering it less attractive, if the "system" was only changed, and I was allowed to remodel the designs of our garden and plant it differently. Gentlemen have not the least idea how much their flower gardens cost them, but their cost forms a large portion of the expenditure. My charge is no exception to the general rule. I am neither better nor worse situated than hundreds of others who have large gardens to manage with a large but still inadequate staff; but it vexes one to see how much good gardening is hindered or lost for the sake of an idea, and that a stupid one.—J. S. W., in *The Garden*.

Standard Pelargoniums.—Where these are desired, few kinds will be found better adapted for the purpose than the double-flowered Ivy-leaved varieties which have been lately introduced. They may be grafted on strong-growing scarlet kinds, seedlings being the best. The stocks should have a clean stem, which is easily obtained by removing the lower leaves until they reach the desired height; then in spring a piece of the kind to be grafted should be taken off with a heel; then with a sharp knife make an incision about 6 in. from the top of the stock, and large enough to admit the scion. Tie tightly with matting, so that the external surfaces come into contact, and there need be little fear of their becoming united. A few leaves should be left at the top of the stock to draw up the sap; but when the graft has taken fairly they may be removed gradually, ultimately cutting the stock off down to the graft. By putting four or five good branchy pieces of any of the Ivy-leaved varieties on to one stock, good plants may soon be obtained; as they grow they naturally assume a drooping habit, and when in flower are very effective. Mr. Kingsbury, of Southampton, grows them successfully in this way, and finds them useful for decorative purposes of many kinds.—S.

AMERICAN COWSLIPS.

(DODECATHEONS.)

THESE Primrose-worts grow in woods in North America, where they are known by the name of Shooting Stars. They are all perennial and perfectly hardy in this country, requiring a cool situation and light loamy soil; the nature of the latter is, however, of but small importance, as they grow as freely in peat or leaf-mould as they do in loam; situation is the principal point in their cultivation. In shady spots on rock-work, or in cool secluded nooks in borders. Dodecatheons will be found to soon establish themselves, and in spring to form lovely and attractive objects. All the species and varieties of this genus grow freely, and soon form large tufts, which require dividing every third or fourth year. The best time for performing this operation is the latter end of January or beginning of February, when the roots are becoming active, taking care not to divide them into too small pieces, as in that case there is danger of losing the plants while in a weakly condition. Dodecatheons may also be easily raised from seed, but this can only be obtained in very favoured situations. The following are all free-flowering excellent kinds.

Giant American Cowslip (D. Jeffrayahum).—This grows from 2 ft. to 2½ ft. in height, and has large dark green leaves, from 9 in. to 12 in. in length, furnished with conspicuous, reddish midribs. Its flowers, which are large and fragrant, and of a reddish-purple colour, are supported on stout stems that grow from 18 in. to 24 in. in height, and sufficiently strong to resist wind. In rich moist loamy soil, this plant grows vigorously in an ordinary border, but it succeeds best when partially shaded from the mid-day sun. It is thoroughly hardy, and one of the best of our border perennials. It is sometimes called D. lancifolium.

Common American Cowslip (D. Meadia).—This, the best known of all American Cowslips, has a beauty peculiarly its own, and whether grown in pots to bloom in a cold frame, in a house, on the rockery, or in the open border, it is alike a gem amongst spring-flowering plants. Clumps of it should be seen in every available situation wherever shade and moisture can be found. Well-grown masses of it may often be found with from ten to twenty stems, each bearing from eight to twelve flowers, and in the case of some varieties of it from twelve to thirty blossoms on a stem. The flowers, which are purplish-coloured and fragrant, are produced in umbels on erect, slender stems, which grow from 12 in. to 15 in. high. Of this there are numbers of pretty and distinct varieties, differing more or less in size of flower, colour, and height of plant. J. P.

The Entire-leaved American Cowslip (Dodecatheon integrifolium). — This, the most lovely of the genus, is one of the best rock plants in cultivation. Its foliage begins to make its appearance in March, and when well grown attains a length of from 4 in. to 5 in., forming deep green rosettes, from the centre of which rise the flower-stems, each bearing from six to twelve Cyclamen-like blossoms; the individual flowers are about 1 in. in length, and in colour a rich purplish-crimson, with a bright orange ring at the orifice of the corolla. As an exhibition plant this, in its way, is unrivalled, and as it grows freely and is perfectly hardy, it should be found in every garden. Strong, well-established plants of this produce abundance of seed, which should be sown immediately it is gathered.

American Cowslip (Dodecatheon Jeffrayanum).

NEARLY one million and a half copies of GARDENING ILLUSTRATED have been issued during the last six months—no doubt by far the largest number of any journal devoted to gardening or rural economy ever published in a similar time.

Rats in Gardens.—For some time past my garden has been infested with rats and mice. I tried several plans to get rid of them with traps, but could never catch one. A friend of mine advised me to get a bloater and split it in two and then across, and insert a little white arsenic and place it near their runs. I did so, and I am happy to say it killed dozens. I have not seen one for weeks. Whether they are all killed or left for another garden I cannot say, but they have left mine as if by magic.—GEO. CAME.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 24.—Re-potting variegated Pelargoniums and double and single Petunias for the autumn decoration of the conservatory; sowing Green Curled Endive between rows of Peas; also Curled Parsley, Rampion, and Cauliflower; planting Stocks, Asters, Malope; also spring-sown Cauliflower plants into manured trenches; also Vegetable Marrows and Ridge Cucumbers, affording them the protection of hand-lights or mats by night, and slightly shading them from the sun by day; refilling vases with summer-flowering plants; cleaning herbaceous borders; taking down coverings from fruit trees, and storing them away; tying and staking Dahlias recently planted, to prevent them being blown about by the wind; thinning spring-sown Onions, afterwards hoeing the ground between the rows; sowing Giant White Cos, Ivery's Nonsuch, All the Year Round, and Tom Thumb Lettuces; planting out first batch of Asters; planting out two rows of Celery; earthing up Potatoes and Broad Beans; mulching Raspberries with half-rotten stable manure; manuring and digging up ground for Cabbage, Savoys, and other winter Greens; making up fresh beds for Cucumbers; giving Plum trees on walls a good washing with Quassia-chip water to keep of green fly; tying up Lettuces to blanch.

May 25.—Sowing Bromham Hall and Golden Perfection Melons; also Telegraph Cucumbers; potting on Balsams and Chrysanthemums; looking over Rose walls, nailing in all the shoots that require it, and giving them a good washing to kill green fly; thinning Apricots, Peaches, and Nectarines, where not already done by the frost; earthing up Cauliflower plants; potting Poinsettias, Pinks, scented-leaved Pelargoniums, and Heliotropes; sowing American Red-top Turnips, Maize, Melons, and Victoria, Drumhead and Paris Green and White Cos Lettuces; planting out Tomatoes in warm situations; also Early Cabbage, Lettuce, and Cauliflower plants that were raised from seed sown in the open air; putting in Fuchsia cuttings, to furnish a batch of young flowering plants in autumn; pricking out Celery plants in very rich soil, and keeping them well supplied with water; removing Raspberries that have been grown in pots indoors to a sheltered border; earthing up Jerusalem Artichokes; thinning Carrots and Parsnips; washing Gooseberry trees with alum water to kill caterpillars, and syringing Peach and Nectarine trees with soft-soap and Tobacco water, to clear them of aphides; placing Cinerarias that have ceased flowering, and from which cuttings are required into cold pits.

May 26.—Sowing Autumn Self-protecting Broccoli, to come in for lifting and laying in in cold frames for winter use; getting all bedding plants planted out as fast as the weather will permit; digging out Celery trenches and getting the manure into them; sticking and earthing Peas; potting Chrysanthemums intended for standards into 8-in. pots; also re-potting Heliotropes and Verbenas, and placing them in the greenhouse; sowing another crop of Scarlet Runners, Veitch's Perfection, and Ne Plus Ultra Peas; also Parsley in well-watered drills, and Endive of sorts; planting Stocks, Asters, and Lobelias on Vine borders, and Lettuces among Seakale plants; pricking out Celery on rotten manure slightly covered with soil; preparing Broccoli land for late Peas; raking and otherwise cleaning rough shrubbery borders; cutting out dead Laurels, and removing overhanging boughs of trees and shrubs in pleasure grounds; plunging outdoor pot Roses in a sunny situation; nailing in leading growths of Peaches, Nectarines, and Apricot trees.

May 27.—Sowing Green-curled and Broad-leaved Endive, and Mustard and Cress; potting off Solanums, Celosias, and Lemon-scented Verbenas; pricking out Celery and Cauliflower plants; looking over British Queen and President Strawberries in the open ground, and picking off all the late and weak blossoms, so as to make sure of some fine fruit, and getting them netted; sticking Scarlet Runner Beans; cleaning out all catch-pools, and seeing that all drains are free, so as to be ready for heavy storms should they occur; potting Zinnias and Delphiniums, and placing them out-of-doors; potting off seedling Cinerarias, herbaceous Calceolarias, Amarantus, and Solanums; sowing Mignonette in 6-in. pots for indoor decoration; Red Globe Turnip, Cabbage seed for Coleworts; planting Vegetable Marrows and Ridge Cucumbers on prepared ridges, and re-filling conservatory baskets for the summer. Pricking off Carnation cuttings and young Celery plants. Training creepers on house-sides and on verandah; thinning Malope; dibbling in and watering Spinach seed where blanks have been caused in the rows; watering Celery, Violets, Radishes, Turnips, and all seed-beds; also Dahlias that are planted out; top-dressing Lilium auratum and preparing more places for Vegetable Marrows.

May 28.—Sowing Canadian Wonder French Beans and Radishes; hoeing amongst Gooseberries and Currants, and amongst all growing crops; dusting Turnips early in the morning with lime and soot to keep off the fly; potting off Celosias, Love-lies-bleeding, and Tree Carnation cuttings that are sufficiently rooted; sowing Mustard and Cress on well-watered beds; also Chicory, Syon House French Beans, Spinach, and another lot of Cucumbers; pricking out young Chinese Primulas and main crop of Celery plants; pulling up Wallflowers that have ceased blooming, and manuring and digging the land thus cleared for Stocks; clearing up superfluous bedding plants; hoeing among Strawberry plants and afterwards mulching them with short Grass; placing Primulas in cold frames, and shading them from the direct rays of the sun; nailing the leading shoots of wall fruit trees.

May 29.—Putting in cuttings of double Wallflowers and Alyssum; planting Snow's Winter White and Walcheren Broccoli; looking over Cucumbers and Melons, stopping them, and earthing them up where required; cleaning herbaceous borders; potting Tropæolum canariense into 6-in. pots for the decoration of wire stands, baskets, verandahs, &c.; shifting Balsams and Cockscombs into flowering pots; planting Tomatoes under wall in sunny situations; thinning spring-sown Onions.

Glasshouses.

Clematises, Passion-flowers, Mandevillas, Acacias, and similar plants now making growth freely, must not be allowed to receive

any check from cold draughts or from scanty supplies of water. The young wood should be judiciously thinned at an early stage, rather than severely pruned when further advanced. Tie in the young shoots gracefully and loosely, yet neatly, and never permit them to twine round each other. All free-growing plants must receive liberal waterings, no matter whether they are in pots or in borders; but at the same time let saturation in all cases be avoided. Remove such plants as have done blooming, and fill their places with flowering plants from pits or greenhouses. Plants that are stationary, such as climbers and subjects planted out, unless they are in flower, are greatly benefited by daily syringings; and if green fly, red spider, or other insects present themselves, a little Tobacco water, or water in which flour of sulphur has been mixed, may be efficaciously employed. Washing with a sponge or soft rag and water in which some soft-soap has been dissolved is the most effectual remedy for scale. Pot singly some of the best Lobelias into 4-in. pots, for the decoration of the window or greenhouse. Celosias, Gomphrena globosa, and the Amarantus salicifolius, should be shifted into larger pots than those they now occupy, as they increase in size; keep them in a moderately warm temperature and near the glass. Tulips, Hyacinths, Crocuses, Lily of the Valley, Spiræa japonica, and other plants that were forced into flower early in the season, should now be consigned to some shady border. Apply a mulching of loam and decayed manure in equal proportions to Lilies in pots, and, with the exception of such as are required for early flowering, keep them either out-of-doors or in cool frames. Keep early spring-struck cuttings near the glass in warm houses, shifting them when necessary. Keep Coleuses near the light in an intermediate temperature, and repot and pinch in their shoots as may seem necessary. Place old plants of Campanula pyramidalis out-of-doors, and keep seedlings of the same in a fair growing condition under glass. Keep up a succession of Mignonette in pots; a situation at the base of a wall shaded from the midday sun, and well sheltered, suits well-established plants perfectly; but in the case of seed-pots, and for some time after the young plants have made their appearance, they should be kept under glass.

Flower Garden.

It may be taken for granted that Calceolarias, zonal Pelargoniums, Verbenas, and similar plants have been already planted out; the putting out of more tender varieties may therefore now be proceeded with, such as Lantanas and Heliotropes, together with the various kinds of fine-foliaged or sub-tropical plants. Copious waterings must be given should the dry weather set in, and it is important that this should be done as late in the evening as is practicable. If it be administered in the morning or during the day, a large portion of the moisture supplied must necessarily be lost, as far as the benefit of the plants is concerned. A few plants of each variety of which the various beds consist should be retained in pots, for a time at least, as accidents sometimes occur, and a reserve force of this kind is often found to be useful.

Dahlias should now be planted. Those who set a portion of ground apart for them should on this grow the best prepared plants, which will be those that have been struck from cuttings, these being less liable to get crowded with shoots, and, consequently, produce finer flowers than plants that are obtained by dividing the old roots. Where fine flowers are required, the plants should stand 6 ft. apart every way. The ground can scarcely be made too rich. They should be well watered at the time of planting out, and at once secured by good stakes; but the stems should not be tied too tightly, so that their subsequent expansion may be allowed for. Round the stems for 1 ft. cover the surface 1 in. thick with sharp sand, so as to make it less agreeable for the slugs to travel over. A little Wheat-chaff or hard straw chopped up ½ in. long does much to impede their movements, for they object to travel over anything that sticks to them, and this is the case with these substances even when wet. The best of all for the above purpose, where they can be obtained, are the short clippings of bristles from brushmakers. Wet or dry, these are equally effective, and are too sharp for slugs to attempt to cross. Lime and soot dusted round the plants will stop the movements of slugs whilst dry; but, with moisture, it soon gets crusted, after which they will pass over it, and repeated applications do harm to the plants. The same material can with advantage be used round any other plants molested by slugs.

Hollyhocks. — Spring-propagated plants may now be planted out; they will flower in September and form excellent back rows to Dahlias, and will flower at the same time. The Hollyhock delights in a very rich deep soil, and it is well to put a mixture of fine loam and rotten manure round the roots of the plants. Tie the main stems to the sticks at once, and remove all side shoots with the fingers, in order to have a handsome single spike with large flowers. In planting, attention must be given to a judicious arrangement of colours. If the weather sets in dry the plants must be watered and mulched, to retain moisture.

We have tied up the flowering growths of Delphiniums, Phloxes, Pyrethrums, and all such hardy tall-growing subjects, to suitable sticks; the ground between the rows has been hoed over to destroy weeds. There has been plenty of rain, and it has not been necessary, as yet, to water at the roots, but if dry weather sets in we will do so, and mulch to retain the moisture.

Pansies in beds are in full flower, but to keep up a succession of fine blooms it is necessary to pick all the flowers off a certain portion. Surface-dress the beds, and peg the shoots close to the ground. In ten days the bed (if it had previously shown signs of exhaustion) will be a mass of vigorous growth and full-sized blooms.

Fruit Garden.

Melons.—Plants swelling off their fruit will require careful management as regards watering, as an overdose might induce splitting, whilst a meagre supply would be a sure precursor of red spider, which soon destroys the foliage, and unless this continues good to the last the fruit will be flavourless and insipid. It is therefore a good plan to cover the bed with non-conducting material, which, as a matter of course, prevents the too rapid evaporation of moisture and the necessity for frequent waterings. Elevate the fruit above the foliage in order that it may receive the full benefit derivable from light and air. Succession plants should be encouraged to make fruitful rather than free growth; plenty of air on all favourable occasions, with a medium amount of air moisture, will ensure the former, whilst a close, muggy atmosphere will as certainly ensure the latter, but there will be no fruit. Plant out for the late summer's supply, and make another sowing if the plants cannot be depended on for successional fruiting.

Gooseberries. — If care were taken in the winter to put lime on the soil round the stems of the Gooseberry bushes, as a preventive against caterpillars, little injury from these may be looked for; but in the case of any bushes that were affected last year without this precaution being taken, their reappearance may now be expected. When any can be found they should be destroyed at once, or they will spread and quickly denude the trees of their leaves, spoiling the present crop, and doing serious mischief by weakening the bushes for another season. A dusting of dry powdered lime sprinkled over the affected trees will, if fresh and caustic, destroy many and cause the rest to fall off on the ground, where they must be killed, or they will again crawl upon the trees. This should be done when there is an appearance of some dry weather; for, if wet, the lime will be washed off before it has had any effect. The most certain method for destroying these caterpillars is by using a mixture of white Hellebore (finely ground) and whitening, in proportions of 1 lb. of the former to 4 lb. or 5 lb. of the latter, mixing the whole well up and applying it with an ordinary tin flour-dredger, first wetting the leaves thoroughly with the syringe; the powder thus sticks to the foliage, and the caterpillars, feeding as they do on the edges of the leaves, swallow the compound, and it quickly kills them. In five or six days not a grub will be found alive, when the trees can be well syringed, in order to remove the powder from the fruit and leaves. The only objection to the use of this mixture is that, the Hellebore being poisonous, care must be taken that it is all washed off before the fruit is used.

Kitchen Garden.

Several of what may be termed half-hardy esculents will now demand special attention. Amongst these are Tomatoes, which should be hardened off preparatory to planting out on south borders or against walls at the end of the month. The same may be said of Capsicums and Chilies. Ridge Cucumbers and Vegetable Marrows may be planted out at any time, if they can be afforded the protection of hand-lights; and by way of starting them quickly into growth, a slight bottom-heat is desirable, and easily created by the use of lawn mowings and stable litter; about 2 ft. in depth will be ample, and as the material cools down the roots of the plants will soon establish themselves in it. Seedling plants of Thyme, Basil, Sweet Marjoram, and Sage, should be pricked out under shelter, and may be permanently transplanted in the open ground about the end of the month. All kinds of herbs have suffered severely, so much so, that new plantations of them will be a necessity, and provision should be made accordingly by pricking out a sufficiency of each sort. Sow Lettuces and Radishes once a fortnight; the former should now be sown where the plants are to grow, as transplanting in dry weather entails much labour in watering, and even if this be afforded the plants receive a severe check. Asparagus being now in full bearing, Seakale may be dispensed with; any yet covered should therefore now be exposed, and gaps in the plantation be made good by dibbling in sets made from pieces of roots 3 in. or 4 in. long. Salt is a valuable fertiliser for this esculent, and should be scattered over the surface after the ground is dug. Cut off seed-stems as produced, and thin the crowns to one shoot only.

Planting Celery. — Early-sown Celery should now be put out; if the trenches have been prepared beforehand run the hoe over the surface to destroy any weeds that may be vegetating. Give the plant a good soaking with water before moving them; remove them with as many roots as possible, and as much soil as will adhere to them. In moving Celery plants, there should never be occasion for the now almost obsolete practice of cutting off or shortening a considerable portion of the leaves at planting time; on the contrary, Celery, more than most crops, should never, throughout the whole course of its cultivation, from the time the plants appear above ground until they are fit for use, receive a check more than is inseparable from transplanting them, even when that operation is performed with care. If the trenches have been prepared for double or treble rows, put the plants in 1 ft. apart each way; if for single rows, 9 in. between each plant will be sufficient for ordinary purposes. In making the holes, use a planting trowel, and see that they are large enough to admit the roots without crushing them together; give each row a good watering as soon as planted. Celery costs more in manure and attention to grow well than do most vegetables, and it is worth while to treat it in a way calculated to produce it in good condition.

Leeks.—When indifferently grown, these are little better for the purposes for which they are required than Onions. To obtain the peculiar mild flavour which Leeks possess when large and freely grown, the plants must not be allowed to become stunted by being too close in the seed-bed; to prevent this, thin them out so as to leave them 6-in. apart.

Thinning Onions.—Spring-sown Onions should be thinned before they get too large. Take advantage of the soil being moist after rain to do this. If it be hard and dry, the limited quantity grown by many may be watered, so that the removal of any need not injure those that remain, which often happens when the ground is hard. As to the distance the plants are left apart in thinning, account must be taken of the kinds grown. Large kinds, such as Rocca or Nuneham Park, require double the room necessary for small varieties like Danvers or James's Long Keeping. If it be desired to grow well-developed bulbs of the large-growing kinds, these should be thinned so as to leave them 8 in. or 9 in. apart in the row; the smaller-growing, later-keeping sorts will not require more than half that room. Where some are required for pickling, a portion of the smallest-growing kinds may be left, unless they have come up very thickly, without thinning at all.

THE SHRUBBERY.

BIOTA ELEGANTISSIMA.

One great error that owners of small gardens commit is that of planting trees and shrubs the natural growth of which renders them unsuitable for such situations. Such free growing subjects as Lawson's Cypress, Thuja Lobbi, and gigantea, although very pretty and pleasing to the eye when in a young state, soon become a source of trouble when but a limited space can be assigned to their development; and the owner eventually has the mortification of finding that he must either so mutilate his specimens as to destroy their characteristic features, or remove them altogether. It is a matter for surprise that the slow-growing, neat-habited kinds of Coniferous trees should be so little planted in villa and small gardens generally. The monotonous aspect which the greater part of such gardens present during the winter months is really painful to witness, and is the more inexcusable as the choice forms of dwarf-growing shrubs are, as a rule, much more hardy and less susceptible of injury in severe winters than the masses of Laurels and such like evergreens which often form the sole winter verdure therein. Biota elegantissima, really a gem in its way, well deserves its specific designation; for, although of an upright compact habit, it is by no means devoid of that irregularity of outline which constitutes one great charm of the Conifer family. It has also the merit of changing its aspects at different seasons, the terminal shoots taking on in the autumn a bright cinnamon tinge, the effect of which is both novel and striking during the winter season. On the arrival of the bright spring days, the extremities of the shoots assume a most beautiful shade of yellow, glowing like gold in the sunlight, and presenting a most enlivening appearance. This Biota is indeed an elegant shrub, and worthy of a conspicuous position in the pleasure ground. For small gardens it is a most suitable subject, as, not being of a spreading habit, it does not cover much ground—an important consideration where space is limited. I would strongly recommend this shrub to intending planters, as I am sure that it only requires to be known to be appreciated. In a young state it is well adapted for window and balcony decoration, well-grown specimens in 6-in. and 10-in. pots proving very attractive. Within the last few years it has been extensively propagated in many nurseries, and considerable quantities of it are annually imported from the Continent, thus placing it within the reach of persons possessing only moderate means.

J. Cornhill.

Spring Flowering Town Trees.—These are just now so very beautiful that one could wish they were more plentiful in town gardens and squares. The blooming season of the common Almond is over. The snow-white double-blossomed Cherry is very beautiful, contrasted with the deep rosy flowers and crimson buds of the double-flowered Peach and the vivid scarlet Pyrus (Cydonia) japonica, Forsythia viridissima, rosy and crimson-flowered Ribes, Berberis Darwini, and the showy Amelanchier vulgaris are now very effective, as is also the deliciously-perfumed Magnolia conspicua, while Lilacs and Golden Laburnums already give promise of a magnificent show. In some suburban gardens the Rhododendrons and Ghent Azaleas are glowing masses of the most brilliant colouring always beautiful in fitful sunshine or when bathed in genial showers. One of the freshest and most effective of all spring flowering trees, however, is the Norway Maple (Acer plantanoides), which has been one mass of the most delicate golden-green flowers; and these, at a little distance, so closely resemble the tender young foliage that they might easily be overlooked. The Montpelier Maple (A. monspessulanum) also bears golden-green flowers, and both are invaluable for landscape effects in spring.—W.

Sowing Seeds.—Some correspondents appear troubled with birds which eat their newly-sown seeds. The principal seeds to suffer are Radishes, and the many members of the large Cabbage family. For the purpose of protecting these, simple and most effective guards may be used, one of which I find very useful, represents a bottomless tray, 2 ft. long, 4 ft. wide, 4 in. deep at ends, rising to 7½ in. in middle of sides. It is made of 1-in. deal board, about 7½ in. wide, which costs about one penny per foot; corners dovetailed, and strengthened by corner pieces, the top covered with small-meshed wire-netting, of commonest quality, which is made 2 ft. wide—hence width of frame. When the frame has had three coats of white paint it will last for years. I find two frames this size, and one other 4 ft. square, quite enough for all purposes, as all seeds are not sown at the same time; and when once they are up the frames can be put elsewhere. The seed-bed having been manured, dug, and raked smooth, the frame is pressed over it, leaving an impression of its four sides on the fresh soil, which impression will guide the sower within what limits to sow his seed. The seed having been sown thinly, some fine earth is sifted through a sieve over the whole bed, which is a quicker and in all ways a better plan than raking the seeds in. Then the frame is put over; and neither can birds peck and dust themselves, nor can cats or rabbits scratch. Added to this the sides of the frame give some protection to the seedlings from cold March winds.—W.

Sowing Lawn Seeds.—The ground having been properly prepared, and all stones picked out, take a narrow strip the whole width of the future lawn, and sow the seed on a mild calm day in early April. Then sift a little earth through the sieve (or rake seed in if the lawn be large and time is a consideration), and pat down the surface tolerably solid with a shovel, rendering the soil fairly hard (as in a newly-sown Onion bed), which will prevent the birds getting more than a tithe of the seeds, and in no way injure the seed. Then shift the board, sow another strip, and so on till the whole plot is finished. A slight frost after the seed has sprouted will not do much harm, as I discovered last April when I had ordered to be sown a piece of lawn, which, when just green, encountered a white frost every night for a week and yet was most satisfactory in spite thereof. But if some patches are rather bare, stand on a long wide board, so that the feet may leave no print, sow again and sift earth over seed without any raking, at the same time shifting the board over the whole lawn, and pulling up all Dandelions, Docks, Groundsel, &c., and removing any visible stones also. When the grass is about 4 in. high, stand on the board and cut piece by piece with a sharp hook, and then roll, after which the machine may be used, and a good lawn, by July, ought to be the result—S Piran.

Uses of Surface-stirring.—The necessity of the constant stirring of the soil can hardly be too deeply impressed upon amateur gardeners. It destroys the weeds, which exhale the moisture of the soil, with great rapidity. Ground thus often stirred, and loose, absorbs most of the water of showers, and retains it until much of it settles into the soil below; whereas, much of the water thus falling runs off rapidly from a hard surface. The mellowed surface becomes more thoroughly warmed than a hard soil by the noonday sun, and gives off its warmth more gradually during the night; and the plants are thus surrounded by an atmosphere warmer and of more uniform temperature during the whole twenty-four hours. But the greatest advantage of frequent stirring is that the loosened soil acts as a mulching, arrests the ascent of the moisture by capillary attraction, and keeps the soil in which the roots are acting moist. To secure this benefit of cultivating the land, it ought to be done just as soon as the soil becomes friable, after showers, whether there be any weeds to be eradicated or not. It is a mistake to suppose that the roots of plants are benefited by direct contact with air in the mellowed soil. Air is always injurious to them, and especially so if it be hot and dry. While the plants are growing, their roots should not be exposed to the air, nor should the soil in which they grow be disturbed. The full benefit of cultivation may be secured if it be only deep enough to furnish a few inches of fine and loose soil upon the surface. It is often said that the loosened soil absorbs moisture from the atmosphere, and thus aids the growth of plants; but every one can see that the surface dries much more quickly for being stirred, and it is very clear that what little moisture is thus received in the night is very quickly evaporated, and cannot reach the roots, or the soil in which they work.

GLASSHOUSES AND FRAMES.

GOMPHRENAS, OR GLOBE AMARANTUSES.

These Everlastings succeed well in sitting-rooms, in window gardens, and in other positions indoors; and the red and rose-coloured varieties, well grown and flowered, form chaste materials for the decoration of the dinner-table.

Gomphrenas may be sown at any time from January to July; the most common months for

Gomphrena Hoveyana.

sowing them are March and April. It is, however, a useful practice to make a sowing in May or June, as if plants the result of this sowing be well managed they will be found most useful for enlivening the warm conservatory stove during the two most flowerless months in the year—October and November.

As soon as the plants have become well rooted they should be potted off singly into 3-in. pots. When these are filled with roots shift them into the size in which they are to flower—6-in., or at the most, 8-in. pots; 6-in. is the best size, unless special and forcing culture be adopted. Gomphrenas look best in the form of single specimens and in small pots, and good plants of them for narrow shelves may be grown even in 4-in. pots. For such plants the soil must be light. A compost consisting of equal parts loam and leaf-mould, with a sixth of silver sand added, suits them admirably; 1 in. at least of drainage

Gomphrena globosa.

is needed in a 6-in. pot, and over the drainage a few pieces of rough leaf-mould will be found useful. In potting, care must be taken not to bury any portion of the stems of the plants. In the case of Celosias and Balsams, the practice of burying part of the stem is a handy method of at once securing a more compact habit and at the same time increasing the number and vigour of the roots. But this ruins Gomphrenas, as, sooner or later, it causes them to rot off. If Gomphrenas be grown in proper quarters and skilfully cultivated, they require no training; it is a useful plan, however, to nip off the first blossoms that show themselves on the tips of the stronger shoots, and it may also be desirable at times to stop a few of the stronger branchlets, or any that may get much ahead of the

others. When fully grown and coming into flower they may be placed in the conservatory, in which they will do well if neither over-watered nor placed in a cutting draught. A cool stove, however, or intermediate house suits the Globe Amarantuses best; in tolerably warm quarters the colour is brighter than it otherwise would be, and the plants continue to produce a longer succession of bloom.

The character of the flowers which they bear will be apparent from the annexed illustrations. The colours are bright red, rose, and white. The whole of the flowers of the Gomphrenas are not only ornamental while living, but almost equally showy when dead—and there are few dried flowers more useful and showy with which to form bouquets, along with other Everlastings and dried Grasses. Their colour in comparison with those of most other dried flowers may be said to be fast.

To preserve the flowers in a dry state in good condition for the longest period of time, it is important to cut them with a good length of stalk just before the flowers are fully expanded; the stems will then retain their stiffness and the flowers their form and colour. Slow drying in the shade is the best and surest preparation for perfect keeping afterwards. One sometimes sees heaps of Gomphrenas and other so-called Everlasting flowers lying on shelves and stages to dry like cut Grass in swathe in a hay-field. But those who collect and dry Grasses for ornament adopt a widely different method. There are few better modes of drying Gomphrenas than gathering them in small loose handfuls, with, as I have said, as long stalks as is practicable, and placing them in small empty jars, or pots, setting them in a shady part of the kitchen or other dry room until fully harvested. F.

The Scented Boronia (B. megastigma).

A Powerfully-scented Greenhouse Plant (Boronia megastigma).—Amongst the numerous Australian plants that we now possess for greenhouse decoration, perhaps none has attracted more attention than the subject of the accompanying illustration, not on account of the colour of its blossoms, which are far from showy, but on account of the delicious aromatic perfumed exhaled by them and the graceful habit of the slender branches on which they are produced. In its native habitat it grows about 2 ft. high, and has twiggy, erect branches on which, during spring and early summer, are copiously produced small bell-shaped blossoms of a maroon-purple tint outside and greenish-yellow within. It is a native of King George's Sound and neighbouring districts, and is one of the most desirable greenhouse plants with which we are acquainted. The plant that furnished the spray from which our woodcut was prepared was growing in Messrs. Veitch & Sons' nursery, at Chelsea, who have repeatedly exhibited this Boronia at the various metropolitan shows during the past few years. Though Boronias are what are termed greenhouse plants, they enjoy a little additional warmth during winter and early spring. Their culture is by no means difficult, the soil in which they thrive best being good fibry sandy peat, intermixed with a small portion of light loam: and, being mostly natives of barren, sandy localities, the drainage must be kept in good working order, as stagnant water about their roots is highly detrimental to them.

Speedy Mode of Propagating Tree Carnations.—In a nursery near London, where thousands of these plants are annually struck from pipings, it is an established rule never to prepare the cuttings, or pipings, as they are termed, with a knife. The plan adopted is to take hold of the top of the "Grass" and draw it gently until it breaks, which it will do at one of the joints. Cuttings thus treated are found to root much better than those made with a knife, which, unless very sharp and skilfully used, bruises the tissues and predisposes the cuttings to damp off. This mode of preparing cuttings is worth a trial, not only in the case of Carnations, but also in that of other plants which have distinctly articulated or jointed habit of growth.—B.

Tritonia aurea and its Varieties.—For late summer and autumn greenhouse decoration these plants are equal or superior to many that require a great deal more attention; those who have only seen the common T. aurea can have no idea, fine as that kind is, of the effect produced by an association of the varieties of different colours as they now exist—from white, orange, buff, salmon, to red and crimson. For cultivation in pots they need little different treatment from that usually given to Lilium speciosum, except that, being so much smaller growing, they require proportionately less room, and may be grown in larger numbers together in much smaller pots; but as to soil, potting, treatment from the time they appear above the soil in the spring through the summer up to the blooming period, and also when at rest in winter, the management that suits Lilies will do for them. They must be kept free from slugs and snails, as these pests have such a liking for the leaves that they riddle them completely, a mishap which has a very injurious effect upon the blooming and greatly impairs their appearance.

Gladioli.—These may be had in bloom in quantity in pots up to Christmas, but to come in at that time the planting should be delayed until June. If a small piece of reserve ground can be spared for them, well prepared and made moderately light, they may be lifted and potted when their bloom spikes are formed late in the autumn before sufficient frost has set in to destroy them. Doubtless this very late planting is not conducive to the well-being of the plants, and it might be urged on that account that the practice is not good; but effective varieties are now so cheap that they can be had for 2s. or 3s. a dozen or less; and even if after a single season's treatment such as this they are found useless, which is not likely to be the case, their culture would still be more economical than Hyacinth-growing; for, beautiful and indispensable as Hyacinths are, they are individually much less effective than the Gladiolus.

Genista fragrans.—This is one of the most useful free blooming and fragrant of the genus to which it belongs. Cuttings made of the young flowerless shoots put in now strike readily in a mild hotbed under a bell-glass. After being rooted, which will be in two or three weeks, they should be potted off singly into small pots, and returned to the frame whence they are taken, or placed on a shelf near the glass, where there is a genial temperature, so as to get them again into free growth; afterwards they had better be kept cool and airy. Attention must be given to watering and pinching, the latter requiring to be incessantly done, so as to lay the foundation of a bushy plant—treatment to which they submit more readily than any other plants with which I am acquainted. Before the small pots in which they are placed get full of roots, shift them into others a size larger, which will be sufficient for this year; avoid anything like what is called a liberal shift, as they do not require much root room, the aim being to get bushy little plants in as small pots as is consistent with their well-being. When well established and hardened they may be placed out-of-doors for the summer; but satisfactory results may be attained by keeping them in a cold frame to which air is freely admitted night and day, as thus protected they will be free from heavy drenching rains. They should be housed some time in the autumn before frosts occur, and be placed on a shelf as near the glass as possible; and if kept in a temperature of 40° or 50°, they will keep growing all winter, and by this time they will be throwing up their racemes of blossom, which ought, however, to be nipped off so as to encourage wood growth. In spring they will require another shift, which may be into 4-in., 5-in., or 6-in. pots, according to their size and strength. Treat them through the summer as just recorded, and by the autumn they will be fine bushy little plants, each shoot being laden with golden blossoms. With a little liquid manure given now and then at this stage they will bloom persistently throughout the winter and spring, answering well for almost any purpose for which flowering plants are required; and they can be placed even in draughty places with little or no disadvantage to their well-being. My plants of this Genista are just 2 ft. in diameter, and the same in height from the bottom of the pot, and full of bloom; shoots could be got off to form cuttings, which have to be taken from cut-back plants.—K.

Liquid Manure.—Having of late to find a remedy for sickly evergreens, as well as Rose trees, &c., and upon sandy soil, and knowing that urine is a very powerful manure, containing, as it does, the phosphates and sulphates of soda, potash, and ammonia, but that during the putrifying process much of this is lost by evaporation, I added a little sulphate of iron (copperas) to each gallon to fix the ammonia; it was thus soon ready for use, and its effect upon all weak plants is soon seen. If iron is not required, any other sulphate will suit: say sulphate of soda or magnesia; both are equally cheap.—A Public Analyst.

Cheap Roller for Grass Plots.—For many years I was at a loss for something to substitute for a garden roller (metal and stone being expensive); at last I hit upon one that answers admirably. I got an old iron oil-drum (damaged) at a druggist's—five gallon is a handy size. I took off the iron bands at the ends, and in the centre of each end I made a hole, run an axle of ⅝in. rod iron through, leaving 3 in. to project; had a blacksmith to make a handle of same thickness of iron, and the shape of an ordinary roller, for a trifle. I then filled it through the bung-hole with small stones, gravel, &c., mixed with Portland cement, which, as soon as it set, was fit for use.—Petros.

Beetles and Cockroaches.—These troublesome pests almost invariably congregate and increase rapidly in any heated structure to which they obtain access. They are often a great source of annoyance in forcing houses, where they attack fruit and also the leaves of various plants, especially those of young seedlings. I have lately tried several kinds of pastes and powders, but the most effectual remedy is strychnine mixed with barley meal, to which sufficient grease is added to make it into a paste. This, if set in saucers near their haunts, will be speedily cleared up, and the smallest portion will prove fatal to them.—J. G.

BIRDS IN SUBURBAN GARDENS.

If people would only take the trouble to watch birds closely for themselves, they would not form such wrong estimates of their injurious or beneficial operations in the garden. Although I live within a very short distance of the City, yet my garden, being old-fashioned and surrounded with plenty of trees, and close to two or three large commons, is frequented by a great variety of the feathered tribe; and I could spend many an interesting hour (if I had it to spare) in gaining information on the habits of our garden birds. This year I have been much surprised not to have heard the cuckoo; and I am almost afraid that the ever-increasing rows upon rows of bricks and mortar rapidly closing in around us on all sides has driven this bird further out. The willow-warblers are here in great force. The chiffchaff I heard on Good Friday for the first time, and the pretty song of the willow-wren about a fortnight ago from now (May 10); the reed warbler may also be heard all day long. These three tiny warblers are amongst our most useful birds, and may be seen actively engaged all day long clearing the tender foliage of minute aphides and blight, thus doing much good.

I have also seen a pair of bullfinches at work this morning, picking and devouring the apple buds as fast as they could. These handsome birds are, I am convinced, most injurious to fruit trees, as they may be seen to devour every bud indiscriminately; whereas the titmice, both greater tit, blue, and long-tailed tit, make an inspection of the bud first, and if they find it inhabited by a worm or maggot, will then pick it out. Thus, though both bullfinch and titmouse are devouring buds, the one is in all probability doing good, the other harm.

Swallows and martins are most useful birds, and deserve our protection and encouragement. All day long they are actively engaged in clearing the air of noxious flies and insects. The chimney or barn swallow is with us now, and has been for about a fortnight, but the house martin has not yet put in an appearance in this neighbourhood. It is curious how the swallows and martins seem to disappear again for a time, should the weather be very cold on their arrival. It is my belief that the disappearance is only seeming, for I have often seen numbers of these birds during bitter weather huddled together near mills and in sheltered places where they can find a few flies to subsist on; and as they take very short flights only, and sit together most of the time, they are, of course very little seen. We have a few swifts about during the summer, but I cannot find where they build about here, and I dare say they are only stragglers, as these birds fly very long distances and at enormous altitudes.

I have, as yet, seen nothing of the white-throat garden warbler, or fly catcher, all of which birds we have in summer. The black-cap is here, but the bitter east wind seems to take all the song out of him. He commences operations by clearing off all the Ivy berries he can find on his arrival, and will always first be seen where there is plenty of Ivy. We have plenty of chaffinches; they are well known for their partiality for pulling up seeds of all kinds as they appear above ground, but are also great insect eaters. We have great promise for Apples here. Pears show but little bloom; as is also the case with wall fruit. The dry weather seems to hold the slugs well in check. I suffered greatly from their ravages last year, but this spring I suppose they find it too dry and cold to venture out. In a dry spring, too, the birds do not find so many worms and insects ready to hand as in moist weather. and are therefore driven to hunt out the slugs and snails from their hiding places; and the blackbirds and thrushes will scratch away all the loose surface in their search, so that freshly-made seed beds should be protected from them. To those who possess gardens of moderate size I would say, Study your birds, and you will find much to interest you. Jardinier.

Peat Charcoal, House Slops, &c.—In reply to "Rustic," "Saxon Deyne," and several others in Gardening from April 1 to May 1, I would say there is no better fertiliser than peat charcoal; and soot and lime are nowhere as a preventive against insects where peat charcoal can be applied. Having used it for six years, I profess to know a little about it, as I not only use it in the garden, but in the farm to every crop, either alone or mixed with other manures. I have no wireworms at my Turnips or grey slugs at my Wheat, &c., and have very few diseased Potatoes where I use charcoal. Charcoal put into the tub of house slops prevents any bad smell. "Rustic" was highly favoured to get his charcoal for nothing; I pay 3s. per bag for mine.—T.

House and Window Gardening.

Mimuluses.—Improved strains of these have very large and finely marked flowers, and in most cases these are associated with a bold vigorous habit. Plants in pots grow and flower well in a half shady window, provided there is no fire in the room. If they be kept well supplied with water and occasionally syringed, they will keep effective for a considerable length of time. A pan of seedlings will give a succession of plants that will last all through the summer.

The Rock Strawberry as a Window Plant.—This little Strawberry, the botanical name of which is Fragaria indica, is an interesting little trailing plant, very suitable for growing in small wire baskets in windows. It bears an abundance of red berries, which, however, possess no flavour to warrant them being grown for eating. They are, nevertheless, very pretty in summer succeeding, the small yellow flowers, which are produced in abundance.

Rock Strawberry as a Basket Plant.

The plant may be easily increased by the runners which are plentifully produced. It will grow in any soil.

Annuals for Windows.—As a general rule the best soil for annuals grown in pots is a rich vegetable mould; about equal parts of good loam and leaf-soil will suit the greater part of them. It is necessary to be very watchful in regard to watering them, as, if allowed to become very dry when young, many annuals turn somewhat woody in character, or in other words get stunted; and when once they are allowed to get into that state, it is useless to attempt to put much further growth into them. Annuals in pots offer some advantages over permanent plants, for window decoration, as one does not regret throwing them away when done with, so quickly can they be replaced.—R.

Window Plants.—Windows filled with Scarlet Pelargoniums, Fuchsias, Saxifrages, and similar plants, always convey a sense of refreshing coolness to a room during hot weather, and it is indeed gratifying to witness the progress which this branch of cultivation has made of late years, and its beautifying effect upon both town and country dwellings. A plant should never be put into a dirty pot; on the contrary, all pots should be thoroughly washed, and not used until they are quite dry; otherwise in repotting, the ball sticks and the roots get mutilated. In the matter of drainage, the greatest care is necessary, as it is one of the chief points with respect to successful cultivation; and again, in watering window plants much care is likewise necessary, particularly in winter. When they are growing freely, however, they must be well supplied with water. On the other hand, to deluge them with water is equally a mistake. Enough should be given to throughly penetrate the soil, and no more.

ANSWERS TO QUERIES.

2141.—**Crown Imperials.**—Having regard to the fact that in suitable soil the Crown Imperial is usually as robust and blooms as freely as the hardier Lilies, it is just possible that bulbs heavily dressed with stable manure have been overdone with manure, and the excess of nutriment has induced rot. The finest blooms of these we have seen have come from bulbs left in the borders for many years, and the soil about them forked and manured in the ordinary way. On the other hand, it is an unfortunate fact that vast numbers of bulbous roots imported for sale seem to be bought only to die a lingering death—the check received in the importation proving a cause of decay that Nature cannot overcome. This is particularly the case with Liliums and Gladiolus bulbs. In any case, it were well to avoid all coarse stimulating manures.—D.

2136.—**Points of Good Pansies.**—Some information on this matter has been given at page 118, but in reference to seedling Pansies it is worthy of remark that first-class show flowers from these are so few and rare, even from the best strains, that, except where Pansies are grown as a speciality, it would be well to select the finest and most attractive flowers to stage if wanted for show. Good blooms of all kinds should be flat, well rounded, the edges of the petals even and smooth, and the entire flower stout and of good substance. Then, if of the fancy kind, work for size and fine heavy blotches, with rich deep colours. If of the old English or show strains, let the self flowers be pure and of the same hue throughout, excepting the blotch, which must be solid and black. The belted flowers should have the markings clearly defined, without any lines or streaks running out into the ground of white or yellow.—D.

2135.—**Stands for Exhibiting.**—Stands for the exhibition of cut flowers should be regulated in size chiefly by the size of the blooms to be shown. Thus Dahlias, Asters, and African Marigolds need larger stands than French Marigolds or Pansies; but in many exhibitions it is a rule to make the stands for all such flowers of the same size and height, to secure uniformity. For all practical purposes a useful size for standing twelve blooms of any of the above-named flowers may be 17 in. by 13 in., the holes for the blooms running crosswise in four threes This will give to each bloom a diameter space of about 4 in.; the proportions also are good. The depth of the stands must depend upon the way in which they are made. The kinds most in favour with our trade exhibitors of Pansies, Asters, &c., are made in the shape of shallow flat boxes about 2½ in. in depth, and regulated in size if for twelve blooms or for twenty-four blooms—a box for the latter number having six rows crosswise, seventy-four blooms each. These are about 16 in. wide, and 24 in. in length. These boxes are made of ½-in. deal, and all around the inside edge is a groove into which is made to fit a block-tin or zinc cover, having in it the required number of holes; and to these, on the under side, are soldered small tin tubes, which hold water. When this cover is placed into the box, and the whole painted green, a perfect stand is formed. Then lids, about 2 in. high, are made to drop over the stands, and are fastened with hooks. So secured, and kept on their bottoms, these stands may be carried with the blooms a long journey in safety. The boxes should be made quite flat, and when staged should be tilted behind with small wedges of wood, which the exhibitor should carry with him.—A. D.

2122.—**Origin of the Polyanthus.**—No less an authority than Mr. James Niven is of opinion that the Polyanthus is the progeny of the wild Cowslip (Primula veris), and florists invariably class all the section of garden Polyanthus under this botanical heading. It is a fact that the wild Primrose (Primula vulgaris) will, if fertilised with pollen of the Polyanthus tribe, produce a large proportion of Polyanthus flowers; but in its wild state, left to the operation of Nature, it never changes, and therefore there is little reason to suppose that it is the progenitor of the Polyanthus. In like way the Cowslip in a natural state does not change, but remains the Cowslip for ever. I very much incline to the opinion that all our garden forms of Polyanthus and Primrose have

come to us from the Continent, probably from Holland, and are the product of that incursion of the Dutch gardeners who came in with William of Orange and Queen Anne. How these originated the garden Polyanthus, and especially the beautiful gold-laced kinds, is one of the things history will fail to tell. In the same way the origin of the beautiful double Primroses is lost in oblivion; but it is noteworthy that the last member of this family, the new Platypetala plena, or Arthur Dumoulin, was raised in Belgium; and the charming bright fancy and duplex forms of Polyanthus seem to have originated there also. On the other hand, we see seedling progeny, of the very best forms especially, going back so far as to be even more worthless than the Cowslip; and this tendency to reversion shows a remote but exceedingly indifferent parentage. Whatever changes have been wrought in the Primrose and Polyanthus have have been the result of garden hybridisation. Nature fertilises, and so perpetuates her progeny, but does not hybridise; if she did, all original species would have disappeared long since.—A. D.

2147.—**Cowslips from Seed.**—Cowslips, under all conditions of place and growth, show flowers having both pin and thrum eyes. Pin-eyes are found in those where the pistil or stigma projects above the pollen, bearing anthers, the latter not being visible, but are far down the tube of the flower. Thrum-eyed flowers have the anthers well up in the throat, and the style or pistil is beneath. It is held by Darwin and other naturalists that in this section of floral vegetation the best progeny are obtained by inter-crossing the thrum-eyed blooms on to the pin-eyed flowers; and, as a matter of fact, florists find the best results from a cross of this nature. There is no assumption that these flowers are male and female, or sexual in any way; both are capable of self-fertilisation, and both produce seed. The real inference is that the united strength of two distinct plants, as found in the pollen of one and the stigma of the other, serve to produce the most robust progeny; and without doubt such seed is the most fertile. Probably it would be a good plan to lift from the wood a couple of plants of the wild Cowslip, one pin-eyed and one thrum-eyed, plant them in the garden, and, by means of a small camel's-hair brush, cross-fertilise as above described, and without doubt the seed will be fertile and produce good plants. Seed may be sown in a cool place as soon as well ripened, or in pans in a frame or cool house in the spring.—A. D.

2088.—**Treatment of Daphnes.**—Keep the plants in a greenhouse or frame until they have completed their growth. If the pots are very full of roots, the plants should be shifted into the next sized pot. Should, however, the ball of soil not be thoroughly filled with fibres, merely examine the drainage, and if defective, place the plant in a fresh clean pot of the same size. Many failures occur in the culture of this very fragrant greenhouse shrub through over-potting and defective drainage. A plant should never be shifted until the necessity for such an operation is seen to be imperative, as even root-bound specimens can be maintained in health and vigour by means of frequent waterings with soot-water during the growing season, or a top-dressing of some concentrated manure may be administered just as the plants start into growth. The best time for shifting is just as the growth commences—the soil to consist of equal parts of loam and fibrous peat, to be pressed in firmly round the old ball. Water carefully until the plants are fairly in growth, when a more free use of the watering-pot may be made. As soon as growth is completed, place the plants in the open air in a sheltered situation until the advent of cold, inclement weather. There is one item in the culture of this plant that must not be forgotten—*i. e.*, that it is extremely impatient of the knife: never cut away portions of the specimen, as the parts thus operated on often refuse to start again into growth.—J. C., *Byfleet.*

2139.—**Pot Roses to Bloom in August.**—The Hybrid Perpetual Roses will, if well attended to, flower twice in the season. The second time, however, the blooms will not be so fine, neither will they be produced in such abundance. As soon as the flowers fade, place the plants in a sheltered position in the open air until they have become thoroughly hardened. Then select a sunny situation and plunge the pots quite to the rims in the soil, leaving plenty of space between the plants, at the same time mulching them with some rich manure. In dry weather water freely, putting a pinch of soot in each can of water, and syringe the foliage every evening, or on hot, dry days. Keep a sharp look-out for mildew, dusting immediately with sulphur. By the middle of August a great crop of flowers should be formed, when if the weather is at all inclement, the plants may be placed where they can receive some protection. A cold frame is the best place, merely putting on the lights in stormy weather; or a framework may be made so that a piece of canvas can be drawn over when required.—J.

2081.—**Cinerarias after Flowering.**—In the case of unnamed seedlings, the best way is to save some seed from the best flowers and throw the old plants away. Free young seedling plants are as a rule preferable to the old stools, and, if grown along quickly, attain sufficiently large dimensions for decorative purposes generally. Named kinds should have the flower-stem cut off as soon as the flowers are faded, and the plants should be placed in a frame with a north aspect. Attend carefully to the watering, and sprinkle overhead in dry weather. By the month of August the offshoots from the crown may be taken off with a little piece of root attached. These should be potted separately in small pots, placed in a cool frame, kept close and watered carefully until they have struck root. Some of the pieces may not have roots, but if cut off with a sharp knife close to the stem they will soon emit some. As soon as it is perceived that the plants are making progress, give plenty of air by tilting the lights continually, withdrawing them completely in mild, overcast days and on still nights. Shift on as soon as the pots become filled with roots, pursuing the same treatment until it is time to place them in their winter quarters.—J. C. B.

2137.—**Roses on Seedling Briers.**—The Brier seed should be sown in March in deeply-stirred, well-manured ground. Strike out a bed some 4 ft. in width, make the soil level, sow the seed thereon, and cover with 1 in. of fine soil. Choose a fine dry day for sowing, and beat the surface down quite firm with a spade. During the growing season keep the young plants quite free from weeds, and water copiously should the state of the weather necessitate so doing. As soon as the early autumn days arrive, prepare a piece of ground in the same manner as already recommended, and about the latter end of September plant the young plants therein, in lines about 18 in. apart, placing the Briers some 6 in. from each other. If mulched with decayed manure, a strong healthy growth will be made, rendering them in good condition for budding when the proper season for this operation arrives. Bud in the ordinary manner, inserting the bud as near the ground as possible. The following season mulch well again with strong manure and water where required.—B.

2076.—**Annuals and Perennials for Rose Beds.**—Any of the hardy annuals, such as Nemophila, Clarkia, Collinsia, Leptosiphon, and Godetia, may be sown where they are to bloom in March and April. These will come into flower at an early period of the summer, to be succeeded by scarlet Linum, Mignonette, dwarf Tropæolums, and Convolvulus minor, seed of which may be sown from now onwards. The Honesty is a fine early-blooming subject, suitable for the centre of a bed. Seed sown now will furnish fine blooming plants next spring. Wallflowers may also be sown at the present time. In the way of hardy perennials, nothing is calculated to give more satisfaction than the many beautiful varieties of Viola cornuta and bedding Pansies. Seed of them may be sown now in a nice friable piece of ground, and the seedlings may be planted out when large enough to handle. Being of dwarf habit, they are suitable for placing in the front line, and if liberally dressed annually with good rotten manure and copiously watered in hot weather, will flower continuously throughout the summer. Lilies, such as the Tiger, Martagon, orange, and the old white, thrive, as a rule, much better when planted amongst other things. Their presence does not prevent carpeting the surface around them with other plants; on the contrary, they appear to thrive better when the scorching rays of the sun are thus hindered from playing upon the bare surface soil around them. They need, however, a good mulching to be applied in the autumn.—C.

2131.—**Plants for Winter Flowering.** One of the finest of winter-blooming plants is the Chinese Primula, of which many beautiful varieties now exist. A dozen or so plants of the white and red kinds, procured now and grown along, will alone suffice to render a greenhouse gay and cheerful throughout the winter. Then, again, there is the Cyclamen, undoubtedly the most useful of winter-flowering subjects, inasmuch as the same plants will last in bloom from October till May. Strong young plants potted now in a free light sandy soil will, if carefully attended to throughout the summer, produce a profusion of red, white, or pink flowers, according to the variety, during the dullest months of the year. Cineraria seed may be sown now; the plants, however, should be grown in a cool place, a frame on the north side of a wall being the best situation for them. Tropæolum Lobbi is an excellent winter flowering plant. Grow it on in the open air during the summer, picking off all bloom, stopping the shoots and tying them to a trellis. Allow the buds to form after the beginning of October. Sow Mignonette in pots in the middle of September: thin out to four plants in a pot. Grow along young Heliotropes, stopping them till the middle of September, then allowing them to go to bloom. Cuphea platycentra and Ageratum Cannell's Dwarf may also be managed in the same manner.—J. B.

2140.—**Cold Greenhouse.**—When Moss or green mould forms on the surface of the pots, it is a sign that the air in the structure is very stagnant, or that the soil in the pots is maintained in a too saturated condition. The very fact of the surface soil being thus covered would be enough to prevent the plants from thriving. Go over each plant and clean the Moss off, then allow each plant to quite dry out before watering again. A cold greenhouse should be provided with ventilation, both at the top and at the bottom, so that a free circulation of air can be maintained in favourable weather. If the structure is a north one, the plants will need to be frequently overlooked and cleaned, as where the sun comes so little, the air is more moist. If only ordinary care is exercised in the watering, no green mould of any kind should form from now on. Overhaul the plants, carefully examining the drainage. Where this appears at all defective, or earth has becomed mingled with it, take a clean pot of the same size (unless the pot is quite full of root, when it may be shifted), drain it well, and place the plant in it. This operation is often quite sufficient to restore a debilitated specimen to health.—J. Cornhill.

2083.—**Stand for Exhibition Flowers.**—Stands for exhibiting cut flowers are made in various ways. The simplest method is to make them much in the form of writing-desks, that is to say, gradually sloping towards the front. The dimensions have to be regulated by the nature of the subjects to be shown; thus a stand for Roses must necessarily be of larger proportions than that required for Pansies. The front board may be about 6 in. wide, and that forming the back portion should be about 10 in. in width. A case so constructed as to just enclose the stand without touching the blooms enables the exhibitor to arrange his blooms at home, and transport them in safety.—B.

2078.—**Non-flowering English Plants in India.**—I should imagine that in the case of the Wallflower the wood fails to become sufficiently hard and matured to admit of its forming flower-heads. The Wallflower never flowers so freely as when growing in rather poor soil, and subjected to the full force of the sun's rays during the growing season. It is a well-known fact that when treated too liberally, especially when the summer proves exceptionally moist, the Wallflower, even in its native country, is apt to run away too much to leaf, failing to produce bloom as it should do. I would therefore counsel your correspondent to imitate, as far as may be practicable, the natural conditions in which the plant thrives in a wild state. I would plant some on a raised mound in almost pure sand, and some I would keep in pots in a poor compost; at the same time I would ward off in some manner the heavy rains in the wet

season, thereby keeping the roots in a somewhat dry state, which treatment I am inclined to believe will have the effect of checking that rank succulent growth which appears to be the main cause of the plants not flowering. It is more difficult to assign a cause for the Sweet William not blooming, as this plant likes liberal culture; but I am inclined to think that if the plants were thoroughly established in an open position, not manuring them after the first year, they would in course of time flower. After the first year or so they would probably make a free succulent growth and would perhaps go to flower. The better plan would be to try some in pots and treat them in the manner recommended for Wallflowers, keeping them in a root-bound condition.—J. C., *Byfleet*.

2183.—**Gloire de Dijon Failing.**—Roses will suffer from mildew and curl if the roots are dry, and also from the opposite cause—excess of moisture. The one referred to is no doubt suffering from the first cause, and wanting water. Roses are gross feeders and will take up plenty of moisture, and during the blooming and growing season should have either manure-water or a thick top-dressing of short horse manure, the nutriment from which will wash into the soil with the waterings and feed the plants. Outer applications of sulphur may be of great service, but the great aim should be to prevent the disease rather than seek for its cure. —D.

2206.—**Outdoor Cultivation of Tomatoes.**—I have had good crops of the Currant Tomato in the open air; but, except for ornamental purposes, it is not so valuable as Criterion, or some of the large smooth kinds. Tomatoes should have a warm sunny aspect. The land should be in good condition, and be firmly adjusted round the roots of the plants. Plant against a wall, or fence if such can be had, setting the plants 15 in. apart, and training them to a single stem. If no wall or fence be available, then plant in the warmest spot at hand; a warm sunny bank sloping considerably to the sun would be an excellent situation. Plant in rows 2½ ft. apart, and 15 in. from plant to plant in the rows. Place a stake to each plant at once as soon as planted, and leave a little basin in the soil round the stem in case it should be necessary to water, which it most likely will. Keep all buds or shoots pinched or rubbed off from the main stems as soon as they show. Train up the leader regularly as it requires support. As soon as there is a cluster of flowers produced, pinch the leader one leaf beyond it, but take on the young shoot which breaks away until that also produces a cluster of flowers, when the leader should be pinched again, and so on until a good crop has been set, and the top of the stake has been reached. The latter should be strong enough to carry a good weight of fruit, and be about 1 yard high out of the ground. In hot seasons keep the plants well supplied with water. Mulching will tend to reduce the necessity for watering. —E. H.

2178.—**Growing Cucumbers.**—In a house of the size named, the best way to arrange the wires would be to fix permanently a stout iron rod at both ends of the house, about 16 in. from the glass, and strain wires from end to end horizontally, and to these tie the Cucumbers with soft Raffia or matting. Almost any kind of wire will do provided it be strong enough to bear the strain. Copper wire about the thickness of stout bell-wire will do; and it might be taken down when the Cucumber season was over and be stored away till the following year. The wires should be about 1 ft. apart; and should it be necessary to support a heavy crop of fruit they could be looped in the centre to the rafters. I am supposing the Cucumbers will be a temporary crop, and that at other seasons the wires would be in the way.—E. H.

2173.—**Road Sweepings as Manure.** —Road sweepings are excellent for all kinds of vegetables. For Celery, have it laid in a heap for a few weeks, and empty the house slops over it, turning it over once or twice. The best way to apply it is to dig it in; it also does well for mulching over the roots of all crops that require such assistance. It is not so rich as the manure from stall-fed cattle, as it is altogether minus the urine, which is the most valuable constituent. Use plenty of it, and the result will be satisfactory.—E. H.

2177.—**Pennyroyal.**—By the autumn Pennyroyal has become so dense and thick that the moisture lodges in it, and the wet and frost together often kill it. If a few roots are taken up in September, pulled to pieces and dibbled in thinly anywhere, but preferably in a dry border, such plants will sustain no injury. In very unfavourable situations some may be planted in a box, and be wintered in a frame or on the greenhouse shelf.—E. H.

2144.—**Rock Plants under Trees.**—We fear that little besides Ferns would thrive satisfactorily in the dense shade of a Beech tree. Many plants grow more freely in partial shade than when exposed to the full light, but the foliage of the Beech is so thick that flowering plants cannot live under it. You might try London Pride, the Wandering Jew Saxifrage, and the various kinds of Periwinkles. The situation is, however, suitable for most kinds of hardy Ferns, and we think that the best plan would be to devote it to their culture.—J. C. B.

2205.—**Diseased Peaches.**—This, as the trees are stated to be healthy, seems a difficult case to understand. Has there been any leaf-mould used in the border, and is the soil free from fungus? I should say either the wood was badly ripened, or that fungus had found a lodgment in the border, and that the trees were suffering from that cause and drought combined. When a border becomes infested with fungus, water seems to make no impression; it escapes away down a crack, or runs off the surface without moistening the disease-infecting portion where the white threads of spawn poison the soil and kills the roots. At any rate there must be a cause, and I should expect to find it in badly ripened wood, or fungus in the soil, or from a combination of the two causes.—H.

2165.—**Saving Wallflower Seeds.**—If the double varieties of Wallflowers mentioned are the old yellow or red perennial kinds, they will neither produce seed, or aid in the production of seed on other kinds. They are without fertile organs, and of course have no pollen. If the kinds alluded to, however, are of the German double and semi-double strains, then they may be trusted to produce seed that will again produce double flowers. None of the English garden single Wallflowers ever produce double or even semi-double kinds, and it is doubtful whether they would cross with the German doubles for any good purpose. A double Wallflower is usually a good flower spoiled. The fine red and yellow singles are both beautiful and rich in glorious perfume.

2184.—**Striking Cuttings of India-rubber Plants.**—Cuttings of the India-rubber plant when taken off should have all the leaves left on except those at the base, and should be allowed to lie, and dry the cut somewhat before insertion into the cutting bed or pit. The soil should be of fine loam, and a large admixture of sharp silver sand. A gentle bottom-heat is desirable, but at this time of the year the cuttings may root without, but of course less speedily. Keep the soil moist, but not too wet. A covering of a hand-light or a big bell-glass is desirable, as the leaves are then less affected by the surrounding dry atmosphere. —D.

2028.—**Celery Seed for Rheumatism.** —Celery syrup is said to be extensively used amongst German medical men with good results. The following recipe is translated from the German:—"Put 1 oz. of Celery seed into an earthenware jar with 1 pint of water; place in a moderate warm oven till reduced to ½ pint; strain it; take 1 lb. of white sugar, and put it into a clean saucepan with a cup of water; place on the fire till it boils, skim, and remove; add the decoction of Celery seed. A teaspoonful once a day." Perhaps this will suit "T. H." —R. K.

2181.—**Ants and Fruit Trees.**—Is "C. J. B." quite sure the destruction of his trees is due to black ants? I ask the question because some time ago my attention was called to what was thought to be a similar case, but which I found on investigation to be the work of the black aphides. The ants were present, but as an effect rather than a cause. The black aphides can be destroyed by dusting with Tobacco-powder; washing with a solution of Gishurst compound—3 oz. to the gallon. 2 oz. of soft soap and one quart of Tobacco-liquor to the gallon of water makes a good wash. Whichever is employed, perseverance in its use is necessary so long as a living insect remains. Traps and poison, as well as deterrents, may be employed for destroying the ants. They dislike tar, and a piece of rope dipped in tar and tied round the stem of the tree will prevent their ascending. A little may be smeared in the places where they travel; their nest should be found and destroyed by pouring in boiling water. To kill them, boil an ounce of powdered arsenic for half-an-hour in a quart of water, and thicken with sugar to form a syrup. Place it in their runs on shallow vessels, such as cheese plates, oyster shells, &c.; or any fragments of crockery will do. They may be trapped by laying bits of sponge about smeared with treacle. The pieces of sponge should be gathered with the ants on them, and thrown into boiling water.—E. H.

2202.—**Uses of a Hotbed Frame.**—A great many things may be obtained from such a frame, but, of course, not without labour. Rhubarb may be forced early, and so may Sea-kale; but when the produce has been gathered the roots should be taken out. Asparagus will force very well in such a frame. An early crop of French Beans may be had by planting in March; also Strawberries—either in pots, or the plants may be carefully lifted from the open ground with balls of earth, planted in the frame, and brought on gently at first. Tomatoes may be planted along the front of the frame inside, and trained over stakes or any kind of rough trellis, thinning and stopping the growths as required. In all cases success will depend upon the intelligence and perseverance brought to bear.—E.

2074.—**Aponogeton distachyon not Flowering.**—We should imagine that the plant in question does not get enough light and air. This water plant is of a hardy nature, and delights in full exposure to sun and air during the summer months. When accorded these conditions, it flowers freely.—C.

1965.—**Single White Camellias.**—The single white Camellia is not often seen in cultivation. It might be procured at some of the large London nurseries. It requires the same treatment as other kinds.—C.

2087.—**Raising Seeds.**—Bottom-heat is not absolutely needful for raising Cobæa scandens. The seed will come up in an ordinary greenhouse. Seedlings will bloom the same season, but the seed must be sown early in the year in a warm house, so that good, free, strong plants are ready for planting out in a cool greenhouse by the beginning of May. We suppose you refer to a cool house species of Loasa, which demands the same treatment.—C.

2032.—**Soil for Rhododendrons.**—Rhododendrons would thrive in soil of an alluvial nature, but they will do much better if a good portion of leaf-mould or some sound loam be mixed with it. The growth made in soil destitute of organic matter is generally rather weak, and the foliage does not attain such handsome proportions.—J. C.

2172.—**Watering Early Potatoes.**—Potatoes in which curl is seen in the leaves are probably suffering from drought, especially as the weather has been dry for so long. A thorough soaking of water would do good, but it should be given in the morning, so that the foliage might dry again before night, lest white frosts should injure it. A sprinkling of guano or other artificial manure, given before the watering, would have a beneficial result.—A. D.

2198.—**The Feather Grass** (Stipa pennata).—Seed of Stipa pennata that does not grow is probably old and worthless. Owing to the wet summer of last year there is a great scarcity of new seeds of many plants, and no doubt Grasses suffered amongst other things. Try and get fresh seed elsewhere, and sow again.—D.

2194.—**The Best Pansies.**—The following are six good English or show Pansies:—Elizabeth Thompson, white self; Beacon, dark self; Mrs. Horseburgh, white self; Leah, white ground; and Robert Burns and Mrs. Russell, yellow ground. Six good fancies are Miss Melville, Sir W. Scott, Mrs. R. B. Matthews, Mrs. Grainger, Von Moltke, and Marigold. What kinds are best must be more a matter of opinion than one of fact.—A. D.

2201.—**Propagating Sweet-scented Verbenas.**—The sweet-scented Verbena (Aloysia citriodora) or the Lemon plant, may be propagated from cuttings taken from the old wood in March, or the young shoots when firm in August; in either case, cover with a bell-glass and shade from bright sunshine. Let the soil be a mixture of loam, leaf soil, and sharp sand, and sprinkled well before the cuttings are inserted.—A. D.

2171.—**Blight on Apple Trees.**—Anoint all the patches of blight with paraffin oil, rubbing it in with a painter's brush, but keep it away from the young growth. Use the garden engine freely. I have no doubt this pest might be eradicated with a good supply of cold, clean water, applied forcibly through the garden engine once or twice a week in summer.—E. H.

2187.—**Growing the Bush Marrow.**—Train the main stem to a stout stake, and cut the fruit when large enough for use. Lay a mulching of half-decayed manure round the stem when the plant has made some growth, and give plenty of water in dry weather. There is no difficulty in their culture.—E.

2189.—**Manuring Parsnips, &c.**—Parsnips and Carrots are best grown without manure at planting, as it

tends to make the roots forked and deformed. If the land is very poor, liquid manure, after they are hoed and thinned out, will be beneficial; and also to Turnips. The latter may have a top-dressing of super-phosphate, about 5 lb. to the square rod.

2167.—**Grafting Plums on Apricot Stocks.**—If the roots of the stock on which the Apricot was originally budded are healthy, the top of the latter might be cut away down to the original Plum stock, and Plum grafts inserted therein. Coe's Golden Drop, and Transparent Gage are good varieties. The result will be successful or not, according to the state of the roots. It is too late to do it this season.—E. H.

2188.—**Wireworm in Gardens.**—Catch and kill them is the best advice I can offer; and to this end place pieces of Potatoes and Carrots just beneath the surface in various parts of the garden and examine them daily. This is a slow but a sure remedy, and the cheapest and best I know. Persevere.—E. H.

2145.—**Yellow Spots on Geranium Leaves.**—Allow the plant to dry out, then shake away as much of the old soil as is possible. Replace in a fresh pot of the same size, using some nice sandy soil. Place in a light well-ventilated situation, and water carefully. The roots are in a bad state; hence the unhealthy condition of the foliage.—B.

2151.—**Jasmines not Flowering.**—If the plant in question is the Jasminum fruticans or J. humile, shift it into a larger pot, and place it in a sheltered situation in the open air until settled warm weather, when it should be placed in a warm sunny position. Water freely, giving a little liquid manure. It should bloom during the summer or early autumn months.—J. C.

2176.—**Soot-water in Vinery.**—Soot-water will not cause rust on Grapes or otherwise injure them when sprinkled on the borders, &c., and the practice may be safely continued so long as moisture is required. Avoid wetting the pipes when they are hot.—E.

2174.—**Nitrate of Soda for Plants.**—Nitrate of soda is rich in nitrogen, and may be usefully given to growing crops at the rate of 1½ lb. to 2 lb. per square rod; it should be sprinkled between the rows of plants in spring. It is all used up in one season: nothing is left for a following crop. It is a valuable stimulant for the encouragement of rapid growth.—H.

2084.—**Gnats Stinging.**—Tobacco is one of the best preventives. A small piece of Caxillar bark burned is also a good thing.—R. K.

2208.—**Pelargoniums not Flowering.**—I have struck some Pelargoniums; they are very healthy plants, but have very few heads of bloom. Why?—K. C. [Place them in a sunny position, and they will flower more freely by-and-bye.]

2209.—**Questions on Vines.**—Is turfing-over of a Vine border injurious to the Vines? How often should the border have water applied, and what kind of manure water is the best to use? Should air be given to the house by the front sashes and at top? Is syringing or steaming the house good at this season? Is stripping off the bark from canes, when it is not loose, hurtful?—R. M. B. [If the border is a good one, and not likely to require any addition in the way of fresh soil, it might be turfed over without any serious injury to the Vines. The best manure water would be the drainage from a manure heap, but any kind of liquid manure will do for Vines if properly applied. As to when the border should be watered, that must depend upon the weather and the drainage of the border. If well drained, you are not likely to over-water it. Syringing the wall and wetting the floor is necessary at this season (except the Vines are in bloom), but steaming is not to be commended. Stripping the bark off Vines when not loose is bad practice.]

2210.—**Moving Roses.**—I have a fragrant white Rose which I wish to remove elsewhere. When can I do this so as not to injure the bush, or to prevent its producing flowers?—K. K. [Move it in autumn, or early in spring.]

2211.—**Vegetable Marrows on Walls.**—Would a Vegetable Marrow succeed trained against a wall where it would receive a considerable amount of sun during the day? Above the wall there are iron railings, which get very hot during the day; would it be advisable to carry it on to the railings? The ground is well manured. —DIZZY. [A Vegetable Marrow would grow in such a position, but the fruit would require some support to prevent them breaking down the plant.]

2212.—**Australian Cress for Bedding.**—Can this be used for carpet bedding?—J. K. [We should say not; the Cress only lasts a few weeks before it runs to seed.]

2213.—**Plants for Carpet Bedding.**—Will Alternantheras grow about Bradford; it is a very smoky place? Also, what would you recommend for carpet bedding to plant with Alternantheras? My garden has a north-eastern aspect, and I do not get much sun after mid-day. —G. H. [If planted in light rich soil, and kept well watered, Alternantheras would grow fairly well. To plant with them, you could have Lobelia pumila, Mesembryanthemum cordifolium, Golden Feather, Mentha Pulegium, Cerastium tomentosum, &c.

2214.—**Treatment of Camellias.**—Will it be advisable to plunge Camellias in the full sun, or put them the north side of a wall in the pots as they are?—CONSTANT READER. [An open airy place is the best; but the sun must not be allowed to shine fully on the plants. Behind a north wall would do well.]

E. M. M.—The yellow matter on the Rose is a fungus very common to the Rose. We know of no effectual remedy.

Gardener, Bridge House.—Apply to Messrs. Sutton & Sons, Reading, Berks.

Newspaper Shading.—*Press.*—Newspapers will do very well to shade plants from hot sunshine, but they should be movable.

How to get rid of Black Fly in Cucumber Frames.—*E. J. I.*—Fumigate them in the evening with Tobacco or Tobacco-paper. Do not fumigate too strong at a time; rather do it three or four successive evenings.

Arranging Flower Beds.—*G. Dawson.*—Much depends upon the plants you have at your disposal, and the nature and shape of the beds and borders you wish to plant. You should visit other gardens, and then form plans for yourself. It is difficult to advise you in print.

Planting Briers.—*R. K.*—These should be planted in autumn and budded the following summer. Any Roses may be budded on Briers. Your question as to naming red and white Roses is so wide.

Sphagnum Moss.—*Mrs. S.*—This is easily procured from the firms who advertise garden requisites in our columns weekly.

Peach Trees.—*I. H.*—Your trees are covered with brown scale. You should clean it off as much as possible with a small stiff brush and when the leaves have died off, paint the trees over several times during the winter with seal oil. The best book on cool house fruit we know of is River's "Orchard House."

Constant Contributor, Oldham.—We do not exactly understand the position in which you wish to grow plants in your bed-room, but there is no reason why you should not try. Your own experience will prove your best guide. Geraniums, Fuchsias, Musk, Mignonette, &c., might be tried. A dozen plants in a room would have no very injurious effect upon its inmates, we should say.

Spot on Geranium Leaves.—*J. A.*—The leaf sent is very thin, and has apparently had very little air given to it. Let the plant get thoroughly dry before you water it again, and give plenty of air.

Creeping Jenny.—*Dizzy.*—Lysimachia Nummularia.

Dracæna terminalis.—*J. H. B.*—This and other kinds of Dracænas can be got in plenty in Covent Garden, or at any good nursery, at a cheap rate.

Soil for Coleus.—*Victor.*—Light sandy loam, and leaf-mould in equal parts, will grow Coleus well.

Primroses.—*Victor.*—Apply to Mr. A. Dean, Bedfont, Hounslow.

W. W. I.—The back numbers you ask for would be 2s. 3d., post free.

Glazing without Putty.—Apply to T. W. Helliwell, Brighouse, Yorkshire; or 19, Parliament St., London.

"Hygeian Cook Book."—Apply to Trübner & Co., booksellers, Ludgate Hill.

Shaw's "London Market Gardens."—*F. T. S.*—The price of this book is 3s. 9d., post free.

QUERIES.

2215.—**Cropping a Kitchen Garden.**—I have enclosed about half an acre of good stiff ground, which I intend to devote to the growth of Cabbage, Cauliflowers, Broccoli, and Celery, and shall be glad to know which are best sorts to grow for succession. I have now plants nearly ready for planting out, consisting of Enfield and Nonpareil Cabbage, early Drumhead Savoy, and Veitch's Giant Cauliflower; also some Broccoli, but I do not know of what kind. What shall I sow to follow them for autumn and winter use? and what is the best sort of early spring vegetables and which is the best kind of Celery to grow. I intend to raise my own plants. —W. M.

2216.—**Roses not Flowering.**—I have a small unheated greenhouse in which I grow nothing but Roses in pots. I have a La France, Boule de Neige, Alfred Colomb, John Hopper, Marie Baumann, Jules Margottin, Louis Van Houtte, and Duke of Edinburgh. The first two flower well, but very small; the others do not flower. I give plenty of air and liquid manure. I think the soil they are in is good. I have also in the same house a Maréchal Niel and Gloire de Dijon; they do not flower, and the Maréchal grows very weakly. I live in a town, but not a large one. Why do not my Roses flower?—TOM TIT.

2217.—**Grubs in Potato Land.**—I have a piece of ground, that has for many years been in Grass, turned up this season and planted with Potatoes. I find the ground is infested with a kind of grub about 1 in. long, and of a dull leaden colour, called by some the turf grub. Can any reader tell me if the grub is likely to attack the Potatoes? and if so, the best way of guarding against its attacks?—N. K. J.

2218.—**Ammonia for Pot Plants.**—What quantity of strong liquid Ammonia is sufficient for, say, 1 gallon of water for pot plants, and how often should it be applied?—LAMBETH AMATEUR.

2219.—**Growing Dates.**—Having often found Date stones (thrown on garden with shop sweepings) germinate, I potted some, and put in greenhouse to winter, but in the spring they died. Last summer I put some stones in a pot in light soil; they produced a single blade about 6 in. long last autumn, but have made no further progress, and look unhealthy. Can any one inform me how to treat them, and if the Palm they produce will be at all desirable? The spike the stone throws up is exactly like that of a Gladiolus.—J. BUSSEY.

2220.—**Succession of Flowers for Window Boxes.**—I have some flower boxes in my windows that I wish to keep filled, as far as possible, with flowering plants all the year round, changing not oftener than three, or at most four times in the year. Would any one suggest a rotation for the different seasons? The flowers, being in pots and not loose in the earth, could be removed at any time.—J. A. E.

2221.—**Mushroom Growing in Meadows.**—I have got a meadow of nearly three quarters of an acre, the ground of which is moist but not wet. Is it possible to insert some Mushroom spawn, so as to grow Mushrooms during the coming season?—J. W. BATCHELOR.

2222.—**Growing the Cocoa-nut.**—Can any one tell me what temperature, &c., is required to start a Cocoa-nut into growth, and what the best time to try it? I have seen them grow in shop windows in Chicago, U.S.A., but never here.—J. BUSSEY.

2223.—**Apricots in Glass Sheds.**—In No. 3 of GARDENING ILLUSTRATED of last year, a brief description is given of Apricot culture under a glass shed in Nottingham. I would like to ask how the system has answered during the last two critical seasons we have passed through; and if a construction made in the lean-to style would answer the same purpose, with dwarf trees instead of standards; and if it would be safe to remove the glass from the trees—say from November till the trees wanted protection in spring. It would simply be a lean-to shed without a back, having wooden ends, the glass lights resting on 9-in. pillars at the bottom, and wood posts at the top; the situation cold—in the county of Durham.—S. B.

2224.—**Vine in Conservatory Not Doing Well.**—Can any one tell me the best way to proceed with my Vine? The year before last, when the Grapes were colouring, I unfortunately burnt some sulphur in the house to destroy mildew. The following morning the leaves were all curled, and ultimately dried up, and the fruit did not ripen. The following year the wood was very weak, and did not bear fruit; and this year, although there are a few bunches showing, the Vine altogether looks sickly and weak, and makes little wood. The Vine is about nine years old.—INQUIRER.

2225.—**Prickly Comfrey.**—I keep one horse and a pony, and should be glad to know how many plants of the above would supply them through the summer; also how far apart the roots should be planted.—DISPATCH.

2226.—**Books.**—Can any one inform me of the title, author, and publisher of practical books upon the undermentioned subjects, and for use in South Africa, viz.—1, agricultural chemistry; 2, diseases of vegetables and cereals, and their preventives; 3, cultivation of Maize, Tobacco, and Arrowroot?—S. V.

2227.—**Impregnating Flowers.**—Will any one explain to me how to impregnate the flowers of Calceolarias and Auriculas?—PRESS.

2228.—**Adiantum Farleyense.**—I should be much obliged for an account of the treatment and culture of this Fern, and the best way to grow it in a cool greenhouse in winter, or will it succeed better in a warm room at that time?—BLACKROCK.

POULTRY.

Feeding Hens when Sitting.—In reply to "Mabor," hens should always have free access to water; but neither food nor water should be given so that they can get it without coming off the nest; they should rather be encouraged to come off and run about, to stretch their legs, and air themselves and their nest every day. They should also always have free access to food, as you never can tell when they are coming off. A friend of mine used to lift his hens off the nest every day, and shut them away from their nest for an hour, covering the eggs with a blanket; but I do not think this a good plan, as the hens generally resent being lifted off, and in the struggle some of the eggs are likely to suffer. I find grain and Maize the best food for hens while sitting, and not soft food.—W. T. D.

Fowls Laying from Home.—We have no run for poultry except a farmyard and other grounds not in our own occupation. What kind of fowl (say half-a-dozen and a cock) would be most likely to lay in their own house: that is, not lay their eggs here and there in sheds, barns, &c., to which we have not convenient access? Also, where or how could we get the suitable kind? and, speaking roughly, about what would be the cost per head? All this refers to hardy fowls which would lay well. The house for them is roomy.—T. T. EWING.

Disease in Fowls.—Are your fowls kept on a run? If so, the run being stale would affect the fowls in the way you mention; or perhaps you have been giving them too much soft food and not enough solid. Cut the feathers off carefully with a pair of nail scissors, and give the chicks a dose of castor-oil, and feed them on solid food, such as good Barley or Maize; let them have as much liberty as possible, and if the run is stale, have it dug deeply all over.—W. T. D.

Eggs for Hatching.—Choose fair-sized eggs (the fresher the better), and look whether the air vessel at the round end of the egg is clear; this can be ascertained by holding the egg before a strong light; if the air vessel is clear the egg is productive. There is a saying that when the air vessel is at the top of the egg the chicken will prove to be a cock; when at the side, a hen; but this I do not believe.—G. W.

—— There is really no reliable means of telling whether an egg is fertile or not until it has been sat upon for four or five days. It should then be held up to the light, and if opaque, then it is fertile; but if transparent it is useless for sitting purposes, but may be used for cooking, as it will not have been injured in the least by the hen sitting on it for a few days.

Eggs not being Fertile.—I have six hens and one cock: two of the hens and cock are eleven months old, the rest are about two years and over; they are all in good health, and the cock very strong. I sat eggs from each hen, but they are not fertile. Will any one give me the reason?—A. P. K.

Prolific Fowls.—I have a hen which was hatched last March twelve months, and brought out a brood on Easter Sunday, and commenced laying again last Sunday. I think she may be called prolific, as I have kept fowls for the last nineteen years, and have never known one to lay again so soon. I do not know what breed she is, as I have no faith in what are called the fancy breeds.—THORBURN.

Nests for Sitting Hens.—Can any reader tell me what a nest ought to be composed of for a sitting hen? and which is the best way to make it?—H. E. B.

Poultry Breeding.—No matter what kind of hen may be used for hatching chickens, it does not affect the purity of any young chicks she may hatch.

Fowls with Diseased Legs.—We fancy the Brahma cock is either suffering from scaly legs—in which case the whole of the legs becomes covered with a hard scaly substance—or the hens peck the feathers off his legs. If the former, sulphur ointment well rubbed in will soon effect a cure; if the latter, the hens must be removed from the cock until the feathers are renewed

Purity in Crossing Breeds.—Will some experienced breeder kindly inform me the requisite time for removal of hens from present mate to the newly-intended cross?—W. N. G.

BEES.

A LONG spell of cold north-east winds and consequent drought has not been productive of good for the bees, as the insects are weak and suffer much from the cold. It is not probable that swarms will be early this year, as the stocks have been much emaciated by the severe winter, and, perhaps, far more by the very unfavourable state of the weather last year. We hear of lost stocks very frequently, and many small bee-keepers now find that in depending too much upon the natural food in the skeps they leant upon a broken reed. To this want of natural food, where not supplemented by feeding, is largely due the deficiency of early brood; and as a result, swarms will be later and weaker. A change to soft balmy winds and mild rains would be for the bees an immense boon, and little real work can be done until such change comes. Just now there is an ample store of food offered in the great bloom on the fruit trees, Apple trees especially; but the cold keen winds prevent that full action on the part of the insects that a more balmy air would encourage. One great danger is looming for the bees, and this is found in the multiplicity of wasps already. We have killed dozens of these pestilent insects during the past few weeks, and if every one represented a possible nest, then much good has been negatively performed. None the less large numbers are alive, and perhaps ere this depositing eggs in some secure place. Bee-keepers should keep a close watch for wasps now, and kill all they can find; if they do not, the progeny of these early birds may by-and-bye prove most destructive to their bee stocks. During hot dry weather keep water in shallow pans or troughs within reach of the bees, as just now, and always during hot weather, it is difficult otherwise for them to find the needful moisture.

A. D.

HINTS ON THE MANAGEMENT OF BEES.

MR. YATES, of Manchester, has sent us a catalogue of his beehives, &c., from which we extract the following hints:—

Aspect.—The situation of the hives as to aspect is not very material. A preference may be given to the south-east; but it is very important that they should stand in a place sheltered from the wind, and that they have an open space before them, so that the flight of the bees may not be impeded. If placed with the against a wall or fence, the stands should have a space of at least 3 ft. behind them, so that any operation the hives may require can be done from the back. The ground below, and immediately in front of the flight board, should be kept bare, so that bees returning heavily laden, if beaten down by a sudden storm, may not fall among long Grass, where they would get chilled and perish.

Bee Bench.—It is very desirable that hives have separate stands, and they would be better if placed not less than 3 yards or 4 yards apart, as any operation which may be required will be more easily performed when the bees only of one hive have to be contended with. The stocks will also escape several dangers they are liable to when a number of hives stand on the same bench. A post, with a flat square top, standing 9 in. to 12 in. out of the ground, with a board 15 in. to 18 in. square nailed on the top, will be all that is required. Let the board incline slightly to the front, that the water may run off the flight board instead of into the hive, and on this fixed table place the hive and board. It must be understood that the top of the stand just described is not intended to be the floor board of the hive: this must be a separate loose board, which must be lifted with the hive whenever required.

Covers for Hives.—It is necessary that straw hives should be well protected from the rain and sun and the more perfectly this is accomplished the greater the certainty of success; if the hives are wrapped with carpet or sacking, so as to prevent their being influenced by changes of temperature, so much the better, as they cannot be kept too dry and warm. Thatching with straw is an excellent plan; it may be done thus: Take a good-sized wisp of Wheat or Rye straw, and tie it very securely at the root end, then open and spread it evenly round the hive, the ear end hanging downwards; over this place a hoop of thick wire, which will hold the straw closely round the hive; and to secure it from high winds tie the wire hoop down to the stand, and trim the bottom of the straw neatly, a little lower than the floor-board, cutting it rather shorter over the entrance, which will then have quite a porch-like appearance. But perhaps the most durable and effective covering is made by placing a layer of Wheat or Rye straw, about ½ in. thick, between two sheets of poultry netting, and binding them neatly together; this placed round the hive will prove an excellent protection, and, with a galvanised milk-pail or an earthenware mug for a cover to keep off the rain, will prove everything which can be desired.

AQUARIA.

STICKLEBACKS IN AQUARIA.

ALTHOUGH numerous articles on aquaria have appeared in GARDENING ILLUSTRATED, I have not seen one in favour of sticklebacks; all that is said about them is that you had better keep clear of them in an aquarium. Now, I think them most interesting little fish—far more so than gold fish; and I think I cannot better undertake their defence than by giving an account of some kept by us. In the middle of our rockery nestled a tiny pond, about 3 ft. by 2½ ft., and about 15 in. deep. The rockery was carried down into the water at the back, and Creeping Jenny and Forget-me-not, planted in the crevices, grew down and floated on the water, the yellow and blue flowers looking very pretty. In the pond resided an eel, two or three leeches, shrimps, butterfish, little bright beetles which danced in the sun on the water, large flat beetles—beetles that come up for and carry down with them bubbles of air on the hind part of their body; red water spiders, water tigers, and last, not least, two male and ten female sticklebacks. About the middle of May, 1876, one of the male sticklebacks began to show signs of nesting by closely examining the whole pond—at which time his throat was a splendid crimson, and his eyes sparkled, and were the most lovely emerald green. Having settled on a spot, he began to bring pieces of weed, which he bit off the plants (Water Crowfoot), and buried the end, by bringing pieces of sand. At this time he was much annoyed by some spiders, who would persist in continually swimming about his nest. To get rid of them, he swallowed them, swam to a distance, and ejected them out of his mouth. The nest took four or five days to complete, and presented the appearance of an exquisitely-formed miniature bird's nest, so small that the top of the little finger would have covered it. It is said that he selects a lady fish, and drives her to the nest; if she approves of it she deposits her eggs there but we did not see this part of the performance. After the eggs were laid, he was sole guardian, and kept everybody at a distance; and as the other male fish had occupied the other corner of the pond, the rest had rather a hard time of it. In about ten or twelve days the nest was full of young fry, but so small as only to be perceptible on looking very closely. The fish hovered over and around them, and if any went out of bounds he brought them back in his mouth. He guarded them for about three weeks, when they became dispersed, and I think most of them were eaten by the other fish. If any one should take to keeping sticklebacks, be careful not to have too many males, as they fight desperately. Their mode of attack is to swim slowly under their antagonist, erect their spines, and rush violently backward, ripping him up. Our sticklebacks would, if you stirred the sand with a stick, range themselves round to seize the worms; and it was rather strange, if you put a finger in the water, to see them swim boldly up to it to see if there was any food. We fed ours on small worms and morsels of raw meat dried in the sun. PISCES.

White Matter in Aquarium.—Can any readers inform me what is the cause of the white film that forms on the gold fish in aquariums? We find that, however free they are at first, when they have been in for a week or so it begins to form, until it envelopes the whole fish, and then turns black. The fish grow weak, and at last die. Is there any remedy when it has once commenced?—UNA.

Gravel for Aquarium.—Should the top of an aquarium be covered in, or left open? Would fine gravel do for the bottom instead of shingle? and should the plants be put in the shingle or in pots?—MICK., *Cork*.

Caddis Worms.—I have a quantity of these interesting little creatures, newly collected, in my aquarium; and as I would like to watch their existence till the flies develop, I would feel obliged if some zoological reader would inform me what to feed them with, and give me any general information that may be useful.—W. C.

Water for Aquarium.—Would any one tell me if ordinary drinking water would do for an aquarium, and how often it should be changed?—J. T. M.

Gold Fish.—Has gas an injurious effect on a globe of gold fish in a small room? Also, is it necessary to feed the fish, or is water weed placed in the globe sufficient? PISCATOR.

Fish in Aquarium.—I have a small aquarium, 18 in. by 12 in. standing in a verandah out-of-doors with a fountain, which is playing for about two hours every day. I cannot get the fish to do at all; they seem very mopish, and are attacked with mildew. Can any one recommend a cure?—S. F.

Stocking an Aquarium.—Would your correspondent "W. B.," who gives such a clear and good explanation of "stocking an aquarium," in GARDENING of April 17, 1880, be so kind as to say whether sea or river shingle should be used, supposing each to be equally well washed; also, whether the water in bell-glass would require changing at intervals, and whether it would be necessary to cover glass to keep dust from the water?—T. K.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 3s to 6s; Azalea, 6s to 12s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 3s to 6s; Lily of the Valley, 6s to 18s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus, 4s to 9s; Pelargoniums (zonal), 3s to 6s.; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s; Violets (Neapolitan), 4s to 5s; Violets (French), 1s 6d to 4s 0d. —*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Camellias, 1s to 4s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 6s; Roses (forced), 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 3s to 6s.

Plants in Pots.—*Per doz.*—Arum Lilies, 6s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Cyclamen, 6s to 18s; Daphne indica, 12s to 24s; Deutzia gracilis, 9s to 18s; Dielytra, 9s to 12s; Dracæna (green-leaved kinds), 12s to 30s; Dracæna 18s to 60s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 12s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Azaleas, 10s to 20s; Maiden-hair Ferns (large), 4s to 7s; Cyclamen (large), 5s to 10s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 3s 6d to 7s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 6d.

Vegetables.—*Per 100.*—Asparagus, 1s 6d to 4s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips (outdoor), 3s to 4s; Radishes, 1s 6d to 3s; Herbs, 2d to 6d. *Per doz punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 5d to 9d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb, forced (per dozen bundles), 3s to 6s Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

NEW AND BEAUTIFUL

COLEUS,

OFFERED BY

James Carter & Co.

The Collection comprises the most beautiful and distinct varieties yet introduced, and includes a number of kinds raised by ourselves and now offered for the first time :—

	Each—s.	d.
Ami Constance	2	6
Alice	2	6
Allen Chandler	3	6
Baronne de Sparre	2	6
Canary Bird	3	6
Comtesse Agnado	2	6
Claire de Chandeneux	2	6
Comtesse de Seger	3	6
Dr. Moody	2	6
Gloire de Monceau	3	6
M. Ch. Joly	3	6
M. Ch. Avril	3	6
M. Camille Bernardin	2	6
M. Camille Paris	3	6
Mrs. Edwin Beer	3	6
M. Ed. Pynaert	2	6
M. F. Ouvre	2	6
M. F. Herincq	3	6
M. H. Jamain	2	6
M. L. Richard	2	6
M. M. Vilmorin	2	6
Madame Prilleux	3	6
Mrs. Sharman	3	6
M. Grakchef	2	6
Madlle. Lucie Thomas	2	6
M. Laforcade	3	6
M. Puteaux Chaimbault	2	6
M. A. Carriere	3	6
Miss Florence	2	6
Master Wilmot	2	6
President Hardy	2	6
Pictus Salicifolius	3	6
Souvenir de A. Guenot	2	6
Sir Sydney Dacres	2	6
Trissy Appleford	2	6

PRICE, the complete collection of 35 varieties, 90s.

THE QUEEN'S SEEDSMEN,

High Holborn, London.

BEDDING VIOLAS for the MILLION.—The hardiest, most effective, and longest blooming of all bedding plants. If properly treated will flower continuously from April till October, and they require no protection during winter. Autumn-struck plants in fine condition for present planting can now be had, FREE BY POST, with descriptive list and cultural directions—100, in 12 fine named varieties for 16s. ; 50, in 8 sorts, for 10s. ; 25, in 6 sorts for 6s.; 12, in 4 sorts, for 4s.—DICKSONS & CO., Nurserymen, Seedsmen, and Florists, 1, Waterloo Place, Edinburgh. Established 1770.

COLEUS.—Twenty new varieties, all distinct in well-rooted cuttings, for 4s. post free; ten for 2s. 2d.—C. SHAW, Florist, 72, Darlington Street, Wolverhampton.

STRONG-ROOTED Cuttings Alternanthera amœna, 6s. per 100. New Coleus—Garnet Fascination, G. Bunyard, Exquisite, Kentish Fire, Surprise, Beauty, Lord Falmouth multicolor, pictus, and two others, 2s. 6d. the doz. Sensitive plants, very amusing, 6d. each. Cyclamen, 1s. 6d. per doz. Harrison's Musk, 10d. per doz. Dwarf Ageratum, never exceeds 6 in. in height, 1s. 6d. per doz.—ROBT W. BEEDELL, The Nurseries, Wallington, Surrey.

T. FLETCHER & SON can supply the following in sample dozens, free by post :—Verbenas (purple, white, crimson, and pink), 1s. 2d. per dozen—see separate advertisement. Fuchsias, in twelve choicest exhibition varieties, at 1s. 6d. per dozen. Chrysanthemums, in twelve choice varieties, 2s. per dozen. Maréchal MacMahon Geraniums, at 2s. per dozen; silver tricolor, Glen Eyre, Beauty, Italia Unita, &c., 2s. per dozen. Heliotropes, 1s. 6d. per dozen. The following are package free :—Calceolarias Golden Gem and aurea floribunda, 8s. per 100. Bedding Geraniums (scarlet, pink, rose, &c.), 8s. per 100; silver edge, 9s per 100. Verbenas (purple, white, crimson, pink), 6s. per 100, 50s. per 1000. Terms cash with order.—Florists, &c., Chesterfield.

VERBENAS! VERBENAS!!—Strong, healthy, well-rooted Cuttings, free from disease, guaranteed to give satisfaction. At 6s. per 100, 50s. per 1000, of purple, white crimson, rose, and pink. Package free. Cash with orders.—T. FLETCHER & SON, Florists, &c., Chesterfield.

CHRYSANTHEMUMS.—Good strong rooted cuttings, post free; Large-flowered, Japanese, incurved, reflexed, and Pompone. Very choice varieties, with names, per doz., 4s. ; good standard sorts, per doz., 2s. 6d. ; good mixed, per doz., 1s. 6d. ; per 100, 10s. 6d.—DANIELS BROS., Town Close Nurseries, Norwich.

DICKSONS & Co., Nurserymen, &c., 1, Waterloo Place, Edinburgh, are now sending out their beautiful new Saxifrage Wallacei, which is just coming into bloom. It will stand in the open border during the severest winter, without protection, and bears the greatest profusion of pure-white flowers; 1st. class certificates, London and Edinburgh. Also the new double-flowered Matricaria inodora (figured in the *Gardeners' Chronicle* of 13th December, 1879). It is as hardy as the above; blooms from July till October, the flowers being pure white, and equal in quality to those of a fine Pompone Chrysanthemum. Engraving sent with three plants each of the above 1s. 6d. ; three for 3s. 6d. ; six for 6s. ; all free by post. Surplus stock of finest varieties of early and late Phloxes to be sold cheap. Prices and Descriptive Catalogue on application.

MADAME THIBAUT.—This is the best pink Geranium extant; strong plants, 16s. per 100. ditto market specimens in 4½ in. pots, 4s. per doz.; scarlet Geraniums, Vesuvius and Wonderful, strong plants, 16s. per 100. do. market specimens in 4½ in. pots, 4s. per doz.—GEORGE POULTON, Florist, Angel Road, Edmonton, London.

CATALOGUES, free on application, of splendid new Double and Zonale Geraniums, new Fuchsias and Coleus, thirteen of the choicest Lobelias, including the new Yellow, Heliotropes and Violas, a rare collection of Chrysanthemums (large-flowered Japanese Anemone-floweerd, and Pompone), Ageratums, Calceolarias, and Double Petunias, Dahlias, and a good variety of plants for carpet bedding ; also Cucumber plants.—GEORGE GUMMOW, 114, Loughborough Road, Brixton, S.W.

COLEUS.—From our splendid collection, in well-rooted cuttings, with names; very choice. Per doz., 3s. 6d. ; good showy sorts, per doz., 2s. ; mixed, per doz., 1s. 6d. ; per 100, 10s. 6d.—DANIELS BROS., Town Close Nurseries, Norwich.

CYCLAMENS.—Pot now for winter flowering. Strong healthy seedlings, in distinct, bright, and varied colours, 1s. 6d. per doz., 10s. per 100; choice mixed Anemone, 7d. and 1s. per packet, all post free.—J. CORNHILL, Byfleet, Weybridge Station, Surrey.

FUCHSIAS.—Well-rooted healthy cuttings, with names. New varieties of 1879, per doz., 6s. ; choice exhibition varieties, single and double, per doz., 4s. ; good standard sorts, per doz., 2s. 6d.—DANIELS BROS., Town Close Nurseries, Norwich

NEW COLEUS.—J. WALLACE has the finest collection in the world, including Glow, Distinction, Stella Harlequin, Surprise, Butterfly, Clown, Exquisite, Fascination. Pictus, Lord Falmouth, Garnet, Novelty, Wizard, &c., twelve selected, 2s. ; Wallace's prize Fuchsias and Chrysanthemums, 2s. per dozen ; Harrison's Musk, 1s. per dozen, post free. Cash with order. List of new Crotons, Dracænas, stove plants, &c., post free on application.—Pellatt Road, East Dulwich, S.E.

SPECIAL OFFER of BEDDING PLANTS.—J. WALLACE has pleasure in supplying the following in good plants : Mimulus, the finest varieties, 2s. per dozen ; Heliotrope, 2s. ; Iresine, 1s. 6d. ; Ageratum and Lobelia, 1s. per dozen ; Golden Pyrethrum, 2s. per 100 ; Dahlias, all the best, 3s. per dozen ; Bronze Geraniums, 2s. 6d. per doz. All post free ; cash with order.—Pellatt Road, East Dulwich, S.E.

SCRYMGEUR'S GIANT BRUSSELS SPROUTS, Green Curled Savoy, and Nonpareil Cabbage, 1s. 3d. 100, post free. Strong, healthy, spring-sown plants from open ground, much cheaper ; large quantities on rail.—Apply, EDWARD LEIGH, Norcote, Guildford.

CABBAGE PLANTS, autumn-sown, strong. Early Enfield, York, and Sugarloaf, 5s. 6d. 1000, 50s. 10,000 ; Robinson's Drumhead, 3s. 6d. 1000, 30s. 10,000 on rail, cash with order.—Apply, Mr. EDWARD LEIGH, Norcote Farm, near Guildford.

HARRISON'S GIANT MUSK.—Well rooted, healthy young plants of this superb variety, post free, 1s 6d. per dozen.—DANIELS BROS., Town Close Nurseries, Norwich.

MIMULUS DUPLEX and others (strong), 2s. doz. ; Stocks (large plants), 3 varieties, 2s. 6d. per 100 ; Golden Feather (strong), 2s. per doz. ; seedling ditto, 2s. 100 ; Lobelias (Blue and Rose), 2s. 100 ; Phlox Drummondi, 12 colours separate, 2s. 6d. 100.—WM. HOLDEN & CO., Florists, Westhoughton, Bolton.

BLOOMS of Fine BEDDING VIOLAS and other Spring Flowers will be sent on receipt of nine postage stamps.—DICKSONS & CO., 1, Waterloo Place, Edinburgh.

TELEGRAPH CUCUMBER SEED, warranted.—Eighteen seeds, 1s. ; seven seeds, 6d. Primula sinensis fimbriata, 2s. 6d. and 1s. 6d. per packet, or thirty-six seeds for 6d. ; Cineraria, 1s. per packet, or thirty-six seeds for 6d. ; Cyclamen persicum, twenty seeds for 7d. ; Pansy (fancy-striped), 4d. per packet ; Balsam (double Camellia-flowed), twenty-four seeds for 4d. —this is something special ; Polyanthus (gold-laced), 3d. per packet ; Russian Violet, 3d. per packet ; Phlox Drummondi grandiflora, fifty seeds for 3d.—finest Phlox in cultivation ; post free. Any other new and choice seeds at low prices. Catalogues free.—ROBT. W. BEEDELL, The Nurseries, Wallington, Surrey.

CHOICE FLOWER SEEDS of unsurpassable quality. Amateurs' packets, 6d. and 1s. each. Primula, finest fringed (includes Williams's coccinea, and all the finest light and bright varieties) ; Cyclamen (includes giganteum), Begonia, Calceolaria, Carnation and Picotee, Cineraria, Alpine Auricula, Show and Fancy Pansy (extra choice), Polyanthus, Petunia (single and double), &c. &c.—TODD & CO., Seedsmen, 7, Maitland Street, Edinburgh.

J. C. STEVENS, HORTICULTURAL, SCIENTIFIC, and NATURAL HISTORY SALE ROOMS, 38, King Street, Covent Garden, London. Established 1760. Sales by Auction nearly every day. Catalogues on application or post free.

ORCHID BASKETS (great reduction in).—Teakwood Rods, rounded edges, made with strong copper or galvanised wire. Every kind made for growing Orchids at 50 per cent. less than usually charged. Send for List of Prices, for 20s. Sample Order, carriage free. Teak rods supplied, prepared, and drilled ready for making up.—ALFRED GRANT & Co., Steam Works, 39½, Leather Lane, London, E.C.

PAINT.—Large quantities for Sale, specially prepared for Horticultural Buildings, Greenhouses, &c., 2½d. per lb., all colours. Improved Zinc White Paint, 4½d. per lb. Cash. —A. LEETE & Co., Paint Manufacturers, 129, London Road, South wark, S.E.

TOBACCO CLOTH AND PAPER for Fumigating. Buy of the maker direct. Write for samples. Best in the market. Cloth 8d. per lb., 28 lb. 18s., 1 cwt., 65s. Paper 7d. per lb., 28 lb. 16s., 1 cwt. 56s.—J. DENYN, 73, Rendlesham Road, Clapton, London.

WOLFF'S INDELIBLE GARDEN PENCILS, Black, Red, and Blue.—The writing will withstand the action of air, rain, &c. Price 3d. each (with Point Protector). Sample on receipt of four stamps. Of all Seedsmen, and of the Manufacturers, E. WOLFF & SON, 55, Great Queen St., London, W.C.

PLANT LIFE.—The Social Science Greenhouse Warmer, for small and large spaces, for Household Rooms, Offices, Studios, Churches, &c. Can be regulated to any temperature ; failure out of question. Burns from 12 to 24 hours without attention ; costs half less than any other heating power. Prices, 6s. 9d., 8s. 9d., 10s. 6d., 15s. 6d., 18s. 6d , 21s., 25s. 6d., 28s. 6d., 31s. 6d. Send area of space to be warmed.—T. G. POTTER, Stella Lamp Depôt and Court of Household Inventions, 17, Oxford Street, W. Catalogues free.

HEAT! HEAT!! HEAT!!!—W. PRANGNELL'S New Stoves, the Invincible and Eureka, will keep out 20 deg. of frost from 12 ft. to 18 ft. greenhouses ; burning twenty to twenty-four hours at a cost of threepence ; requiring no attention ; can be fixed in two hours. Price £2 2s. to £3. 3s.—Manufactory—81, Southampton Street, Camberwell, S.E.

GARDEN Stakes, Labels, Virgin Cork, Mats, Raffia, &c. None cheaper.—WATSON & SCULL, 90, Lower Thames Street, London, E.C.

THE AMATEUR'S GUINEA CRATE of GARDEN POTS contains thirteen dozen POTS, SAUCERS, and SEED PANS, from 3 in. to 8 in. in diameter, including crate and carriage free to any goods station in England or Wales. Cash with order. N.B.—Two-guinea crates will contain double value and pots up to 10 in. in diameter.—JOHN MATTHEWS, Royal Pot teries, Weston-super-Mare.

LARGE CONCH SHELLS, for Ornamenting Gardens. The weather improves them. A cask containing between 45 and 50 sent by luggage train, 20s. Just imported.—WM. CROSS, Importer of Beasts, Birds, and Curiosities, Earle Street, Liverpool.

THE NEW GARDEN HOSE.—Made upon the principle of the New Fire Hose used by Capt. Shaw, C.B., Chief Officer of the London Fire Brigade. There are twelve reasons why it is better than any rubber or fabric hose, and not the least important ones are—1st, it is much cheaper ; 2nd, it is by far more durable.—MERRYWEATHER & SONS, Manufacturers, 63, Long Acre, London. Works—Greenwich. Private customers supplied at trade list prices ; sample free.

GARDEN REQUISITES.—Cocoa-nut Fibre Refuse, 3d. per bushel, 100 for 20s., truck (loose), 30s. Light Brown Fibrous Peat—5s. 6d. per sack, 5 sacks 25s., 12 for 45s., or 36s. per ton. Black Fibrous Peat—5s. per sack, 5 sacks 22s., 12 for 40s., or 34s. per ton ; sacks 4d. each Coarse Silver Sand—1s 9d. per bushel, 15s. half-ton, 26s. per ton ; in 1 cwt. bags, 4d. each. Yellow Fibrous Loam, Peat Mould, and Leaf Mould—1s. per bushel. Sphagnum Moss—8s. 6d. per sack. Manures, Garden Sticks, Virgin Cork, Tobacco Cloth and Paper, Russian Mats, &c Write for free Price List.—H. G. SMYTH 10, Castle St., Endell St. Long Acre. W.C.

COCOA-NUT FIBRE REFUSE, as supplied to all the Royal Gardens of Europe. Useful at all seasons. Invaluable for Potting, Forcing, Ferneries, Strawberries, Bedding-out Plants, &c. Destroys all slugs and insects. Bags (about 4 bushels, per bag, 1s. ; 15 bags, 12s. ; 30 bags, 20s. (all bags included). Van load at works, 4s. ; ditto, delivered within 5 miles, 10s. ; Truck load (about 250 bushels), free on rail, 25s. Terms cash with order.—CHUBB, ROUND & Co., Fibre Works, West Ferry, Millwall, London, E.

COCOA-NUT FIBRE REFUSE.—Useful at all seasons. Largest makers. 1s. per bag, 30 bags £1 (bags included), truck 25s., free to rail. P.O.O. to A. FOULON, Fibre Merchant, 32, St. Mary Axe, London, E.C.

GISHURST COMPOUND.—Used by many of the leading gardeners since 1859 against red spider, mildew, thrips, green fly, and other blight, in solutions of from 1 to 2 oz. to the gallon of soft water, and of from 4 to 16 oz. as a winter dressing for Vines and fruit trees. Has outlived many preparations intended to supersede it.—Sold retail by seedsmen, in boxes 1s., 3s., and 10s. 6d. Wholesale by Price's Patent Candle Company (Limited).

AMERICAN BLIGHT ON APPLE TREES CURED by rubbing a wet hard painter's brush on Gishurst Compound and working the lather into the infected part.

RIMMEL'S NEW TRANSPARENT COAL TAR SOAP, combining the purifying action of coal tar with the refined and emollient qualities of transparent soap. It does not colour the skin as ordinary coal tar soap is liable to do, and its perfume is much more agreeable. Price 6d. per cake. Sold by all the trade, and manufactured only by E. RIMMEL, Perfumer to H.R.H. the Princess of Wales, 96, Strand ; 128, Regent Street ; and 24, Cornhill, London ; 76, King's Road, Brighton.

VIRGIN CORK FOR FERNERIES AND CONSERVATORIES.—The Cheapest and Best house in London.—GEORGE LOCKYER & Co., 13, High St., Bloomsbury, W.C.

FOR SALE, two new unglazed lean-to Greenhouses, tenant's fixtures, 12 ft. by 5 ft., price £4, delivered to any railway station in England on receipt of P.O.O.—Apply to A. P. JOHNSON, Joiner, Wilmington, Hull.

Protect your Fruit Trees, &c.

TANNED GARDEN NETTING, yard 1 wide 1d., 2 yards wide 2d., 3 yards wide 3d., 4 yards wide 4d. per yard. SCRIM, TIFFANY, PATENT SHADING, &c. Sample Book of the above, post free, two stamps. Second-hand BUNTING (all wool), 6d. per square yard. Archangel and Dunnage MATS, &c. Illustrated Catalogues of all their manufactures on application.—JOHN EDDINGTON & Co. (established 1805), Marquee, Tent, Flag, and Rick-cloth Makers to the Royal Family, 48, Long Lane, West Smithfield, London, E.C.

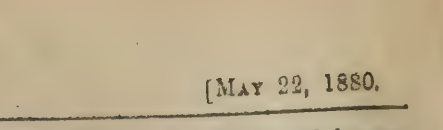
By Royal Letters Patent.

GAS CONSERVATORY BOILER.—Reflector Gas Cooking Stove, 10s. 6d. to £10.

EXCELSIOR GAS BATH, £5 10s.

Testimonials on application. Enclose stamp.—G. SHREWSBURY, 59, Old Bailey, and 98, Barrington Road, East Brixton.

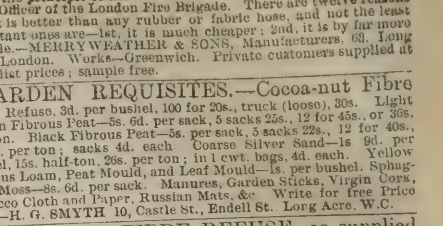
London-made Galvanized Wire Netting



PEA GUARDS AND ROSE STAKES.

Price Lists on application to

A. HANCOCK, 406, EUSTON ROAD, LONDON.



GYDE'S IMPERIAL FERTILISER.

ESTABLISHED 1839.

Forty years of increasing success.

Perfection in Artificial Manures for Flowers, Fruits, Vines, and Vegetables.

Testimonials from all parts of the Kingdom justify us in stating that our Manures and Plant Foods are perfect.

To be obtained of principal Florists and Seedsmen.

For the convenience of consumers, our Manure is packed in bags containing 1 cwt., 16s. ; ½ cwt., 9s. 6d. ; ¼ cwt., 5s. ; 7 lb., 3s. 6d. ; 3½ lb., 2s. 4d. ; Tin, 1s. Directions for use sent with each Order.

CAUTION.—Each bag bears a fac-simile of the Prize Medal as a guarantee against spurious imitations.

Prepared only by STROUD CHEMICAL MANURE COMPANY Stroud, Gloucestershire,

W. TRINDER, Manager.

TOBACCO FIBRE INSECTICIDE.

ALL who have a Greenhouse, and love to see their plants clean and healthy, should fumigate with DARLINGTON BROTHERS' TOBACCO FIBRE. Contains more Nicotine than any other insecticide sold ; will not lose its strength or go mouldy by keeping ; will not flare in burning ; perfectly safe, and highly effective ; purer and better than the best Tobacco Paper or cloth ; simple to use ; no apparatus ; common garden pot only required ; 40 per cent. saved by using this article.

Prices, 6 lb., 5s. 14 lb. 11s. ; 28 lbs., 21s. All parcels carriage paid to London. Special quotations for larger quantities.

BEST ROLL TOBACCO PAPER AND CLOTH, same prices as above. Best paper and cloth made ; *vide* Testimonials, free on application.

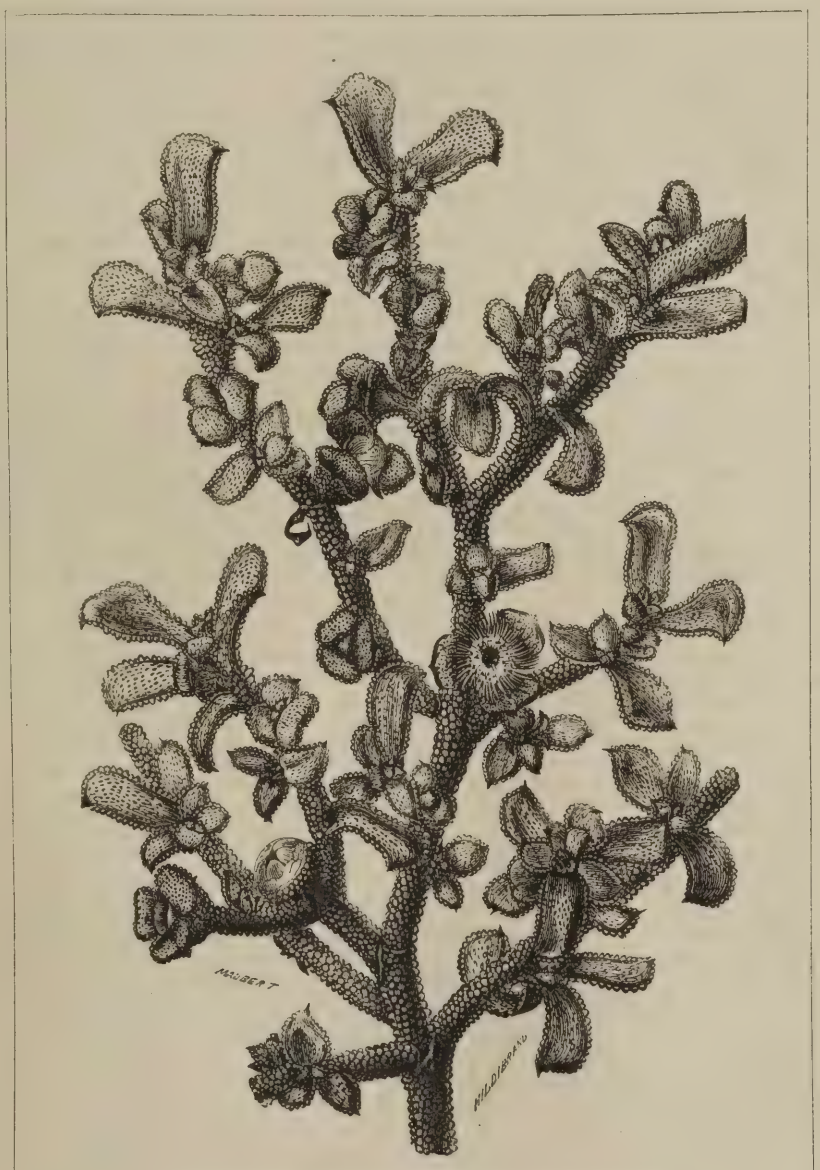
Manufactured by DARLINGTON BROS., Frederick Street, Chatham. Cheques crossed "London and Provincial Bank." P.O.O., Darlington Bros., Chatham.

GARDENING ILLUSTRATED.

VOL. II.—No. 64 *SATURDAY, MAY 29, 1880.* PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

ICE-PLANTS.

SUCH a long-winded name as Mesembryanthemum for an annual almost alarms one, and that, too, belonging to our common Ice-plant (M. crystallinum), of which the annexed is a representation, a plant grown in most large gardens for garnishing purposes; it is also sometimes used as a pot plant, but it is most effective when planted out on rockwork, or better still, on some old terrace wall, if such exists, allowing it to fall over its face. It will, however, grow in any good soil in a sunny situation, and it might be used as a band to a sunny border. It will grow from 3 ft. to 4 ft. in a season, and on warm days has a cool and refreshing look. Its flowers are unimportant compared with the crystal-bespangled stems and foliage; and the richer the ground the greater the crystal development. Seeds of it should be sown in heat in March, but if sown now and planted from 6 in. to 8 in. apart, fairly good results may be had in late summer, or plants of it ready to plant out at once may be had at most nurseries at a cheap rate. There are two varieties of it—one with red, and the other with white flowers. This, it must be remembered, is not the Ice-plant of cottage windows: that is a perennial named M. cordifolium, the variegated form of which is largely used in carpet gardening. M. pomeridianum is a strong-growing species, with broad spathulate foliage and large purple and rose-coloured flowers. As its specific name indicates, it flowers in the afternoon. It is not so common a kind as the last, but it well deserves a place on a south border. M. tricolor is perhaps the most showy of the annual Mesembryanthemums; it is a neat plant, with cylindrical foliage, and is not a creeper; it grows 6 in. or 8 in. wide and 4 in. or 6 in. in height; of its flowers, which are abundant, some are purple and the others rose, the result being a good contrast; this species should be sown in a sandy soil in the open garden about the end of April, or even now; it dislikes transplantation, and it lasts longer in the ground than in a pot. M. pinnatifidum is a pretty little plant which has the habit of M. crystallinum, but is not so rampant a grower; the foliage is semi-pinnate, and the flowers small and red in colour. M. anatomicum is another kind, curious rather than showy; it is not generally grown as an annual, but it does best treated in that way; it creeps on the ground, and seems to get rid of its epidermis as quickly as possible, a circumstance which gives it the appearance of a skeleton. When grown in pots in windows Ice-plants require light, rich, sandy soil and a sunny position.



ICE-PLANT (MESEMBRYANTHEMUM CRYSTALLINUM).

FAIRY ROSES.

These are grown by thousands for the London markets. They are raised from the young tops of plants inserted in sharp sandy soil in May and June. They are placed in a warm close house or pit until rooted, when they are potted on in good sandy loam, until they are in 5-in. pots. They are then grown in airy houses and by the following spring they are loaded with buds and rosy-coloured blossoms, the dense masses of green leaves hiding the pots. Such plants as these find a ready sale in markets, great numbers of them being cut up and used in bouquets, the small green leaves and buds being very effective among light-coloured flowers. During the time in which the plants are coming into bloom they are arranged on stages, receive abundance of water, and are frequently fumigated to keep down insects. Many thousands of them can be placed in a comparatively small house, and when coming into bloom they present a most striking feature. In the centre of each pot is placed a stake, to which to tie the leading shoots and thus induce the plants to assume a pyramidal, though by no means a formal, shape. They grow about 9 in. high and about as much through at the

base, and they form ornamental objects for some time, even in a sitting-room.

Insects on Roses.—Those intending to exhibit Roses will require to pay every attention at this season, so as to protect the buds from the depredations of the various insects. May bugs are very destructive at this season of the year, the evening being the best time to destroy them ; aphides should be thoroughly cleared off by means of the garden engine, and by carefully washing the trees the fly can be dispersed. It is not safe to apply any insecticide for the destruction of fly at this season, as the foliage and flowers are too far advanced, and if Tobacco water or any other deterrent be used and not efficiently washed off with clean water, it will often stain and spoil the appearance of the foliage. Tea Roses will be found to be attacked by mildew, owing to the cold and changeable weather. The best way to prevent such a mishap is to sulphur them carefully, and then thoroughly to syringe the trees after three days. The caterpillar and Rose maggot should be picked off every day. The maggot will be found curled up in the foliage and in the centre of the buds, and by steadily examining the Roses every day these pests may be well kept under. Take off all lateral buds, leaving nothing but the centre flower, so as to throw the strength into the single bud ; by so doing the Rose is much larger and better formed. The buds selected for exhibition should be carefully staked and tied, so as to protect them from stormy weather, taking care not to injure the foliage in tying or supporting the young growth. Water the plants occasionally with a mixture of cow manure, sheep-droppings and soot water, mixing the whole in a large tub, which will be found to improve the growth as well as the colour and size of the flowers. Such Tea Roses as Maréchal Niel, &c., require a paper shade where much exposed to the sun's rays, in order to keep the outside petals from being discoloured ; by the use of paper shades Roses may be kept back a day or so, a delay which will be of great service to those who have but a limited stock to cut from. Roses when cut should be placed in tubes in water mixed with a small quantity of Condy's Fluid, to prevent them opening too quickly. Roses for exhibition should not be cut in full bloom, but should be about half expanded, the heat of the day very frequently being prejudicial to them.—G.

The Rose Maggot.—This maggot is very annoying to the Rose grower, boring into the best buds, and destroying many a cherished hope of fine flowers. There seems to be no possibility of escape from it ; every year it makes its appearance, and if not destroyed in the spring as it comes to life, scarcely a perfect flower will be obtained, especially early in the season. At the time of pruning, every bit of the prunings, with the pips, if any remain, should be carefully gathered up and burnt. As soon as the shoots begin to push, and the leaves expand, the larvæ will make their appearance ; they may easily be detected by the web they spin, coiling themselves up in the young leaves. It is here they must be looked for with care and destroyed, going over the trees once a week, crushing them with the fingers ; for, if allowed to remain, as soon as the buds make their appearance they will spoil them. In confined beds and over-sheltered Rose gardens, this insect is much more prevalent and destructive than in the extensive open grounds. The more exposed situations appear to be uncongenial to this and other insects that infest the Rose.

Standard Roses in Pots.—Where there is a demand for cut Roses early in the spring, and these have to be brought forward in Vineries or other fruit houses, standard plants will generally be found the most useful shape, as, owing to their heads standing out in the full light, both flowers and foliage during short days come stronger than on dwarfs. They are also most suitable for conservatory decoration, as they can be placed in positions in borders amongst permanent plants, where their naked stems can be hidden, and thus be rendered more effective than small dwarf plants. Standard Roses may be kept in health for many years in 8-in. or 10-in. pots by annually shaking them out in autumn, shortening their roots a little, and re-potting them in clean pots of the same size. Good loam, well enriched with thoroughly decomposed manure, is the most suitable compost in which to pot them ; and if the loam be very adhesive, a liberal addition of road sand will be a great improvement.

FRUIT.

Treatment of Hardy Fruit Trees.—At this season, when all kinds of hardy fruit trees are growing luxuriantly, it is well to bear in mind that next year's crop depends in no small degree on the treatment that the trees receive this year ; therefore they must be kept clean and healthy to bring about successful results. One of the most important operations connected with fruit culture now demands attention, viz.—the pinching, stopping, and regulating of shoots. Summer pinching of the new growth, to induce fruitfulness, is much preferable to winter pruning, for nearly all kinds of fruit ; and, if done properly and at the right time, the best results may be anticipated. Frequently, for the sake of appearance, the shoots are pinched in too closely, and growth thereby is too much repressed ; sometimes they are allowed to run wild, and then removed wholesale—a proceeding which is ruinous to the commonest fruit : extremes either way should be avoided. Apples, Pears, Plums, some kinds of Apricots, and all kinds of Cherries except Morellos, bear their fruit on side shoots or projecting spurs, and therefore the new growths of these, as a rule, should be stopped at the fourth or fifth leaf ; if pinched in closer than this, the buds "close home" break into new growth in lieu of forming fruit-buds, which is the object desired. Let it be granted, that by leaving them there the spurs in time become long and far removed from the wall, then, to a certain extent, the wall becomes useless as a protector ; but it is an easy matter to remove annually at the winter dressing a few of the longest spurs, and so by degrees renew those on the entire tree. Of course, when stopping has been once done at the distance named, any supplementary growths of this season may be stopped at the first joint, and repeated as often as growth makes the operation necessary. If, as sometimes happens, new growths have been left too long without having been removed or stopped, do not remove them all at once, as that would give the trees a severe check ; but take off a few shoots at intervals of three days till all be removed. It is always advisable, however, to obviate this by stopping as growth progresses. Peaches and Nectarines that were not sufficiently disbudded should have their new growth pinched in rather closely—this, in their case, being preferable to disbudding at this late period. If not already done, the fruit should be thinned at once, and the same remark applies to other kinds of fruit that have set thickly, particularly to Pears. Water Strawberries in the absence of rain, as they soon suffer if they lack moisture at their present stage.—W. H.

Watering Strawberries.—In treating upon Strawberry culture, it is generally assumed that they are planted in strong, heavy land, as that is the best adapted to this fruit ; but the soil of many gardens is of a light sandy nature, not calculated for the satisfactory growth of Strawberries without especial attention, and which will need a plentiful supply of water ; as now, whilst the fruit is swelling, the energies of the plants are taxed to the utmost, and if deficient in moisture at the roots, the produce will not be satisfactory. It should always be remembered that in applying water, especially to a crop like this, one good soaking is much more effectual than several insufficient applications.

The Morello Cherry.—This Cherry seems to be less affected by frost than other kinds, and its comparative immunity in this respect doubtless arises from the pendant or drooping character of its branches. As a standard it is singularly handsome, and on that account deserves a higher place than is commonly assigned to it amongst decorative trees. But, beautiful and floriferous as it is in spring, it is even more ornamental during summer, when laden with its rich red crop of fruit ; the latter, owing to its tartness, is not so much sought for by birds as that of the sweet kinds. Morello Cherries generally realise good prices in the market, where they are usually sold in baskets containing a dozen pounds.—A.

VEGETABLES.

GROWING CABBAGE.

Cabbage will grow anywhere and under any conditions, but, like most other vegetables, it delights in a deep rich soil ; it is desirable, however, to have it in a somewhat firm condition where early produce is desired. In some places young Cabbages are frequently cut off by severe weather in winter, especially if planted in autumn in loose freshly-worked land. The remedy in such a case would be to make the ground somewhat firm before planting, or to have it prepared a month or so before, in order to give time to settle. Planting any kind of green crop on loose soft land in autumn encourages an early luxuriant growth, which is liable to suffer during a severe winter. Of course, where the land is never dug more than one spit deep, the objection does not apply with so much force ; but every cottage gardener ought to arrange his cultivating operations and his crops in such a manner as to enable him to dig the whole of his land at least 2 ft. deep every four years ; and he will find in the long run that this, instead of adding to the cost of working his land, will in reality cheapen production, if the improvement in the quality and quantity of the crops be taken into consideration. It scarcely requires any argument to prove that anything that opens up new sources of plant food almost free of cost must be a great boon to the cottager, and will eventually become an increasing source of profit to him.

Sow from the middle to the end of July, according to the earliness of the situation. If the weather be dry, which is frequently the case in July, have the ground thoroughly soaked with water twelve hours before sowing the seeds, and afterwards shaded by laying a mat over the bed. Rhubarb leaves or branches with the leaves adhering can be used, only they must be removed and the earth between the young plants loosened up as soon as they appear. The seeds should be sown thinly in drills about 8 in. apart, and the ground for the main crop should be prepared and made ready for planting by the first or second week in September.

Planting.—Many cultivators usually plant Cabbages after the Onion crop, I have done so for years ; and the only labour necessary is to hoe the ground up deeply, draw drills 2 in. or 3 in. deep and 20 in. apart, and plant in the drills 18 in. apart. This plan answers well where the ground has been deeply worked and made very rich for the Onion crop, but must not, of course, be taken as applicable to every situation and under all circumstances. The small plants that are left in the seed-bed may be pricked out thickly in some vacant corner till spring ; they will come in useful to fill up vacancies and to make another small plantation for succession to those planted in autumn. If it be considered desirable, another sowing may be made in March or April to plant out in any spare land for autumn use, but, unless the demand for Cabbages be considerable, this will hardly be necessary, as if the stems from which the early Cabbage have been cut be allowed to remain, and the leaves carefully trimmed off, each stem will produce three or four small hearts quite equal to those planted late in spring in quality, though not quite so large ; in fact, the second crop on good land is superior to the first. The old stems should be cleared off in time to have the land ridged up roughly in winter for Potatoes the following season, as that crop will be found a very good rotation ; and, as other crops of Greens will be ready by that time, the Cabbages may be dispensed with. Three of the best kinds for garden culture are Atkins's Matchless, Wheeler's Cocoa-nut, and Enfield Market.

Cutting Asparagus.—Asparagus should not be cut till the second year after planting, and then only sparingly. By allowing the plants to get well and firmly established before making a very free use of the knife, and with judicious after-treatment, they will produce excellent crops for many years ; and at no time cut too severely, but bear in mind that the more copious and healthy the foliage during the summer, the stronger will be the produce next spring. As the strength of the roots depends on the quan-

tity of foliage, there must be shoots enough left to sustain them healthy and vigorous, and to replace and store up for the following season sufficient matter for the healthy action of the plants. It is not advisable, however, to cut away the strong shoots and leave the smaller ones; quite the reverse. Allow some of the finest shoots to grow after the first fortnight or three weeks' cutting is over, removing any small spray that may appear; for a few strong shoots to each plant, properly exposed to light and air, will be more beneficial than any quantity of small ones. In cutting, a little of the soil is removed from the necks of the shoots with the Asparagus knife, which is then pushed down, carefully avoiding injuring the crowns or other shoots that may be pushing up. When the knife is at the base of the shoot, give it a slight twist towards—at the same time pressing it close to—the shoot; then draw it gently upwards, by which process the shoot is separated from the plant. The knife generally used in this operation has a rough or saw-like edge, set to cut only one way, and that by pushing down. It should always be kept sharp at the three or four first teeth from the point. For those that are fond of natural unbleached "Grass," any kind of knife will do, and in kindly growing weather the heads may even be broken off without a knife. Asparagus for market is generally blanched by the earthing-up system, which is done by covering the crowns with a few inches of light soil, generally taken from the space between the rows, by which process we obtain the white bleached or blanched shoots daily seen during the season in the London market. When this method is adopted, the shoots must be cut below the surface just as they appear. The cutting season should cease about the middle of June, and in no case should it be continued after the end of that month. When green Peas can be had Asparagus is less required; therefore, it is desirable to discontinue cutting after the 10th or 15th of June.

The Turnip Fly.—There is not a farmer or gardener in England who at the present is not dreading the attacks of that pest the Turnip fly. If they will only drill in a small quantity of peat charcoal along with Turnip and Mangold seed, they will find that the young plant rushes up with the broad leaf so quickly that the crop will be secured. If the drought becomes exceptioually severe, a sprinkling of this charcoal on the little plant will also save it from being eaten up. I have seen the effects of it during the past three years, and I think that your readers should know of it.—A. W. E.

Dandelions for Salads.—This somewhat resembles the Endives, and is one of the earliest and most wholesome additions to the salad bowl. Sow in May and June, in drills about 6 in. apart, and thin out the young plants to 4 in. apart in the rows. These will be ready for use the following spring.—J. Burrows.

Cats in Gardens.—An old friend of mine who was much pestered by cats told me with much glee of the success of a plan he had hit upon. His cure was to first catch his cat in a trap, and then not to kill but cure the sinner. This he did by subjecting him to the water cure, in the shape of a slow discharge of some two gallons of water, and then as soon as possible after the operation to open the door of the trap and let the prisoner go free. "If," said he, "you kill a cat, his successor will soon visit you; I never see the same cat twice." He found it better to educate than destroy.—R. G.

Ants.—Some time since I was troubled with ants in my garden. Spending an evening there in the midst of summer, my little girl accidentally dropped a piece of loaf sugar near their chief resort; in the morning I found it literally covered with the pests. Both sugar and ants were quickly destroyed, and I have not been troubled with one since.—T. W. Carwarding.

Hares and Rabbits Barking Fruit Trees, &c.—Lately I have been troubled with hares, &c., barking my young fruit trees, and tried a remedy which proved most effectual to prevent the mischief—and that was by mixing petroleum with fresh cow-dung, and with a brush painting all the stems and branches within their reach; one application was sufficient. Some of your readers may be glad to know it.—Wm. Fisher.

The Purslanes (Portulacas). — These supply some of the most brilliant colours among flowers, and when the sun shines fully on the plants, and the expanded flowers are open to the eye, the effect of a line or large patch of plants is very fine. Portulacas can be had in both single and double forms. Some prefer the former and some the latter, but both make effective border flowers. Of the single flowers, the best are aurantiaca, golden-buff in colour, some of the flowers having more yellow in them, but both forms very pretty; occulata, having a yellow centre with a purple ring round it, and a broad margin of white, very good and distinct; splendens, a variety well named, the colour

Single-flowered Purslane (Portulaca).

rich purplish-crimson (this is one of the very finest varieties); Thellusoni, orange-crimson, very fine; and Thorburni, bright yellow and very distinct. At some time or the other these single Portulacas showed a tendency to become double, and this having been followed up, a race of double varieties has resulted. These are all, more or less, double forms of the single varieties, and by dint of selection they now produce very large and full double flowers. The yellow and buff are double forms of aurantiaca, and, being flushed with red on the interior of the petals, are highly effective. Rosea plena, bright rose, is very handsome, and some of the flowers take on a depth of colour which makes it appear to be a double form of splendens. One

Double-flowered Purslane.

of the most beautiful varieties is caryophylloides; its flowers are fully double, and are marked with purplish-crimson on a blush ground, and broadly flaked with the same. The Sulphur is a double form of Thornburni. There are other colours, but the selection given is one of the most distinct, but all are good. These are well worth cultivating, but should be grown well. It is a common practice to starve Portulacas, as if they did best when in this poor condition. I hold the opinion that, like many other plants, Portulacas should be planted in good soil, in which they can thoroughly establish themselves, covering the surface of the ground with a dense coating of foliage, and then when the hot bright midsummer sun falls on the plants, hundreds of splendid flowers leap up responsive to its influence. Portulacas are most effective when they are not unduly crowded. Individual plants should have ample space in which to grow, as they quickly cover a good space of ground. The soil being made good, the surface should be covered with ½ in. or so of mortar rubbish, and over this some fine soil should be sprinkled. On this let the seed be sown thinly, and all in danger of being crowded removed as soon as large enough. The roots grow quickly through the grit to the rich soil below, and the plants, becoming thoroughly established, bloom on till autumn dims their lustre. A packet of seed of the large flowered P. grandiflora will yield a variety of fine brilliant colours, suitable for masses or edgings to beds or borders. The seed may be sown in the open ground from April to June.—A.

THE RANUNCULUS.

(Continued from p. 136.)

Subsequent Treatment.—The plants will make their appearance in a month or five weeks; after which it will be advantageous to press the soil closely around them with the hands, stopping up the holes made by worms, frost, and the protrusion of the leaves through the surface. A slight treading between the rows will give a compact surface, and make room for the top-dressing. This should consist of rich compost, chiefly of decomposed manure (free from wireworms). It should be added first as a protection from cold drying winds, and subsequently as a source of nourishment to the roots, carried down by the agency of rain. Night soil that has been exposed and pulverised may be used in the top-dressing, but it must be used with caution, as it is a powerful stimulant. The uncertainty of our climate and our liability to the recurrence of frosts in April, and even May, is undoubtedly an obstacle to the easy and certain success in the culture of this flower; but then the same observations apply with equal force to the Tulip, and other floral gems of the open garden. It is proper, then, as far as possible to guard against this evil, by having a quantity of flake hurdles at hand to cover at least the best beds. Short stakes should be driven in the ground to support the hurdles just above the foliage. Other means of shelter may be useful, but as the object is the security of a nearly hardy plant, a close protection would be injurious, as it would weaken and draw both foliage and blooms, and thus render the plants more subject to injuries from being delicately brought up. Should the grower from any circumstance have neglected to cover his beds, the first step to take on rising in the morning on which the frost occurs is to put on the hurdles, and then cloths or mats, and not remove the covers until the plants and ground are thawed; after which the light should be admitted gradually, by propping up the hurdles on the north side, and the direct sunshine excluded some time after all remains of frost have disappeared. If large worms exist in the beds, they should be collected by hand at night, or destroyed by lime water, used in a clear state. The ascent and descent of worms is injurious to all choice plants, and especially to the Ranunculus, which, from its shallowness in the soil, is the more exposed to harm from such disturbances.

Watering.—Genial showers in April and May are essential to a vigorous and healthy growth. The Ranunculus delights in a moist soil, and if there be a deficiency of rain in May, water must be plentifully supplied, just at the time the flower buds are appearing. This is a critical period; and for lack of moisture many plants fail to bloom, and send up only an abortive flower stem. Water from a pond or brook is better than from a well; if such cannot be obtained, fill a large vessel with water from a pump and expose it to the sun and air before use. It should be applied (morning or evening, according to the state of the temperature) between the rows, from a tube pot, and not over the foliage, except in cloudy and showery weather. It may appear an anomalous direction to water in wet weather, but advantage should be taken of a shower falling to give a generous overhead watering, as the plants are then naturally in a better state to receive moisture than in dry weather, when their pores are contracted. As a general observation, it is better to water copiously three times a week than to administer a

small quantity every morning and evening. To obtain fine blooms for exhibition a little weak manure water may be occasionally given. I have tried numerous natural and artificial guanos, &c., in some instances without any perceptible benefit, and in others with positive injury. The most simple and useful agent is superphosphate of lime, reduced to fine powder and stirred in the water; or a small quantity of sheep manure used in the same way. I am aware that many connoisseurs have been at first delighted with the luxuriant foliage of their plants traceable to potent doses of liquid manures of varied name, but the apparent benefit has in almost all instances been realised at the future risk of the health of the tubers. I am not adverse to novelties because they are such, but to the experimentalis would speak the language of caution: try your hand on a small scale only; never apply a new nostrum on a larger portion of stock than you can afford to lose.

Shading.—To obtain perfect blooms, a shade of hurdles, netting, or white calico, or tiffany, should be used, when the blooms begin to expand. It should be so placed as to admit of abundance of air, be secured from disturbance by winds, and be removed in cloudy weather, and at night. This will not only prolong the period of flowering, but increase the size of the blooms. The varieties having light grounds will sustain the rays of the sun much better than those with dark grounds. Even gentle growing showers in the early stage of flowering are admissible with great advantage to the plants, and without damage to the blooms of the light kinds; but the dark coloured sorts are extremely susceptible of injury from sun and rain. This fact renders it expedient for the cultivator for exhibition to plant a separate bed of the dark selfs, which will enable him to make a more perfect provision against the evils here referred to; the covering used for this bed could not always with safety be removed at night. Many sorts will produce more flower-buds than should be permitted to mature; the lateral buds should therefore be pinched off when young, leaving two or three leaders to each root.

Flowering Season.—We are now advanced to that period of culture which is to remunerate the florist for his previous solicitude. Every expanding blossom of new variety, or the re-appearance of an old but esteemed face, will afford renewed pleasure to the ardent lover of Flora. This is the proper—indeed the only season at which an entry of the particular characteristics of each sort can be entered in the florist's catalogue. Memoranda are valuable, whether of the general points of culture and their results, or of the properties of individual flowers, and I conceive they will always be found worthy of the small time necessary to record them.

Taking up.—In wet seasons the roots may be lifted as soon as the foliage turns yellow, but if the weather be dry, they may remain till it becomes brown. The Ranunculus is apt to vegetate again immediately after it is brought to a state of rest; care is therefore required when the weather is moist at this season to select and take up the sorts as they ripen, and not to wait until the whole are fit. Some varieties are especially prone immediately to vegetate; such should be lifted with soil attaching, potted in dry earth, and kept in the seed-room or greenhouse until matured.

Sowing.—The compost for seed should be a moderately light loam, to which may be added a sixth part of leaf-mould or Willow earth; the soil should be carefully sorted over to free it from insects of any kind. If the soil can be exposed and frozen through, or put into an oven and baked, it will free it from worms and larvæ of insects. Sow in boxes or pots not less than 5 in. deep. Put some coarse siftings at the bottom of the boxes for drainage, and then fill up with your compost, which should be broken but not sifted. Make the surface quite level, and press it gently with a board; then sow the seeds about ½ in. apart, and water with a finely perforated rose water-pot to make them lie flat; then sprinkle with fine dry mould, just sufficient to cover the seeds, which should not be more than the thickness of a shilling below the surface.

Turban Ranunculuses.—These are a class somewhat hardier in constitution, as well as coarser in texture, than those of which we have been treating; there are five or six varieties only, but their large and bold blossoms of brilliant colours make them worthy of cultivation. They may be planted in a border in October or in January, and in winter covered with a stratum of decayed leaves. In other respects they may be treated as directed above.—Carey Tyso, Wallingford.

Fortune's Clematis (C. Fortunei).—This is one of the best of Clematis for training on walls, poles, or fences. It bears large double white blossoms, which emit an agreeable perfume. As the flowers get fully developed, they acquire a rosette-like form, whilst the petals become tinged with pink. To grow it well it requires deep, sandy, and well manured soil. During hot weather a mulching of half-rotted manure or leaves will be of great advantage. It requires no further pruning than merely removing weak shoots where they are too thick, and shortening back any branches which are unripened or soft at the extremities. This should be performed in early spring. During winter a few inches thick of coal ashes laid over the roots will be beneficial in keeping the roots warm. The plant may be had at most nurseries noted for trees and shrubs.

Fortune's Double Clematis (C. Fortunei); flowers white and sweetly scented.

Hardy Flower Roots—These meet with a ready sale all through the spring months, and amongst them none are more popular than double red and white Daisies. These are treated as follows:—In the month of May the old stock roots are taken up and divided into single crowns, which are immediately planted with a dibber about 6 in. or 8 in. apart, on light, well dug and manured land, and if the weather is dry one or two good soakings of water are given them. They soon strike root when they are kept well hoed and clear of weeds, all straggling blossoms that may appear being pinched off. In August they are again taken up and parted, and replanted as before in a warm, sunny situation; if a little sheltered from cold winds so much the better. In this position during February, March, and April, they will be in perfection, and are then taken up as required, with as much earth as possible adhering to their roots. They are then packed in single layers in fish boxes, which hold about three or four dozen roots each, and in this manner they are sold, the average wholesale price being from 4d. to 6d. per dozen roots. These seem small sums, but such plants can be grown so close together that the quantity to be produced on, say, an acre of land is enormous. There is a pretty variegated kind called by some the Aucuba-leaved Daisy, which makes a good edging for a border, and is well worth growing.

Mignonette in the Garden.—Mignonette is a most capricious plant, in some gardens growing like a weed, in others refusing to grow at all. "Mark" may succeed by sowing his seed in pots—soil rather poor and gravelly; and when the seedlings are a fair size, plunging the pots wherever he wishes a clump of Mignonette. Transplanting never answers.—A. B. C.

GLASSHOUSES & FRAMES.

PELARGONIUMS FOR WINTER.

Those of the Tom Thumb type are the best for forcing; for, though their trusses are not large they answer better for bouquets than larger ones. Christine, too, is useful, and of a favourite and showy colour. These, with a few white varieties, and one or two intermediate shades, will be found useful for furnishing blooms in winter. As a rule, those kinds which flower freely out-of-doors will be found to be best for forcing, and I always select a number of plants for the purpose when we have done bedding. Some of the new ones of Pearson and Denny have fine trusses, but all do not flower freely in winter, though excellent for autumn decoration. However, it is safe to have as good a stock of plants of different kinds as may be found convenient; but none will flower well in mid-winter if they have not been prepared for it. The plants may be selected and potted about this season. Six-inch pots are a proper size for them, and they should be well drained. Use a good loam, with a little leaf-mould, or peat and sand, and pot the plants moderately firm, particularly under the roots, and afterwards plunge them out-of-doors in ashes in a sunny situation. During the summer let them be liberally watered now and then with liquid manure, not too strong. Those shoots that are leading too much only need be stopped; but if the plants grow pretty regularly in shape, it will only be necessary to keep the flower buds picked off constantly till about the middle of October. By this time the pots will be filled with roots like a Strawberry pot, the wood well matured, and every shoot disposed to flower. No plants should now be transferred to the house; a dry, airy greenhouse or vinery is a good place, and they may be allowed to come into flower by the time flower buds are over, or to succeed the autumn-flowering stock. As winter advances, however, an ordinary greenhouse temperature of from 45° to 50° will be too low for them. The Pelargonium must have heat and light to bring the flowers out successfully. A back shelf of an early Vinery will suit them, and while they are kept freely watered at the root, syringing overhead must be avoided when damping the Vines. Forcing during the dead of winter is sluggish at the best, however, and the secret is to have plenty of plants in moderate-sized pots, and force as many as can be accommodated, according to the demand for flowers. For use in February, March, and April I have sometimes depended entirely on old plants lifted from the beds in November, or before they got frosted. Big plants of Christine and other compact-growing sorts produce an excellent display in spring, and afford plenty of cutting. When taken up in autumn, however, the branches must not be cut back. The plants, if very large, may be reduced in circumference, but no shortening of the shoots which are left should be allowed, or they will not flower so soon or so well. I lift them, and squeeze them into as small pots as possible—generally 5-inch or 6-inch—and put the plants into a smart heat to get rooted. This accomplished, they are stored in the cool, dry houses, where they get hardened a little, and we draw off the stock as required. Christine is particularly useful in this way; it is a variety that comes in rapidly when it does flower, and I can assure your readers there are few plants which light up a conservatory more effectively in spring, when a number of large plants are placed among the other specimens all over the house; and no kind of decoration is more easily kept up. J. S.

Bougainvill . glabra.—This, grown as a pot plant, is highly ornamental, and conforms readily to almost any kind of training, as it may be grown in the loose pyramidal form or on trellises. The former, however, suits its habit best, and shows off its rich mauve-coloured bracts to the greatest advantage; but to get them in this shape they must be grown from the first much in the same way as a well-managed Fuchsia, in order that they may be thoroughly furnished with side branches. Before starting them into growth these should be pruned back to a single bud, and those that are misplaced or superfluous should be thinned out, to allow plenty of room for the new growth. If placed where they can have plenty of light and full exposure to the sun, they make firm, short-jointed shoots from 1 ft. to 2 ft. long, laden with bloo

When in this condition, few plants are more valuable or effective for conservatory decoration, where, if properly hardened before being placed in a cool temperature, they will last at least two months in good condition, and their flowers will come much brighter coloured than if subjected to a closer and warmer atmosphere. Bougainvillea glabra flowers freely in a small state, and cuttings put in now will, if grown freely on during the summer, make useful plants for next season. Any of these that are planted out, or in large pots where they are making much growth, should have the weakest shoots thinned out, that the necessary light and air may be admitted to the others to induce plenty of bloom. As a pillar or roof plant in warm conservatories, it is most valuable, provided it can be planted in a light sunny position. To check the exuberant growth these plants invariably make unless their roots are confined to a very limited space, they should only be afforded sufficient water to keep them from flagging severely, a course of treatment that has a very beneficial effect on them.

Fuchsia Sunray.—This is among Fuchsias what Mrs. Pollock was among Geraniums when it first came out. It is a free-growing neat-habited Fuchsia, furnishing well as it grows, and naturally forming a pyramid if not pushed too much in heat. The leaves are broad, regularly and distinctly splashed with creamy-white and green, suffused with crimson, especially at the points of the young shoots, a circumstance which gives the plant a distinct and highly ornamental appearance. The variegation is constant, and the different shades are more distinctly produced when the plant is grown in the greenhouse, and well exposed to the light, than elsewhere. Generous treatment and a good soil increase the size of the leaves without affecting the variegation, and, as the flowers are unimportant, it is best to pick them off, as they only weaken the shoots. Cuttings of this variety strike freely in the usual way, and should be potted off singly; small plants, about 1 ft. high, look best, and are most useful.—C.

Violets in Pots.—The possession of such varieties of Violets as the Czar and the new Victoria Regina gives quite a new aspect to the culture of Violets in pots. The old Neapolitan, though likely to hold its own against all comers as regards sweetness and free flowering habit, was hardly adapted for pot culture; it thrives in a bed of good soil in a frame, but in pots it is apt to become somewhat shabby, being subject to red spider, and a weak grower, a great drawback to pot plants of any kind. With the varieties of the Czar type it is, however, different; they have robust, bold, and erect foliage, which fills and looks well in a pot, and they are sure bloomers, and throw their flowers up well above the leaves, stand forcing better, and bloom in great profusion. I have just lifted a quantity of last year's roots of the Czar and Victoria Regina, sub-divided them, using both the old crowns split up and rooted runners, and potted them in 5-in. pots in good light rich soil, and hope to have them in flower early in the winter without much forcing. I used to content myself with lifting the roots out of the ground and forcing them at once; but, like Strawberry plants, prepared ones succeed best. The plants should be plunged in ashes during the summer, or at least set thickly together—to keep each others' roots cool—in a rather shady situation. They should never be exposed to the full force of the mid-day sun, and should at all times receive plenty of water at the roots. Before the weather becomes so severe in autumn as to injure the foliage, the plants should be moved into a cool frame (fi[illegible]eat will hardly be needed), and from such quarters they can be introduced into the greenhouse or conservatory as required, when they will continue to produce flowers for a long period if they be properly attended to, and, above everything, kept near the light.—S.

Renovating Lawns.—It is astonishing how long a lawn will retain its verdure without assistance in the way of manure. But a starved sward is never a green one, and greenness and freshness are everything in a lawn; and upon the whole it is not difficult to keep it in that condition, for, however neglected it may have been, it quickly responds to stimulating treatment. The best and most convenient plan is to apply artificial manure of some kind in the form of a top-dressing. Guano is good, but it does not produce the greenest verdure; soot surpasses it in that respect, and it is cheaper. It is not needful to top-dress the lawn annually, and when necessary most gardens should provide the materials. If all combustible rubbish in the way of prunings of trees, rakings of shrubberies, &c., be collected into a heap, they will serve not only to consume themselves, if set fire to, and produce a good quantity of wood ashes, but will reduce to ashes all the short Grass that has come off the lawn, weeds, roots and other rubbish, and at the same time burn a considerable quantity of soil, which may with advantage be mixed with the ashes and the whole applied to the lawn as a top-dressing. There is hardly anything better than this for Grass, and its effects are more lasting than guano or soot alone, and it may be applied without fear of injury. Should the lawn be mossy, it should be well harrowed with a rake first, and then cleaned and dressed.—C.

American Senna (Cassia marilandica).—This is a showy hardy plant, and its distinctive characteristics render it suitable for the herbaceous border. It grows from 3 ft. to 4 ft. in height, and produces abundance of bright yellow flowers in clusters. It is an attractive plant, and has been apparently overlooked, as it is rarely seen in catalogues, and consequently would be very scarce in private gardens. The leaves are sometimes used as a substitute for the common Senna, but the true drug is procured from Cassia orientalis.—P.

The American Senna Plant (Cassia marilandica); a hardy plant, flowers yellow.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 31.—Sowing Snowball and American Red-top Turnips among Currant bushes; planting White Cape, Walcheren, Hammond's White, and Grange's Cauliflower; also Backhouse's White, Dilcock's Bride, Knight's Protecting, Reliance, and Cornish Broccoli; plunging pot Roses in the sun, in order to get their wood well ripened; mulching Strawberries and Raspberries; earthing-up Potatoes, Peas, and Cauliflowers; syringing Azaleas infested with Thrips with Gishurst compound; manuring and digging land for winter Greens; tying Bath Cos Lettuce; thinning Leeks; watering main crops of Strawberries, and afterwards netting them; also thinning Beetroot, and hoeing among Globe Artichokes; sowing Canadian Wonder French Beans; potting off seedling Petunias; planting out dwarf crimson Celery.

June 1.—Sowing Calceolarias, Cinerarias, and Primulas; potting on Balsams and Fuchsias; pricking off Cauliflower plants; turning over gravel walks to give them a fresh appearance; cutting turf for layering Strawberries; looking over Cucumbers and Melons, stopping them, and fertilising them when required; giving all inside Vine borders where the Grapes are swelling a good soaking of guano water; cutting dead branches out of Apricot trees, and spreading out those left to give them a better appearance; shifting established Petunias into their flowering pots; planting Scotch Kale, Cottager's Kale, Brussels Sprouts, Savoys, and Autumn Cabbages; also May-sown Lettuce; putting in cuttings of Anne Boleyn Pinks under hand-lights; top-dressing pot Roses with horse-manure and loam, mixed together in equal quantities; cutting Laurels, and edging and raking flower beds and borders; sticking Scarlet Runners and Peas, and hoeing between rows of Parsley.

June 2.—Sowing Giant White Cos and All the Year Round Lettuce; also early white Naples Onions for drawing young; planting Brussels Sprouts, Savoys, and Cauliflower plants; looking over Peach and Nectarine trees, picking off curled-leaved, and washing the trees with the garden engine; clearing off Spinach and getting the ground dug up and manured for winter Greens; weeding and hoeing amongst all growing crops; potting Caladiums, Panicums, and Alternantheras for dinner-table decoration; also potting Ten-week Stocks and Asters, and shifting standard Heliotropes into 12-in. pots for conservatory decoration during the autumn; sowing Broad Beans amongst Currant bushes; planting Black Hamburgh and Muscat of Alexandria Vines; pricking out Wall flowers; turning and watering manure for Melon and Cucumber beds; staking Carnations, Pinks, Dahlias, and annuals; watering early Peach house and exposing the fruits which are ripening to the full influence of the sun, leaving more air on the house night and day; plunging Tuberoses that are coming into flower in pits; raking round Rose trees and preparing more land for late Peas.

June 3.—Shifting large Cockscombs into their flowering-pots; planting vegetable Marrows and Tomatoes; layering Keen's Seedling and Garibaldi Strawberries in 4-in. pots; putting in cuttings of Kalosanthes, double Wallflowers, and Salvia splendens; staking Heliotropes; hoeing among Gooseberry and Currant trees; also between Raspberries; sticking more Peas, Beans, and Scarlet Runners; watering flower garden thoroughly where the soil has become dry; pegging down all plants that require it; thinning Plums, Peaches, and Nectarines where not already done, and nailing in the longest of the shoots; sowing Chervil, Radishes, and Mustard and Cress; potting off Tomatoes struck from cuttings; thinning out and transplanting Parsley; also Spinach and Turnips; commencing layering Vicomtesse Héricart de Thury Strawberries on pieces of turf 4 in. square; looking over Vineries, stopping the laterals, and thinning the berries where required; getting the netting put over late Strawberries; looking over Apricot trees for snails and grubs; gathering Gooseberries for bottling.

June 4.—Taking up Chrysanthemums from open ground and potting them for conservatory decoration, and shifting Globe Amarantus into 10-in. pots; sowing Radishes, Lettuces, and Mustard and Cress; planting Cauliflowers in heavily-manured trenches; putting in cuttings of Begonias and other fine-foliaged plants; thinning Onions and Turnips; earthing-up Cucumbers; clipping Yew trees, and weeding and hoeing old Asparagus-beds; washing Camellias, in order to free them from black fly; sowing Turnips and Spinach; planting out Sweet Basil on a south border; thinning out late-sown Beet and Salsafy; commencing clipping Box edgings; putting Camellias and other greenhouse plants out under north walls; nailing in the leading shoots of Plum and Cherry trees, and washing them well with Quassia water to kill green fly; earthing-up late-planted Potatoes.

June 5.—Tying down the leaders of Cordon Apple trees; getting out trenches for the late crops of Peas; also trenches for Celery, and getting the manure into them; commencing planting out tender carpet bedding plants; potting a few Roses into 12-in. pots, and shifting latest-struck Chrysanthemums into larger pots; sowing Neapolitan and Drumhead Cabbage Lettuces; also Paris Green and White Cos; planting April-sown Cabbages and Cauliflowers; also Ice-plants and gourds; pricking off seedling Primulas and placing them in a cool frame; dusting soot and lime on Onion beds, with a view to keep down the maggot and improve the health of the plants; thinning Apricots a second time; watering orchard-house trees, also Strawberry-bed; picking insects off wall fruit trees, and afterwards syringing them with soft water.

Glasshouses.

Cool Orchids.—For the next two months or so the advantages of having a house less fully exposed to the direct action of the sun than when facing the south, or a span-roofed erection standing in the usual position, will be apparent, as most of the plants thrive better with less heat than is all but unavoidably present in houses thus under the influence of the sun, on which latter it will frequently be requisite to use blinds somewhat thicker than would be otherwise advisable, but where this becomes a necessity they must never be drawn down when they can be dispensed with. Such species as Masdevallias will now require a maximum of water, whilst Odontoglossums and allied species will need the material in which their roots are placed kept fairly moist. The plants will be better for air, more or less, being admitted to the house night and day.

Pelargoniums and Fuchsias.—Those large-flowered Pelargoniums that were some time ago recommended to have the points of their shoots pinched out, so as to induce their flowering after the earlier bloomers were over, should now have weak manure water given them twice a week; if neglected in this respect the lower leaves will assume a sickly yellow condition, and the flowering be proportionately deficient. Fuchsias struck from cuttings in the spring, and required to bloom late in the summer,

should again have the points of their shoots pinched out, and any flower-buds they may have formed picked off; neither must they have their roots confined in too small pots, as this, more than any other cause, will stop their growth and induce them to form flowers sooner than they are required. The earlier plants that are now blooming should have all seed-pods picked off as soon as the flowers have dropped, as the production of seeds is more exhausting to Fuchsias than flower-bearing. Give them liquid manure every other time they are watered, but it must be in a highly-diluted state, as if given them so strong as many plants will bear it causes the flower-buds to drop off. A free use of the syringe two or three times a week will keep red spider in check.

Flower Garden.

The principal operation connected with this department, viz., that of planting the various beds, borders, baskets, and vases with their summer occupants, should now in most cases be finished; and it is more than ever necessary that order and neatness should be maintained. Lawns at this season are often much disfigured by Daisies; and during dry weather, when Grass does not grow very rapidly, the Daisy rake will be found very useful. Plantains and other broad-leaved weeds should now be eradicated, if possible; and this may be done by cutting their heads off with a sharp knife, just under the surface of the soil, when they may be drawn out, and the space they occupied will be taken possession of by the finer Grasses of which the lawn should consist. Box edgings should now be cut. It is seldom advisable to do this sooner than about the present time, as the slightest frost occurring soon after the operation has been performed will inflict so much injury upon them as to make them look unsightly for some time afterwards. Bulbs of Hyacinths and Tulips may now be taken up and stored away. Peg down the shoots and regulate the development of such plants as Verbenas and Petunias, in order to get the surface of the beds covered as speedily as possible, when less water will be necessary than at present. Regulate also the growth of climbing Roses, Honeysuckles, the new and beautiful Clematises, all of which are worthy of a place in every flower garden. Where a stock of the various kinds of spring bedding plants was not divided or otherwise increased when taken from the beds, that may be done now, or as soon after this time as possible. Such kinds as the following may be divided, if desirable, to an almost unlimited extent, viz., Viola cornuta and lutea, Aubrietia deltoidea, deltoidea variegata, Campbelli, greca, &c.; Myosotis dissitiflora, Omphalodes verna, Phlox verna, Gentians, Hepaticas, hardy Primroses, Oxlips, &c. The two last-named will now be out of flower; but the best varieties should have been marked, and should now be increased accordingly. All these, together with the various double and single Wallflowers, should have what little attention they may require in the reserve garden, which is also the proper place to test, during the first season, the numerous novelties in the way of bedding plants which are annually introduced, and which are generally sent out in the form of very small plants in May. As soon as they are received they should be re-potted, and have every necessary attention; and, where they have been well treated, such plants will now be sufficiently established to be planted out in this department, in order that they may furnish cuttings at as early a period as possible.

Auriculas.—It is now too late to save seed, but those who have any should sow it at once, and thus a season may be gained. Sow it in pots or pans, and in either case drain well, placing some Moss or fibre over the drainage, to prevent the compost from mixing with it. This is quite necessary, as the seeds will not all vegetate for a whole year. The soil should consist of sandy loam and leaf-mould, with sand added if necessary. Make the compost quite level on the surface, and sow thinly, just covering the seeds with fine soil. The pots should be plunged in a very gentle bottom-heat and be covered with a Cucumber frame or hand-light. With the warmer weather which we are now experiencing, considerable attention must be paid to watering and keeping green fly in check, for if it increases it will seriously cripple the plants.

Carnations and Picotees.—Plants of these in pots are now all out in the open air, and, for the present they require no more attention than seeing that they are freely supplied with water at the roots, that is, those plants that show by strong growth that there there is also a corresponding root action. A few varieties make but little growth; and unless water be very judiciously supplied to them they will speedily cease to exist. If the weather be very hot, let the plants be syringed freely at 5 p.m. The surface of the beds planted with Carnations &c., should now be stirred, and a little fresh dressing applied; equal parts of loam and rotten manure answer well for this purpose.

Phloxes.—Amongst all tall-growing hardy herbaceons plants, none are so effective as decorative objects in pots as these. They now require a good deal of attention. See that the stems are secured to sticks, and if the pots are well filled with roots, some rich dressing must be placed on the surface of the soil. Give plenty of water, never allowing the pots to become quite dry. Fully expose the plants to the sun, and if the pots are plunged in Cocoanut fibre refuse, or some similar material, less water will be required.

Pentstemons, Pyrethrums, Aquilegias, and several other hardy herbaceous plants do remarkably well in pots, and are all useful when in flower as decorative plants for the greenhouse. The treatment which they require is much the same as that described above for Phloxes.

Polyanthuses.—Those who have their plants still in pots would do well to place them out-of-doors in the open border. Turn them carefully out of their pots, and plant them without breaking the ball of earth. Ours are already well-established, and are making an excellent growth, showing that they have laid hold of the rich new loam provided for them. Examine the leaves, and if they are infested with red spider this pest must be destroyed, or else it will ruin the plants. Wash the leaves with soapy water. Green fly is also fond of the Polyanthus, and must be removed in the same way.

Outdoor Roses.—Those possessing even small collections of outdoor Roses, if they have through the spring taken means to destroy aphides and the Rose maggot, will reap the benefit of the comparatively little labour required by a good display of early flowers; whereas in the absence of such attention, the whole of the growth, both leaves, shoots, and flowers, is so smothered with these insects as to prevent the possibility of well-developed bloom. Where Roses have been neglected, unless immediate means are taken to destroy the aphides now existing, and also the broods of those that will come successionally into life, it is futile to expect a satisfactory autumn bloom. In the cultivation of Roses, more than most plants, those who give the requisite attention to even a moderate number realise very much more pleasure from the results of their labour than where a greater quantity are grown, yet do not receive sufficient attention at the critical time when the young growth is beset by these pests, which are inseparable from the cultivation of Roses.

Fruit.

Vines.—The thinning of late Grapes should not be deferred a moment after they are ready, as growth goes on so rapidly that they soon get too large to admit of expeditious or neat thinning. The lateral growths on Lady Downes are now produced so rapidly, that unless repressed by stopping once a week, they become a complete thicket, and when cut off a check to the Vines must necessarily be the result, and as a matter of course the crop is more or less injured. Houses in which the Grapes are commencing their second swelling should be shut up very early with an atmosphere well charged with moisture, and if the borders are inside, well soak them with manure water, and as this should be the last application of manure, it may be applied rather stronger than heretofore. Houses containing ripe fruit should be kept as cool as possible compatible with the preservation and health of the foliage. All lateral growth should be persistently stopped, but the leading shoot on each Vine should be allowed to ramble at will.

Kitchen Garden.

Parsnips, Early Carrots, Turnips, Leeks, and Onions are some of the seedlings that now need thinning, after which, deeply stir the soil between the rows to induce a quicker and more vigorous growth. Peas suffer from overseeding as much as anything. When the haulms are 2 in. or 3 in. apart they bear pods to the very bottom, which obviously would not be the case were they clustered together. Earth up and stake such as need support, and sow for succession such kinds as British Queen, Veitch's Perfection, and Champion of England. If sown in shallow trenches, waterings and mulchings (both requisite in warm dry weather) will be the more effectual. The principal crop of Runner Beans should now be sown; 6 in. apart in the row will be quite near enough for these, and if the points be pinched out when 2 ft. high, that will ensure the production of pods from the very bottom of the haulm. Earth up Potatoes. If high culture be aimed at, strew between the rows guano or soot; stir deeply with a fork, and, after a good rain, earth up. The haulm should be thinned out to single or, at most, double shoots, and then, though the tubers may not be quite so numerous, they will be finer and of a more equable size. Top Broad Beans, in order to induce earlier formation of pods, and to prevent an attack of black aphis, which invariably takes possession of the tops of these whenever the season is favourable to their development. Unless Broad Beans be in special request, no more should be sown, as at the time when they would be ready there will be abundance of better vegetables. As ground becomes vacant, prepare and re-crop it with Coleworts, Cauliflowers, Early Broccoli, Brussels Sprouts, and Savoys; the two latter will stand the severest winter, and should therefore be planted in quantity. Early Broccoli and Cauliflowers continue in use a limited time only, so these should be planted successionally, and only in such numbers as will meet the demand. Established plantations of Horseradish, Seakale, and Rhubarb that are throwing up flower stems should have them cut off, and the ground receive its summer mulching of manure. Weeds may be kept down on Asparagus plots, and at the same time the roots benefited by an occasional light sprinkling of salt. Sow Lettuce where it is to stand, and thin out the plants to 9 in. apart. Tomatoes, ridge Cucumbers, and plants of similar hardiness may now be planted. During favourable weather keep the hoes going, in order to keep down weeds, which, now that rain has come, will grow apace.

IMPROVED FLOWER GARDENING.

THERE has been some discussion on this subject in *The Garden*, which, as it is fairly summarised in the following letter, with rejoinder in italics, we reproduce. Mr. Grieve is the advocate of bedding-out; while "Justicia" holds that all the beautiful hardy plants should be represented, not necessarily in the way bedding plants generally are, in parterres in front of the house, but in groups, beds, and positions suited to them; in fact, growing them where they would look and do best, and without striving to conform them to any pattern of beds. He also holds that the result obtained already in the parterres is as inartistic as it is geometrical. He objects to the annual planting of a number of tender plants, as being very expensive and leading to all the force and means of the garden being given to produce a temporary result. He holds that, as a system, all good gardening must be managed in an entirely different way—the main efforts and the skill being spent on forming permanent and well-considered arrangements of hardy subjects, and that what is called "bedding-out" is, in proportion to this aim, deserving of minor attention:—

Your correspondent speaks "of the little bits of feeble spring bedding which one sees here and there." In various parts of the country, however, such as at Belvoir Castle, Heckfield, and various other places which could be named, such attempts, according to all accounts, are far from being feeble. [*Spring bedding, as usually carried out, is more refined in colour than summer bedding, and good, as being carried out with hardy subjects. But it gives nothing equal to the beautiful effects that may be secured by grouping hardy flowers in natural and artistic ways. It, moreover, involves the costly, yearly or twice-a-year labour which I have often shown is a huge waste in summer bedding. Spring bedding is also geo-*

metrical; the best spring gardening need never be so.—J.] But neither spring nor summer bedding need in any degree be considered as antagonistic to the planting of permanent and artistic groups of hardy flowering plants in suitable situations; while much may, no doubt, be done in the way of supplementing such groups by the annual addition of bulbs in spring and tender plants during the summer months. [*Every kind of bedding-out is antagonistic in all ways to true gardening, because its insatiable maw absorbs year after year fruitlessly the means (often most ample) that ought to be devoted to adding to the beauty, the riches, and the lasting embellishment of the garden.—J.*]

It will in no degree increase the popularity of any other system of decoration to merely condemn its rival—if rival indeed it be, which I am inclined to deny, as, generally speaking, there is room enough in most establishments for all systems should they be desired. [*That other things than bedding-stuff should find a place is what I have asked for all along. But can any one seriously say that the planting of, say,* 70,000 *tender plants in May to perish in October does not interfere with the planting on a scale befitting the merits of the hundreds of lovely hardy flowers, bulbs, flowering-shrubs, &c., that do not perish in October, but live for many years?—J.*] "Justicia" further says that I "will not admit, or do not know, that many lovely hardy plants bloom in the prime of summer." Now, the first part of this sentence I have never refused to admit; and as to the latter, I know perfectly well that such is the case; and I also know that the loveliest of them retain their beauty for only a very short time; and this is precisely the reason which compels those who practise summer bedding to reluctantly decline their use. "Justicia" also says "that if I go to any good collection of herbaceous plants round London in the warmest summer I would find as many as I could enjoy in one day." This I do not in the least doubt; and I might not unlikely be so enamoured of their beauty as to be induced to repeat my visit to them in the course of a week or so, when I would probably in too many instances find the beauty of many of my favourites sadly on the wane. [*Daffodils bloom over a period of ten to twelve weeks; Lilies of different kinds for four months or more; Irises are lovely for nearly two months, without counting the very early ones; Delphiniums bloom for a long time, and give a good second bloom if treated properly, as do Pyrethrums, Globe-flowers, and other plants. Numbers of hardy plants bloom for a considerable time, and are beautiful in the bud stage as well. And what to Mr. Grieve is a demerit—not flowering in a stereotyped manner throughout the summer—is to other lovers of Nature one of the greatest charms belonging to flowers. As the Cuckoo-flower succeeds the Wood Anemone, so is it delightful to see the garden flowers pass one after another in their seasons.—J.*] I am perfectly aware of the great wealth and beauty of the hardy flora of temperate regions; and the gardens of this country are still being enriched by valuable introductions, possibly not more rapidly than is desirable. Extensive, although not always very select, collections of these plants existed, however, in this country long before the advent of the bedding-out system. As has been said, this collection of plants was more comprehensive than select, and contained many plants which might possibly have been interesting to a botanist, but which the most enthusiastic admirer of the flora of temperate regions would hardly have ventured to pronounce decorative or at all ornamental; and these were the plants, viz., coarse and terribly tall Asters, Epilobiums, 5-ft. Solidagos, &c., which the bedding-out system has driven from the garden. And I think most of your readers who may have known them will say that it served them right, as they had no business to be there; and "Selection, not collection," is now, and ought to be, the motto of the flower gardener. [*Mr. Grieve does not say a word here of the hundreds of lovely plants which were driven out and kept out by the same system. To many of these his best bedding plants were as showy weeds—devoid of associations, form, or fragrance. The hardy Lilies alone are worth the whole lot, not to speak of catalogues of other beautiful flowers, too long excluded by a system false to Nature and art, and opposed to every true interest of the garden.—J.*] In a former communication upon this subject, I think I disapproved of attempting to carry out two distinct systems of bedding—viz., that of spring and summer in the same set of beds; although this is done, and well done too, in some establishments, but it demands much labour, and is seldom satisfactory, the one system seriously interfering with the other. There is nothing, however, to prevent the site of the summer flower garden assuming during winter the character of an arboreal garden, the beds being furnished with hardy trees and shrubs with ornamental foliage and graceful habit of growth, which is all that can be reasonably expected or desired as an out-of-doors winter garden in this country. In many establishments this system is to some extent practised, and will no doubt ere long become general. An excellent example, which ought to prove a powerful stimulus to the same, was exhibited at South Kensington, on the 14th of last October, by Messrs. Lee, of Hammersmith. This consisted of a beautifully arranged geometric garden, the beds of which were furnished with small hardy plants of distinctively coloured leafage, and margined with dwarf Box or the green-leaved Euonymus microphyllus, the whole being relieved by pyramidal plants of Cupressus Lawsoniana argentea, Taxus fastigiata aurea, &c., together with standard variegated Ivies, standard Aucubas (bearing bright red ripe berries), and many other beautiful and interesting plants, well suited to the purpose in view. [*Here again we have geometry and endless labour. Who that has the true spirit of the gardener within him, and has eyes to see the many gardens beautiful at all seasons without such complications, can contemplate without dread this twice-a-year transferring of a number of hardy young trees and shrubs, and providing a place for them in the meantime? Just imagine what could be done for permanent good in beautiful planting with the means necessary to carry out such costly "arboreal gardening" as this! And, granting that people are rich enough to do it, what then? Why, probably in a neighbouring rectory garden, where no such nursery-like moving about of the poor shrubs was ever thought of, we should find a real "arboreal garden" on the turf, far beyond the highest triumphs of the bedder-out of shrubs.—J.*]

A few words more and I have done with the subject of summer bedding, which, with all its shortcomings, I believe to have had very much to do with the fostering of a love for flowers among all classes of the community to an extent which certainly did not previously exist. The humblest cottager now carefully preserves his zonal Pelargoniums, Fuchsias, &c., as window plants during winter, with the view of their decorating his little front garden when summer again returns. And this preservation is often accomplished at the expense of considerable trouble, such as their nightly removal from the windows to places of greater safety. With a view of securing their vitality, I have even heard of their being placed upon the warm hob, an act of mistaken kindness which would doubtless prove too much for them. Many people, too, of limited means have been induced to erect a greenhouse or glass structure of some kind, which even the repeal of the duty on glass would hardly have tempted them to do, had it not been the desire for the means of preserving their bedding plants during winter.

P. Grieve.

[*Of all Mr. Grieve's reasons for bedding, the last is the most amusing, if not the strongest. Imagine the unhappy descendant of the owners of our once lovely cottage gardens—bright with Daffodils, Roses, Pansies, Pinks, and double Primroses, and other plants that, like himself, did not much regard the cold breeze—being obliged to carry a miserable bedding plant to a "warm hob" with the view of "securing its vitality"! I remember once speaking to the late Mr. Mowbray Morris, for a long time the able manager of the "Times" newspaper, about this very subject, and, in the course of conversation, he said to me, "With all the expense and skill bestowed upon your modern flower garden, you have produced nothing half so pretty as an old-fashioned cottage garden." This is the simple truth. But he did not refer to the cottage garden planted by sticking scarlet Pelargoniums, &c., into the raw earth three months after the real cottage garden begins to be bright with blossoms.—Justicia.*]

Method of packing cuttings.

Cuttings by Post.—What are known as soft-wooded cuttings—that is, cuttings of such plants as Fuchsias, Verbenas, Pelargoniums, Dahlias, and other popular florists' flowers—are often sent through the post in spring at a few hours notice, and the best mode of packing for such journeys may be worth attention, in order that the cuttings may arrive fresh and ready for inserting in sandy soil, or in a bed or pot of moist heated sawdust surfaced with sand, at once, with a sure knowledge that they will strike root and grow. There are several ways of packing cuttings for carriage by post, but that here represented has much to recommend it. In this case the newly-cut slips or branches are laid on a bit of fresh living Moss, moistened in water, and squeezed partially dry; the whole is then encased neatly in a piece of sheet lead or tinfoil, which retains its position without tying, and prevents the Moss from becoming dry through evaporation. For packing in large boxes only the lower half of the cuttings need be enveloped, as shown in our engraving; but, if only one little bundle is to be sent, use more Moss and envelope the cuttings entirely, both in that and in the tinfoil. A small tin or lightly made wooden box is admirably adapted for "mailing" cuttings. Such boxes are generally sufficiently strong to resist crushing or jamming on the journey. Bundles of cuttings packed in damp Moss, enveloped in sheet india-rubber, and finally wrapped in two or three folds of stout brown paper, also travel safely. In cases where a few cuttings have to be carried home in the hand, nothing beats Moss and brown paper as packing material.—B.

To Destroy Slugs.—On a damp evening lay heaps of brewers' grains, a handful in each, where the slugs resort, and visit them after 9 p.m. with a flour-dredger full of fresh dry slaked lime, and dust a little over the slugs found. From twenty to fifty have been killed on one heap in this way among Broccoli plants this year.—W. H. G.

Slugs in Frames.—If those who have Melon or Cucumber frames infested with vermin would procure a couple of toads and place in each frame they would find all vermin quickly destroyed. The toads are quite harmless, both to man and plants, and only require something to shelter them from the fierce sun of summer. They can stand any amount of heat, and are ever on the watch for worms and insects.—Geo. Came.

House and Window Gardening.

Palms in Rooms.—To preserve these in health, strict attention to cleanliness and careful watering is necessary. Every leaf should be sponged twice a weak with tepid water, well washing both the upper and under surfaces of the leaves. Water only when dry, and then give enough to thoroughly moisten the soil. The Thrinax is not such a vigorous-rooted subject as many Palms. If it receives an overdose of water, the fibres will certainly die. When once a Palm loses its leaf beauty, it is a difficult matter to restore it. We would prefer to replace it with another healthy specimen. —J. C. B.

Variegated Abutilons as Window Plants.—Among these the somewhat common A. Thompsoni is still one of the best for culture in windows. The slender and erect habit of the plant necessitates its culture in small pots, and frequent stopping of the shoots, so as to have plants about 6 in. or 1 ft. in height, furnished with leaves to the bottom. For side plants for table decoration these small Abutilons are admirably adapted, and the variegation is of a striking kind under artificial light. Still neater in habit, and more profusely and constantly variegated, is the narrow, angular-leaved A. vexillarium, which also grows slower and retains its leaves better. It is an excellent edging plant for large vases, and associates well with Maiden-hair and other Ferns in such positions. Cuttings made of the tops strike readily, and if a slender stake is put to the shoot—for it keeps to one shoot as a rule—it forms one of the neatest little plants that could be desired, and a quantity of it sprinkled throughout the greenhouse gives quite a lively aspect at any season, for it can be had all the year round. I keep all my plants in 3-in. pots, chiefly in order that they may fit into small vases; but it—and, indeed, the other kinds as well—belongs to that class of plants which will bear turning out of their pots for a few days when required without much injury. Among other ornamental-leaved Abutilons may be mentioned A. tessellatum and A. variegatum. They all strike easily from cuttings, and thrive in a compost of loam, leaf-mould, and sand.—C.

Myrtles as Window Plants.—Perhaps Myrtles have become old-fashioned; at any rate, I do not think they are so commonly grown as they were years ago. To my mind they are—whether in flower or not—always beautiful, and the aromatic perfume given off by their foliage is at all times grateful and refreshing. Under even the most ordinary management they rarely get out of health, and they may be grown for years in the same-sized pots. The Myrtle is pre-eminently a cottager's plant, and when it gains a footing in a village or neighbourhood it travels from house to house in the shape of slips, until nearly every cottage window is furnished with a Myrtle. I have occasionally come across quiet back streets, mostly inhabited by working men and small shop-keepers, where Myrtle Grove or Myrtle Place would be an appropriate title, so numerous were they. I have one such neighbourhood in my mind's eye at this moment; for two years I generally passed through it several times a day, and I made the acquaintance of every Myrtle in the place, from the small stripling that was growing in the same pot with its parent to the giant, 6 ft. high, that had to be placed in the back yard all the summer, and which cost almost as much care and anxiety in keeping through the winter as if it were really a member of the family; and I never now see a Myrtle in a cottage window without looking upon it as an index to the comfort and cleanliness within. Myrtles are very easily propagated; pieces of half-ripened wood, firm at the base, taken off at the heel and inserted in a pot of firm sandy soil, will root almost anywhere in a shady place. There is, of course, a certain degree of fitness in connection with everything, and plants that have made their growth in a low temperature are best propagated in a structure without much artificial heat. However, getting up a stock of Myrtles is so easy a matter that one need not refer to it at greater length. There are several varieties of the common or broad-leaved Myrtle, and I think two varieties of the narrow or small-leaved kind. There is also a variegated form that might be grown where variety is sought. In Ireland, and some of the milder parts of England, they will stand the winter in the open air, but, should the season be more than usually severe they are likely to suffer to a great extent, unless placed in a very sheltered position.—H. E.

Thrift on a London Window-sill.—I bought a very small tuft of wild Thrift from a mountain in the Snowdon region in North Wales about four years ago, and planted it on my return to London in a Mignonette box at a bedroom window in a north aspect, where it gets neither its bright mountain light nor its pure air, nor a single gleam of sunshine at any time of the day; and yet it has survived four London winters, with their smoke and smuts, without injury—the Grass-like leaves shining healthily in their bright dark green, and each year throwing up flowers in profusion. It has become a fine large tuft, and has twenty-three flowers in full beauty at the present moment. I know of no other plant that would defy London smoke and a dark north aspect with anything like the same degree of hardihood.—H. N.

COLUMBINES.

The Aquilegias, or Columbines, as they are called, constitute a very interesting and beautiful genus of hardy herbaceous plants. They are easily cultivated, and their graceful foliage and handsome flowers amply repay any attention that may be bestowed on them. Aquilegia vulgaris, the best known species, or some of its many varieties, is that universally cultivated in cottage gardens. There are single and double forms of it in many colours; but most frequently they are purple, reddish-purple, and rose coloured. The pure white variety of it, with large flowers and elegant pale green glaucous foliage is the best. Columbines are very easily raised from seeds, and any particular variety may be increased by dividing the roots. They all succeed perfectly in any ordinary garden soil. The annexed woodcut represents a hybrid kind, called by Messrs. Veitch & Sons A. cœrulea hybrida, obtained by crossing A. cœrulea and A. chrysantha. The result of the cross has been the production of a variety of a more robust habit than that of A. cœrulea, with sepals of a delicate pale blue and petals yellow or primrose coloured. All of the above are hardy, but they do not succeed so well in open borders as they do in pots. For culture in pots they are usually raised from seeds, and in order that good flowering plants may be obtained the following season the seed should be sown in April, and as soon as the young plants are large enough to handle they should be pricked out, about a dozen together, in a 5-in. or 6-in. pot. When these have made some growth let them be potted off singly into small pots, re-potting as the plants require it. It is not desirable to use large pots, as Columbines do not succeed so well in large pots as in those of moderate size; a 5-in. pot is quite large enough for A. cœrulea, while strong plants of A. chrysantha and A. cœrulea hybrida succeed best in 6-in. or 7-in. pots. While making their growth they may be kept in a cold frame, or they may be placed out-of-doors in an open position. If they are in frames the glass lights must be removed whenever it is possible to do so. The insect pests that chiefly attack the Aquilegia are red spider and green fly, but neither of these does much injury, and indeed they seldom appear at all if the plants receive no check, and are syringed daily with clean rain-water. The plants may be wintered in cold frames, and during the dull months they should not receive much water, merely enough to keep the soil moist. Allowing them to become rather dry and then giving them a good soaking of water is better than giving driblets and often. Permit the plants to remain in the frame until the first flowers open, when they may be transferred to the greenhouse. The rising flower-stems come in contact with the glass, and when that happens it is necessary to raise the lights a little. The soil best adapted for them is rather clayey loam, to which should be added a fourth part of leaf-mould and nearly as much rotten-manure and some sand. All the species and varieties of Aquilegia succeed under this treatment.

A. glandulosa is a very handsome species, but it does not succeed well everywhere. It succeeds well north of Aberdeen; but probably the south of England is too dry and hot for it, as it has been introduced from the mountainous districts of Central Siberia. A. alpina is rather like it in its manner of growth under cultivation; it is also from a high mountainous district in Central Europe. The plant is dwarf and the flowers very pretty.

A. Skinneri is a very distinct species, that should be grown in a select collection. It succeeds better in the open border than any other, except the common garden Columbine (A. vulgaris). It is almost as robust as A. chrysantha when grown in pots. The sepals are orange-scarlet, and the petals yellow. It flowers the earliest of all that have been named. A californica resembles the last in colour; the flowers are, however, not quite so large, and the plant is taller and of a more straggling habit.

A. pyrenaica is another free-growing handsome species, with purple sepals and bluish-purple petals. Its flowers are drooping and produced very freely. Whether for the herbaceous border or for pot culture all the above may be freely recommended. Cut flowers of them are also very beautiful in vases.

ANSWERS TO QUERIES.

2078.—**Non-flowering English Plants in India.**—Wallflowers will sometimes bloom very sparingly in wet sunless springs in India. The following treatment may make them flower:—Plant, either on a rockery or on a pile of stones sunk in the ground, and let the earth the plants root in be well mixed with old mortar, pounded shells, or carbonate of lime in some shape or form. Water very sparingly when the plants are wanted to set their bloom buds. Wallflowers will grow in pure chalk. I remember noticing some in a railway cutting in Kent growing from the vertical north side of the cut, exposed to the hottest sunshine; they were only single shoots, 6 in. long, but each bearing two or three finely coloured blossoms 1½ in. in diameter. It is difficult to account for the Sweet Williams not blooming, as, in a soil which suits Pinks and Carnations here, the difficulty is to keep them from blooming—unless they are established the previous autumn. One or all of the following treatments may succeed:—1. When the plants have reached a size at which they ought to rise for bloom, carefully lift and transplant them along with as much as possible of the soil the roots penetrate; the slight check given may have the desired effect. 2. In a poor light soil dig holes 1 ft. deep and the same in diameter; mix the soil dug out with leaf-mould and return it, and prick the seedlings out, one in the centre of each station, when they have made six leaves. Vary the quantity of leaf-mould used from a sixth in some holes to half in others, taking note of the quantity used in each, the object being to give the plants a soil which they exhaust by a certain period when they may show for bloom; when the bloom-buds show, liquid manure may be given. 3. Shade the plants from the hottest sunshine while they are making leaves, and expose them to it when they are wanted to bloom. 4. Water very sparingly when the plants have made sufficient leaves. When plants refuse to bloom, it is always necessary to bear in mind that a plant only blooms when its vital energy gets ahead of its capability of forming leaves, and act accordingly.—J. D.

2201.—**Propagating Sweet-scented Verbenas.**—Take a 4-in. pot and fill with soil, using equal parts of loam, leaf-mould and sand; than place it level inside of a 6-in. pot, filling up with soil between. Take cuttings of the freshest shoots that are not flowering, and fill the 4-in. pot; then give a good watering, using a fine rose. Cover with a bell-glass about 5 in. diameter and shade from the sun. Keep close until they show signs of taking with the soil, when a little air may be gradually admitted. Watch that they do not get too much, as they are very liable to flag. In giving water, apply it outside the centre pot.—M. Cuthbertson.

2147.—**Cowslips from Seed.**—The Cowslip is most commonly met with in damp, level, alluvial meadows; but it never grows so well or flowers so profusely there as it does in a light well-drained soil, where the plant is seldom met with. This would seem to indicate that, like others of the family, any drying up of the seed is fatal to its germination, as, other

things being equal, a plant which produced ten or twelve large trusses of flowers would have a better chance of seeding than one with one or two small trusses; whereas, in a dry soil the Cowslip does not spread but remains scarce. Treat them the same way as Auriculas. Sow in pans of loam and leaf-mould, cover with ½ in. of chopped Moss, and have patience. Like some others of the family, the seed may be a long time in germinating. The seeds of the common Primrose and of Primula japonica will remain in the ground nearly a year before they germinate, although a few seeds will generally germinate at once.—J. D.

2191.—**Plants in Rooms.**—Plants growing in rooms would certainly thrive much better could they be removed as soon as the gas is lit. It is just that dry vitiated state of the atmosphere which gas and fire heat produce in an apartment that causes the grower so much trouble, rendering it a matter of considerable difficulty to preserve plants in health when subjected to its influence. The idea of constructing a window conservatory is excellent. We have often felt considerable surprise that more should not be attempted in this way. Even where no verandah exists, it is no difficult matter to build something of that description, wherein plants may be treated more in accordance with their requirements than it is possible to do in a room. A glass roof is by no means indispensable, although if a kind of skylight could be let into the roof, so arranged as to form a ventilator, to be opened more or less wide, according to the weather, plant culture in such a structure would be thereby much facilitated. In the winter a lamp or small stove would keep out frost; and many kinds of spring-flowering plants could be brought into bloom at an early period.—J. C., *Byfleet.*

Columbines (Aquilegias).

2194.—**The Best Pansies.**—"X. Y. Z." should have distinguished between show and fancy varieties. Opinions differ as to the best; but the following six of each kind will be found good:—Fancies: Mrs. Wood, crimson, the largest Pansy out; Lady Middleton, rose and purple, white edge; Robert Goodwin, crimson, edged with white, dark-brown blotch; John Currie, bronzy crimson; Mrs. McTaggart, straw colour; Mrs. Crawley, purple, edged white. Show: Capt. Knowles, dark self; Sir P. Coats, purple self; Princess Beatrice, white self; Alex. Adam, yellow self; Rob. Burns, yellow ground; Jeanie Grieve, white ground.—M. Cuthbertson.

2181.—**Ants and Fruit Trees.**—Is "C. J. B." sure his ants' eggs are not the black aphis? A Morello Cherry on a north-west wall is almost yearly infested thus; and black ants are at that time always very busy among their sweet excretion. Our plan has always been to cut the young shoots, when they are from 6 in. to 8 in. long, off to the third or fourth bud; if there be any not infected, leave them. The lower portion of the tree is attacked soonest, and likewise it frequently receives its summary pruning earliest. This rather violent measure has apparently never hurt the tree, as it is seldom but what an excellent crop is produced. Care should be had that too much leaf is not taken off, or the crop will be a failure. Our Apricot and other fruits have never been infested with the same black aphis—V.

2175.—**Flowers and Gas.**—The only kinds of plants that are really calculated to give satisfaction in an apartment where gas is constantly burnt are those which have foliage of a somewhat thick leathery nature, such as Aspidistra lurida variegata, Ficus elastica, Dracænas congesta and rubra, and Grevillea robusta. The more vitiated the atmosphere the more frequently must the leaves be sponged with clean tepid water. Wash both the upper and under surfaces at least twice a week. Flowering plants do not thrive well in a close impure atmosphere; but they, too, may be kept in good condition for some time if thus attended to.—J. C. B.

2179 and 2196.—**Leaf Impressions.**—I take pleasure in telling my fellow readers respectively that the oil-sheets are those commonly used in copying letters, and which keep the wet part of the letter book from damping the dry part. The carbonic paper is that used for manifold writing, principally for telegrams. To my querist S. A. Bird, I may add that if my *modus operandi* is adhered to, the leaf would be found so black that it would not be known from a crow. I should be most happy to send either or both writers a sample of carbonic paper and oil sheet, so that they will know what to order, and, if they like, an impression to prove my case. Any office stationer will supply the materials named.—Jas. J. Hodson.

2227.—**Impregnating Flowers.**—If the object is simply to produce seeds, going over the flowers indiscriminately with a camel's-hair pencil will suffice. If there is a scarcity of pollen in the case of the Calceolarias, it may be obtained from any of the well-shaped flowers of the shrubby kinds. This will induce a dwarf sturdy habit. The camel's-hair brush will also do for Auriculas; but, to effect any particular cross, emasculation must be done early.—E. H.

2215.—**Cropping a Kitchen Garden.**—The sorts of Cabbage, Broccoli, &c., already in hand are good, and will give a supply of green stuff for a long time. These should be supplemented by getting as early as possible Brussels Sprouts, Scotch Kale, purple sprouting Broccoli, and in the autumn some summer-sown Cabbage for spring cutting. Winter Spinach should be sown early in August, and white Turnips through that month also. Celery, if not sown, should be sown at once in heat, as it is late; the best sorts are dwarf white, Incomparable, Fulham Prize, pink, and Leicester Red, all firm, hardy, and of good flavour. For summer use it is good time yet for runner and dwarf or French Beans, and for a few late Peas. A sowing of dwarf Erfurt or Snowball Cauliflowers now will give good heads early in the autumn before Veitch's is ready for cutting. Vegetable Marrow plants may be put out at once, as also may be ridge Cucumbers. A sowing of Short Horn Carrot made at midsummer will give some delicious roots for the early winter, and winter Onions should be sown in August for the following spring use. It is often cheaper te buy Cabbage and other winter plants than to raise from seed, as there are many risks which are always greater the less the quantity of seed sown.—A. D.

2221.—**Mushroom Growing in Meadows.**—There is not the least reason why it should not be done, although it cannot be assured that the result looked for will follow; all will probably depend upon the season, as if very dry the spawn may not run, or if wet it may perish. It will have to be entirely dependent upon the temperature of the earth, and, of course, would be in just the same position as naturally-formed spawn. The spawn should be broken up into pieces about the size of hens' eggs, and be buried about 1 in. in depth in holes that should be re-covered with fine soil; on the other hand, the same amount of spawn may be made to produce perhaps a far larger crop of Mushrooms if put into a properly-prepared bed

made up of loose horse droppings that have been frequently turned and moistened so as to secure a sweet mild warmth. This may be built up in any warm corner of the garden to a depth of about 12 in., and the pieces of spawn put in almost directly; then the bed should be surfaced to 1 in. in depth with fine soil gently patted down with a spade, and well watered; then cover up with straw and leave it, protecting only from heavy rains, and watering occasionally with tepid water if the weather is hot and dry. Such a bed will give plenty of good Mushrooms after a few weeks, but, of course, could only be available in the open air either in summer or autumn.

2224.—**Vine in Conservatory Not Doing Well.**—There is too much reason to fear that a Vine which almost refuses to break or make growth is hopelessly gone beyond recovery, and the most practical remedy would be to root it out, re-make the border in which it grows, introducing as much fresh soil as possible, and planting a new Vine. A good start at the first lays the foundation of a good Vine later on, as if the first growth is weak and puny that of later years will rarely ever be fruitful. It may be of some use to cut back the Vine hard, and, sacrificing the prospect of getting fruit one year, strive to induce fresh vigorous shoots; if these could be had, and be well ripened, then the foundation of a fruitful Vine might again be laid. There is too much reason to fear that the fault lies at the roots, which no doubt are in soil too poor, or perhaps too sour, to suit them. —A. D.

2180.—**Sowing Begonias.**—There should be no difficulty experienced in raising Begonias from seed if the following instructions are carried out. It is, however, imperative that the seed be new, otherwise but little reliance can be placed upon its germination. The beginning of February is the best time for sowing, as the plants then get a long season of growth; and if pushed along quickly will make good flowering specimens by the early autumn. Until the beginning of May a warm house is necessary, after which time a close frame or a hand-light will suffice. Well drain a 6-in. pot or a pan; then fill the same with a compost of two-thirds leaf-mould and one-third loam, adding thereto a goodly portion of silver-sand. Make the surface quite firm, water the soil, and, having allowed superfluous moisture to drain away, sow the seed thinly, covering very slightly with fine sandy soil. Place a piece of glass on the pot, and shade continually with a piece of paper until the seedlings appear. The main point is to place the pot where the soil cannot dry, but so that little or no watering is needed until germination takes place.—J. C. B.

2195.—**Best Six Roses.**—Out of the hundreds of first-class Roses in cultivation, it would be a difficult task to name the best six. A good six for garden decoration as standards would be—Victor Verdier, Souvenir de la Malmaison, Aïmée Vibert, Cheshunt Hybrid, Gloire de Dijon, and Belle Lyonnaise. For garden decoration as bushes—General Jacqueminot, Anna Alexieff, Glory of Cheshunt, Glory of Waltham, Perfection de Blanches, and Madame Devert. A good six fine show Roses, which have been out some years without being superseded by newer introductions—Jules Margottin, Alfred Colomb, Charles Lefebvre, John Hopper, Sénateur Vaisse, and Maurice Bernardin. A very high-class six exhibition Roses—Captain Christy, Marie Baumann, Duke of Edinburgh, Prince Camille de Rohan, Madame Victor Verdier, and La France.—D. J.

—— The six best H. P.'s are—John Hopper, carmine-rose; Comtesse de Chabrillant, pink; Alfred Colomb, crimson; General Jacqueminot, velvety-crimson; Marie Baumann, carmine-crimson; and Charles Lefebvre, deep crimson. The fourth is faulty in form, but makes up in other points. If other kinds are to be included, Maréchal Niel is the best yellow, and Gloire de Dijon the most useful yellow Tea-scented.—M. CUTHBERTSON.

—— Six of the very best Roses in cultivation are Souvenir de la Malmaison, Gloire de Dijon, La France, Paul Néron, General Jacqueminot, and John Hopper.—C.

2172.—**Watering Early Potatoes.**—If they are very dry, a good watering will be beneficial. Do it in the morning. I would advise you not to cover them at night unless it is very like frost. I have them on an 8-ft. border over 1 ft. high, and they have never had any covering.—M. CUTHBERTSON, *Bute*.

2193.—**The Feather Grass** (Stipa pinnata).—Your seed has been bad or you have mismanaged it. Two years ago I sowed some outside, as I would an ordinary hardy annual. Almost every seed seemed to come up, and now I have fine clumps.—M. CUTHBERTSON.

2076.—**Annuals and Perennials for Rose beds.**—See GARDENING for April 10, 1880, p. 67, and add to the list of perennials there recommended Phloxes in variety and the taller Delphiniums, and to the annuals the single and double Clarkias. Godetia The Bride would look well amongst dark Roses: so also would White Rockets and Auricula-eyed Sweet Williams amongst biennials. Convolvulus minor would look well, but does not last long.—J. D.

2165.—**Wallflowers with Double Blossoms.**—Double Wallflower or Stock seed can only be ensured from flowers with more than the normal four petals. Seed bought as single seldom produces such flowers, but among the doubles there are usually a few singles with five, six, or even more petals. All other flowers should be picked off, and seed saved only from those with the extra petals, which will be almost certain to produce double flowers.—H.

2192.—**Disease in Gooseberry Trees.**—If "John Hopkinson" examines the red spots under a microscope, he will find them to consist of minute red insects like the cochineal. The best plan (as far as I know) is to pick off the leaves and destroy them.—H. H. L.

2037.—**Window Boxes.**—Read ½-in. deal board instead of 2½ in., as mentioned p. 129, May 15. A window box made with such a thickness would be exceedingly cumbersome.—NEWT.

2204.—**Summer Flowering Bulbs.**—Scilla montana alba, Anemone appenina, A. fulgens, Summer Snowflake (Leucojum æstivum), Adonis vernalis, Sanguinaria, hardy Cyclamen, Triteleia uniflora, Grape Hyacinths. All these would succeed your spring bulbs, and be of about the same size for your Wardian case.—WESTON.

2185.—**Rose Maggots.**—There is but one effectual remedy, viz., hand-picking. Make a point of going over the trees at least every other day, examining them closely. The crumpled state of the young leaf betrays the presence of the insect.—B.

2190.—**Flowering Shrubs for Borders.**—Berberis Darwini, a handsome evergreen, bearing a profusion of bright orange-yellow flowers, and the Laurustinus would be suitable subjects for the purpose. Deutzia crenata fl.-pl. and the Japanese Privet are both very pretty; the latter is of medium growth, is evergreen, and flowers freely in the summer.—J. C. B.

2193.—**Trailing Azaleas.**—The plant alluded to is Azalea procumbens, and is to be found on many of the Highland mountains, where it is indigenous. It is a small shrub, growing in tufts, and procumbent on dry heathy ground, and has rose-coloured flowers, which appear in July. It is found nowhere in the United Kingdom except Scotland. Some of our nurserymen may have it, but I think it is very unlikely.—J. W., *Tottenham*.

2200.—**Caterpillars on Cherry and Rose Trees.**—We know of nothing so effectual as Hellebore powder, enclosing the same in a muslin bag and dusting the trees with it, choosing a still morning for the operation.—C.

2199.—**Insects in Seed Pans.**—Put a spadeful of lime in a tub of water, allowing the latter to become quite clear. Use the same for watering the pans, and the insects will either die or make their escape. There is no danger of using the water too strong, as it will only hold a certain quantity of lime in solution.—C.

2229.—**Raising Seeds.**—I want to raise some Carnation, Calceolaria, Primula, and Cineraria seeds. Am I likely to do so in an unheated conservatory? and what soil and treatment would be best?—NANCY. [Well drain some pots or pans by filling them half-full of broken flower pots; over this place some Moss or half-rotted leaf-mould or turf, then fill up with light sandy soil, press it down firmly and evenly, then well water it, and sow the seed evenly on the surface. Slightly cover with very fine soil and place in a shady corner of your conservatory, placing a pane of glass over each pan till the young plants are up.]

2230.—**Leaf Mould.**—Is there any way of reducing leaves to mould quicker than by the natural process of decay?—DERBY DILLY. [Keep them well watered and frequently turned; tread them down firmly each time after turning.]

2231.—**Window Plants not Blooming.**—I have three Geraniums which look very healthy and green in the leaf, but most of the buds when they have begun to show themselves turn yellow and fade away, and the others which have come forward have opened before they have reached their natural size.—W. L. [Give them more air and light and sun, if possible.]

2232.—**Watering Liliums.**—In growing the Lilium auratum and L. rubrum is it necessary to give much water? and about what quantity daily to single bulbs in pots? also if liquid manure would be beneficial?—AURATUM. [When the plants are growing freely, abundance of water is necessary. We could not state the quantity that should be applied, but if your pots are well drained you may give as much as you like in reason—that is, when the plants require it; and the time they require it is when the soil is dry; surely you can tell when the soil in a pot is dry. Weak liquid manure may be given occasionally.]

2233.—**Grape Vine Bleeding.**—I have a Grape Vine having three thick branches proceeding from the main stem, similar to the prongs of a fork. One of these branches has been sawn off, and the cut branch continues to bleed clear water. Will this injure the Vine if not stopped? and what is the remedy to cure it?—BLEEDING VINE. [Dry up the stem with a hot iron, and then apply a thick coat of sealing-wax over the cut. As the Vine makes leaves and wood the bleeding will stop.]

2234.—**Management of Seakale.**—What am I to do with Seakale plants that have done bearing some time? I do not know what treatment they require to ensure a good and early crop next year.—G. A. [Dig in a little manure between the rows, and keep the surface frequently hoed during summer.]

2235.—**Fumigating Roses.**—In fumigating Roses in frames is it better to syringe before or after?—H. B. [Syringe them the next day if you do it at all. The leaves of plants should always be dry when they are fumigated.]

2236.—**Wireworms in Cutting Pots.**—How can wireworms in pots, which eat away the roots and prevent cuttings striking, be got rid of?—WIREWORM. [By taking out the cuttings and putting them in soil in which wireworms do not exist.]

2237.—**Pelargonium and Geranium.**—Are these one and the same thing? or what is the difference?—W. HEINES. [They are different, but the distinction is such that none but a botanist would discover it. We use the two words often, because many of our readers would not understand what a Pelargonium is, it having always been known by the name Geranium.]

2238.—**Fruit of Cucumber Dying Off.**—My plants are healthy and grow fast, but when the fruit appears 2 in. long, they fall on the bed. Can you please give the reason? The heat is 65° by night and 70° by day. —F. M. [Imperfect fertilisation, we should say. Fertilise the blossoms at the end of the embryo fruits with the male blossoms which have no fruit attached to them.]

2239.—**Schizostylis coccinea.**—I have not succeeded in making this blossom, either by keeping it in the pot, in a frame, or planting in the garden. Please say whether it should be divided when planted out, and when this should be done, and in what soil.—M. W. M. OLIVE. [If you plant it out now in any good garden soil it should flower in autumn. You may divide it or not, according to the size of your plants. They may be lifted and potted previous to flowering if desired.]

2240.—**Pruning Rose Trees.**—I pruned all dead wood from my Rose trees in February; since then the ends of the living shoots have died down; the leaves seem dried up. What is the cause of this? and should the withered wood be cut off again?—THANKFUL. [The ends of the shoots have probably been injured by frost. Cut them back to good healthy buds.]

2241.—**Lime Water for Roses.**—What strength do you make lime water for syringing Rose trees to kill aphides?—THANKFUL AMATEUR. [Lime water is not the best thing for this purpose. Try Quassia, at the rate of 4 oz. to the gallon of water; boil them for ten minutes, strain, and add 4 oz. of soft soap. Syringe the trees when the liquor is nearly cold, and half an hour after syringe with clean soft water.]

2242.—**Lavender Hedge.**—My Lavender hedge was growing very straggling and I layered it down; the frost has killed many, both bushes and layers, and the appearance is unsightly. Is it possible to keep such a hedge trim?—SCHOLASTICUS. [We would advise you to put in a lot of cuttings, and when they have struck, cut down the hedge close to the ground and put a layer of manure on the roots, and keep it watered in dry weather. It may break up from the bottom and form a good hedge again; if it does not, dig it up and well manure the ground and plant your newly-struck cuttings.]

2243.—**Cucumbers Turning Yellow.**—What is the reason my Cucumber plants turn yellow at the edge of the leaf? Is it too much water? And please inform me the best time to water, and whether the foliage should be wetted. Should the plants be syringed? if so, should they be shaded afterwards?—TELEGRAPH. [If the frame is in a sunny position, it will need a little shade during the day. About 4 o'clock in the afternoon well syringe the plants, and also all round the frame: remove the shading and close the ventilators. Cucumbers require abundance of water during the summer, and this should be performed at least once a week; twice will be better. Give a good soaking when you do water. The water should be exposed to the sun all the morning, and used in the afternoon when you close the frame.]

2244.—**Pruning Currant Trees.**—I have a Currant tree planted against the south wall in my garden, and the young branches have grown so much that they cover the most of the tree, thereby keeping the sun off the fruit. Can I now strike cuttings?—P. L. R. [Cut off all shoots but the leading ones to within 2 in. or 3 in. of the old stems. The cuttings might strike now, but autumn or early spring are the times to insert them.]

Fumigator.—*W. W.*—If you use a fumigator similar to the one advertised in our columns weekly, you can smoke the house without being obliged to stay in it. Tobacco smoke would have an injurious effect upon green frogs.

Herbaceous Plants.—*F. W. P.*—These are plants which partake of the nature of a herb, and the stems and leaves of which die down after a few months vegetation.

Spiræa japonica after Blooming.—*Florence.*—Divide the roots and plant them out in a warm situation in deep rich sandy soil; lift and pot in autumn.

Training Cucumbers in Frame.—*A Novice.*—When the plant has made two pairs of leaves besides the smooth seed leaves which come first, pinch out the top. This will cause the plant to send out at least two shoots, which should be trained across the frame. As soon as young fruit show themselves pinch off the top of the shoot which bears them, leaving one leaf beyond the fruit; so keep on throughout the season.

Creepers for Shallow Basket.—*P. L. R.*—You do not say what size your basket is, nor whether it is indoors or outdoors.

"Hygeian Cook Book."—*T. Heath.*—We know nothing of the book further than that it was sent to us for review. We have already given the address of the publishers.

Pansies.—*Nancy.*—The blossoms were too much shrivelled for us to be able to judge of their merits. We cannot undertake to name florists' flowers, which can only be done by specialists who have the means of comparison.

Six Palms for a Cool House.—*C. B.*—Amongst the most suitable Palms for growing in an ordinary greenhouse are the followiug:—Areca Baurei, A. monostachya, Cocos chilensis, C. Procopeana, C. coronata, Chamærops Fortunei, C. humilis, C. robusta, C. tomentosa, Seaforthia

elegans, Thrinax parviflora, Kentia australis, K. Belmoreana, K. Fosteriana, K. Canterburyana, and Corypha australis. See them all at a nursery, and choose which you like best.

Ericas after Flowering.—*G. W. W.*—Cut out the weak shoots, and shorten back the strong ones to at least half their length. Place them in a cold frame and syringe them overhead occasionally, and be attentive to watering. When new growth commences, inure the plants to air and sun; and then in autumn, when the new growth has got a little firm, you may put in cuttings 1 in. in length in a pot of sandy soil in a close frame with a bell-glass over it. If the pots are now full of roots, the plants should have a shift into a size larger pots when new growth has fairly commenced, using tough peat and silver sand.

Worms in Plant Tub.—*Mole.*—Get a handful or two of slaked lime and put into a can of water; well stir it, and water the plant with it; or, what would be better still, place the tub in a large vessel, then pour into the vessel lime water till it reaches the rim of the tub; the worms will then come to the surface and can be destroyed.

Soil for India-rubber Plant.—*Experienced Wife.*—Any good soil will do for this plant, but the best is three parts turfy loam, one part leaf-mould or rotten cow manure, and plenty of silver-sand or river-sand.

Green Fly on Roses.—*E. J. J.*—Get some Quassia chips from the chemist, and boil them for a quarter of an hour, putting at the rate of 4 oz. of Quassia chips to 1 gallon of water. Strain off the chips, and whilst the liquor is cooling add 4 oz. of soft soap to the gallon. Syringe the trees with this; and half an hour afterwards syringe them with clean soft water. Several applications may be necessary.

Planting out Camellias.—*C. Andrews.*—Unless the plants are small, it would be better to plunge the pots in ashes in the open air than to turn the plants out of the pots.

Propagating the Lemon-scented Verbena.—Take off young shoots from plants that have been well exposed to sun and air, about 4 in. or 6 in. long, and insert them in sandy soil under a bell-glass in a moist frame, or in a shady window.

Saving Cyclamen Seed.—This should be gathered when the pods are ripe, but just before they burst open. It may be sown when gathered, or be kept till August. Sow in a pan of light friable sandy soil, and place in a warm greenhouse or frame under a bell-glass, or with a sheet of glass placed over the pan.

Yellow Grapes.—*Perplexed.*—We can assign no reason for the Grapes turning yellow from the description you give of the Vines.

Gardenia Leaves Turning Yellow.—*M. L.*—The leaves sent look as though the plant was starved for want of some stimulant. Apply a little weak soot water occasionally, and a little liquid manure or guano water when the buds are opening; also keep the plant well syringed.

Culture of Salsafy.—*Annita.*—Full details are given in GARDENING, June 28th, of last year.

Stagnant Water for Plants.—*Boz.*—Water that has been in a butt for a month or two may be safely used for watering plants or vegetables.

Scale on Maiden-hair Fern.—*E. Percy.*—Your only course is to cut the fronds all off close.

Cork for Growing Plants on.—*W. W. J.*—Consult our advertising columns.

A. J. J.—We know nothing of the manure to which you allude.

J. H., Stockport.—The leaves of the Cucumbers appear to be dried up, as if they had been covered with red spider. Remove the leaves a few at a time, and induce new growth to start.

Books.—*Scotia.*—We know of no good book on the subject you mention. There are some, but there are chiefly of a botanical character.

Names of Plants.—*Flora.*—Generally called the Artillery Plant (Pilea muscosa).——*Subscriber.*—The Fern alluded to must be Microlepia exserta.——*G. R. W.*—Pulmonaria officinalis.——*R. P. E.*—The drawing sent is of a Turk's-cap Cactus (Echinocactus) of some kind, but we cannot say which from a simple sketch. It will grow in sandy well-drained soil in a cool house.——*W. R. S.*—Bougainvillea glabra.——*A Novice.*—2, The Greater Stitchwort (Stellaria holostea); 3, The perennial Mercury (Mercurialis perennis).——*R. B.*—1, The Snake's Head (Fritillaria meleagris); 2, Kerria japonica.—*W. R.*—Berberis Empetrifolia, a hardy shrub.——*E. G.*—Cantua dependens.—*Dinder.*—Habrothamnus fasciculatus; other next week.——*E. G. B.*—Prunus padus, the Bird Cherry.——*Mrs. J. P.*—Varieties of Narcissus, Tazetta variety.——*E. M. M.*—A fungus peculiar to the Rose.——*S. W.*—The Corn-flower (Centaurea cyanus), a hardy herbaceous plant.——*H. H. H. H.*—Amelanchier Botryapium.——*L. G. B.*—Blue, Aubrietia deltoides; white, Arabis albida.——*J. B.*—Saxifraga cæspitosa——*Fred. Cockerell.*—We received your letter, but no Ferns.——*D. D.*—Phlox subulata.

QUERIES.

2245.—**Wall Climbers.**—Will some one kindly give the names of two or three best suited for back wall of lean-to greenhouse? The wall is a warm one, the kitchen fire being on one side of it; aspect, south-east.—J. M.

2246.—**Rhododendrons not Flowering.**—I take care to buy only those Rhododendrons that show a good promise of blossoms. They flower well the first season, and then, as a rule, afterwards throw out leaf buds only. I wish specially to know if they can be pruned with benefit, both as regards form and flowering; and if so, when and how?—W. E. CARR.

2247.—**Araucaria Losing its Branches.**—I have a fine Araucaria growing in a very sheltered garden and seemingly in good health; but all the lower branches on one side turn brown and many have fallen off. It is a very fine specimen, fully forty years old, and I should be much obliged for some advice on the subject; the decay seems spreading upward among the branches, but the stem is perfectly healthy and it grows freely. Would fresh top-dressing with good soil be likely to be of use?—AUNT FORTUNE.

2248.—**Pansies Deteriorating.**—Will a show Pansy deteriorate so long as all the blooms are picked off before opening? If the top be cut off a deteriorated Pansy, will the young shoots produce flowers perfect as at first? If roots of deteriorated Pansies be divided, will the divisions produce good flowers? Will cuttings of a deteriorated Pansy, or of a Pink which has lost its lacing, produce perfect blooms?—J. W. L.

2249.—**Manure for Plants.**—Is pig manure good for plants in pots? and, if so, ought it to be well rotted?—NANCY.

2250.—**Asparagus Beds.**—Could any reader of GARDENING tell me what it would cost to make an Asparagus bed large enough to supply five or six persons during the season? also, how soon the Asparagus would be fit to cut?—NANCY.

2251.—**Plants for Sunless Windows.**—What plants or flowers will succeed in my back windows, which look north? They have plenty of light, but no sun; one is a well-warmed kitchen. Geraniums are useless, as they will not flower. Situation: Glamorganshire, and very cold in winter.—RED ZYONITE.

2252.—**Hardy Perennials.**—Can any one give me a list of a few choice hardy Perennials of easy culture and showy appearance, for sowing in July or August, of compact growth?—RUSTIC.

2253.—**Fern Cases.**—Will some one tell me how to construct a Fern case, and how to provide proper drainage? and is a flat or slanting roof the best?—G. C. G.

2254.—**Plants for Window Boxes.**—I should be glad to know what plants would be most suitable to put in window boxes in a fortnight's time. The aspect is a north one, and dusty from the street. I want something that will last till the frost comes; foliage plants I like, and last year I had Pyrethrum (yellow), and it looked well, as the boxes are peacock blue.—BROWN-EYES.

2255.—**Hollyhock Leaves with Red Spots.**—My seedling Hollyhocks are not thriving; they were sown last spring, and put in their places a month ago. As the leaves attain maturity they become spotted with small red protuberant spots on the underside (like Radish seed), flag, and gradually decay. I have manured with soot and liquid manure. What is the disease, and the remedy?—R. H. P.

2256.—**Fennel-root as a Substitute for Celery.**—I am told that in Italy, especially in the large cities, the smell of Fennel pervades the streets just after noon, arising from the preparation of the root for use after dinner as we use Celery, and that it is relished by high and low. The roots are grown there of immense size. Can any correspondent who has travelled and dined in that country give an opinion as to whether this root would be admissible at an English table, how it is served up, and with what eaten, and any hint as to the growth of luxuriant roots?—R. H. P.

2257.—**Orinthogalum arabicum.**—I planted half-a-dozen bulbs of this plant in 5-in. pots last autumn, and every one started into vigorous growth, but not one of them shows any signs of sending up its flowering stem. This same failure to make this lovely plant to bloom has happened to me before; and I would feel obliged if any of your numerous readers who may have been more successful can suggest the cause? I must add they were planted at the same time, and treated in every respect in the same way, as a Hyacinth bulb.—LEWIS W.

2258.—**Planting a Rockery.**—I read with much interest the article on rock gardens a few weeks back. As my space was limited, I made up my mind to make a miniature one. The only situation was at the bottom of my strip of garden, which is shaded from the sun till the middle of the day this time of the year by a neighbour's house. With a few barrowloads of loam and leaf-mould I made a bank 7 ft. long, 2 ft. high, and 3 ft. wide at base, and in it partly buried some rough pieces of broken millstone. As the space is small, I should like to grow only the best; and as easterly winds blow along it in spring, I should be glad if some reader would give me the names of the most beautiful Alpine plants sufficient and suitable for the size and situation of the rockery.—ALPINE.

2259.—**Narcissi Failing.**—We have a nice lot of double white Narcissus, but out of the seven or eight years we have had them they have only borne a few flowers twice. I got them all up and divided them several years ago, but that did not do them any good. They grow in light sandy soil in different positions. One under a south wall bore two or three flowers last year. This year the same root put up about a dozen buds, but within this last week they have all withered off in the same way that they have done other years. Will some one kindly suggest a remedy?—FLORA.

2260.—**Wallflowers not Blooming.**—Last July I sowed some seeds of Wallflowers. When the young plants were large enough, I transplanted them to a cold frame, where they remained during the winter. About two months ago I planted them out in the open, and, although they have grown considerably, they have not yet bloomed, nor are there any signs of their doing so.—H. BROADWAY.

2261.—**Watercresses.**—I have a small stream at one end of my land, which might be made to cover half an acre of ground. Can any of your readers tell me what profit per year might be reasonably expected by the culture of Watercresses; also, if I can employ any simple method of throwing the water back to its highest point, in order to extend the beds?—QUIVER.

2262.—**Uses of a Cellar.**—What profitable use might I make of a good cellar other than for Mushroom growing?—QUIVER.

2263.—**Jonquils and Tulips.**—I planted a number of Tulips and Jonquils last autumn, and only a few of the Tulips have bloomed; so I have removed them from the ground, well dried them, and intend storing them away till next planting time. All Tulip bulbs appear sound; but the Jonquils, without one exception, have long tap-roots, and appear to have been growing downwards. Will some one inform me if this is usual; also the best thing to do with them to secure blooms next year?—AMATEUR B.

2264.—**Cleaning Stone Vases.**—In the garden we have two vases (Maltese stone). Would some reader kindly inform as to the best means of cleaning them?—H. H. L.

2265.—**Tacsonia Van Volxemi.**—Will some one tell me how to treat this creeper when growing in a greenhouse? Ought young plants to be cut back after blooming?—D. T.

2266.—**Fowls' Manure.**—I have a quantity of fowls manure, and should be obliged if some one would tell me what is the relative strength of such material, and how to apply it to various crops. Is it good for watering Onions and flowers?—A. N.

2267.—**Do Ferns require Sunshine?**—Finding there is a great diversity of opinion concerning the treatment of Ferns in this respect, I shall feel obliged if some of your many readers will give their experience; also the names of those Ferns (if any) which thrive best in the sunshine.—W. HEWES.

2268.—**Sawdust for Blanching Celery.**—Would sawdust answer for the purpose named?—J. D.

2269.—**Pruning Fruit Trees and Shrubs.**—Will some one kindly inform me the best time to prune Apple and Pear trees (pyramids), Laurustinus, Euonymus, Holly, Laurels, Rhododendrons, &c., and how to do so?—E. J. H. C.

2270.—**Bottom Heat for Frames.**—Would "Petros" be so kind as to tell another reader what quantity of oil his lamp would burn in a week? He advises "F. H. W." a tin lamp to hold 2 quarts; if it burns that in twenty-four hours it would come rather expensive for a labouring man. It is Paraffin he burns, I suppose; and that is 4d. per quart where I live. If the lamp burns 2 quarts per day it would make 14 quarts per week. I shall make one myself after I have got a right understanding.—W. S. J. D.

2271.—**Oleanders not Blooming.**—We have a large Oleander of considerable age, kept in bay window; aspect south-east; in winter the room is heated with fire. The plant grows vigorously, and forms a continuous succession of buds, which fall almost before commencing to swell. Only one year in four or five will we get half-a-dozen blooms. Young plants struck from it will flower strongly one season, perhaps two. Could any of your correspondents say whether we should have a better chance of bloom if its growth was stopped during the winter? It has good soil; do they require it very rich?—V.

2272.—**Gooseberry Trees with Rank Growth.**—My gardener has cut my Gooseberry and Currant bushes so that they have made, especially the former, the most luxuriant shoots; so that they are fine specimens of rank growth. What should be done? Of course, there is little fruit The main branches are a mass of succulent lateral shoots.—H. A. W.

2273.—**Shrubs for Cold Locality.**—I have a large garden bordered by shrubs of all except flowering kinds. I am wishful in the autumn to replace some of the worst of those remaining by some very good ones of the flowering and ornamental kinds, and think it best to see them in bloom or foliage at one of the nurseries before I purchase them. Will some one favour me with a list of such shrubs suitable for a cold elevated position facing south, but yet on the side most open to the east wind? I want about twenty. The soil is light on gravel.—H. P., *Edgbaston.*

2274.—**Rose Tree not Growing.**—I have a white Rose tree which bloomed beautifully last summer in a sitting-room window with south-east aspect. About six weeks ago I cut it back and repotted it in a size larger pot. I shook out old stuff from its roots, and put loam and leaf-mould; but I find the wood turns yellow and the leaves have a sickly look. Will some reader kindly tell me whether I have taken a right or wrong course in the treatment?—BERT.

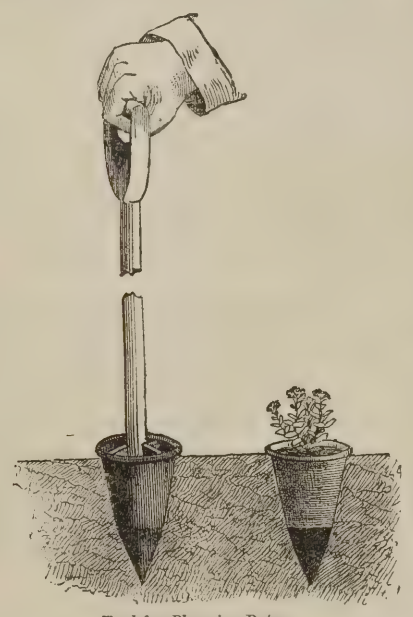
2275.—**Insects in the Fern Case.**—I have a Fern case which is infested with a small white insect. I should be glad to know it this insect injures the Ferns in any way; and if so, how can I get rid of it?—F. THOMAS.

THE HOUSEHOLD.

Unwholesome Preparation of Food.—From the numerous dishes recommended in almost every newspaper, one would be led to suppose that the genuine old-fashioned system of cooking is imperfect. In days gone by we were satisfied with a variety of good food, well cooked. Now our system is changed entirely, and not the true cooks, but the ladies of leisure, seem to be vyeing with each other how to invent the most costly, unhealthy, indigestible food, with which to torture our poor stomachs and deplete the purses of the brain-working dyspeptics. If the majority of the persons who thus sin knew how much they sin, I feel quite sure they world be cautious how they recommend a compound which is alike costly and fearfully destructive to the health of all who partake habitually. I sincerely hope our good wives will cease to exhibit so much folly as they do by their constantly flooding the papers with imaginative delicacies, which in their effect upon the persons who indulge in them are little, if anything, less

than slow poison. This is especially so with regard to our cakes, pastry, and similar things. Any man or woman who invents anything which helps us to live better and more happily, is in the truest sense a philanthropist and a blessing to mankind. Any man or woman who invents anything for the use of mankind which is injurious, or in any way deleterious, is guilty of a great wrong, and should stop and think. Many persons, of course, recommend things through ignorance, not knowing the chemical poison contained in the food recommended. Out of seventy-four different ridiculous fashionable foods recommended, I found only four which were free from saleratus, and any one who constantly uses saleratus pays a fearful penalty. The stomach becomes eroded, and the nervous system is completely broken down.—WM. HORNE, V. S. in *Country Gentleman*.

Implement for Plunging Pots.—This is a useful garden tool. Its handle, as will be seen, is like that of an ordinary spade, and the base consists of a heavy cast-iron dibber, shaped to make a hole to hold a pot, leaving a vacuum below for drainage purposes, and to prevent worms from entering the pots. This implement is only made to suit 4½-in. and 3-in. pots; but it could be made to suit any sized pot, and the handle might be of any required length. In



Tool for Plunging Pots.

using it, it should be plunged into the ground up to the rim, giving it a slight turn round so as to throw off any earth adhering to it; then withdraw it, and insert the pot as shown in our illustration. The weight of the implement soon makes the desired hole with but little exertion on the part of the operator, if the ground is at all pliable, and the expedition with which the work is preformed soon repays the cost of the instrument. For plunging Tomatoes, Vegetable Marrows, and Cucumbers in frames in market gardens, before they are finally planted out, this tool would be very serviceable; and in nurseries, where greenhouse plants in general, herbaceous and alpine plants, &c., are so extensively plunged out-of-doors in summer, it will be found to be indispensable.

POULTRY.

Disease in Fowls.—I am experiencing the same kind of bad luck in my poultry yard as recorded by "Violet" in GARDENING, May 8th. A few days ago one of my best laying Houdan hens was observed to be a little giddy, refusing its food, but thirsty, and avoiding its companions. The next morning it was found dead, with its feet and legs spasmodically and firmly contracted, and drawn up against its body. On examining it, I found it was extremely fat and heavy, but there was no appearance of vermin among the feathers, nor did it appear to have been egg-bound; but the skin generally had a dark congested appearance, as if it had died in spasms. My own impression is that death was caused by a general spasm of the system ending in a kind of apoplexy, but how produced I am at a loss to understand. If any one can afford me any information which may tend to lessen the chances of the entire destruction of my flock—which at present, like "Violet," I have too much reason to apprehend—I shall be glad. I should mention that my fowls have been largely fed upon fat kitchen refuse and waste Potatoes. I have ordered the quantity of this kind of food to be diminished, and, with a view to relieve the vascular condition of the system, have ordered them to have a mixture of barley-meal warmed with Cayenne pepper, which I trust will be followed by good effects.—AMATEUR.

Fowls Eating Eggs.—I have some game hens that were constantly eating their eggs. I cured them in the following manner:—I got two or three of the eggs and "blew" them (that is, cleared out the shells), and filled them with mustard mixed in the ordinary way, making up the ends with plaster. I left them in the nests, and they partly disappeared, but it entirely cured the hens of the bad habit.—H. B. L.

Vermin on Fowls.—"Viola" should at once construct a small covered dusting-place for her fowls, and fill it with ashes and cinders, so arranged that the fowls get a depth of 6 in. or 8 in., at least, to dust in. They soon become infested with vermin without this. I should also add to the Oats a little Maize and Tail Wheat, and give occasionally a little boiled liver or chandlers' greaves, and some roughly-pounded bones. Sick fowls must be removed from the others, and overcrowding at night guarded against; it is a fertile source of disease.—C. H.

Fowls with Dark Combs.—I have some silver-spangled Hamburgh fowls whose combs are quite dark, almost black in fact. Can any one tell me whether this is a disease or not? The birds appear remarkably healthy and lay well.—F. F.

Featherless Fowls.—My hens have all more or less lost their feathers under their tails; in some cases the tail, half of the back, and body are quite without feathers except the few tail feathers. The hens are laying, so I shall also be glad to know if the eggs will be unwholesome in consequence.—F. R. C.

Swellings on Fowls.—I have a Brahma cock that has no wattles, but in place of same it has in the throat a red bladder the size of an egg. Can any reader inform me whether this is natural, or whether it is a disease, and if contagious? I have only noticed the swelling quite recently.—AMATEUR.

Hatching Turkey Eggs.—Is it safe to hatch turkey eggs under a hen? if so, is it too late in the season?—S. LEE.

BEES.

Supers.—The time for putting on supers is in May and June, when the combs are filled with brood and honey; also four or five weeks after swarming if the weather is favourable and the honey harvest abundant. Bees seldom store honey in supers before the hive is filled with comb, or so long as there are empty cells in the hive; should the hive swarm when supers are being filled upon it, the supers should be taken off at once, or the bees will quickly transfer the honey stored in them to the cells then being rapidly emptied of brood, through not having a pregnant queen to keep up the supply of eggs.—SAMUEL YATES, *Manchester*.

Are Bees Profitable? Is there any profit to be derived from keeping bees in the neighbourhood of London? I should like a practical apiarian to give a few hints on this subject.—W. B.

HOME PETS.

Acclimatised Canaries.—It may be interesting to some of your readers to know that canaries are not such delicate birds as is often supposed. True, many die from catching cold; cages are hung up in a room, and when the little songsters are exposed to draughts from the door or window they die, and are thought to be very tender. Well, mine have been out-of-doors all this winter, exposed as they were to a frost which on two or three occasions has registered from 12° to 20° below zero. The aviary is about 9 ft. high, 12 ft. long, and 6 ft. wide, covered with a zinc roof, and has a wall on the north, east, and west sides; the front, facing the south has no protection whatever during the most intense frost, except a quarter-inch wire netting. Night and day, sunshine and shade, some have been there year after year, and never yet have I found that cold or frost has been the destruction of one. Some young and some old, it makes no difference as far as the thermometer is concerned: they roost on the dried stumps or branches inside, and never sing more sweetly than during the winter snowstorms. Like children, they seem to derive amusement from the falling snow. The birds like eating snow too. When the frost is so severe that the water freezes almost as soon as it is given to them, which has been the case this winter, I take care to shovel some snow into the cage, and so long as they have snow to pick, or water to drink, they do not mind the cold. They enjoy a cold bath, however, as long as the frost does not prevent them having a dip, which, by having a little water only on the top of the ice, they were long able to do, till at last the ice in the pan was one frozen mass and they had to satisfy themselves with the snow. Turn your canaries out-of-doors in the warm air of July or August, and as the cold of winter comes on gradually they will month by month get accustomed to it. My experience for years has proved that if they are protected from a draught or current of air through the aviary, you may fearlessly expose them to any amount of cold such as can get to them from a southerly aspect, protected (only to prevent them flying away) by a wire netting.—W. BUDDEN, *Ipswich*, in *Science Gossip*.

Rabbits.—What are the most hardy and profitable rabbits to keep? Is groundsel injurious to them?—F. A.

Rearing Hares.—Feed it frequently with milk from a spoon. Later on it will eat Lettuce leaves and other green stuff. A friend of mine has one brought up in this way. It is particularly fond of Primroses; it eats bread also, and is quite tame.—T. H.

Budgerigars.—The birds are both males. The nose of the female is a light buff or fawn colour. The breeding season commences in December, and continues until the moulting season, about August. They will not breed until they have been two years in confinement.—H. D. F. D.

—"M. F.'s" birds are both males. The hen is distinguished from her mate by the absence of the blue on the beak, otherwise the plumage is identical in both sexes. When they are acclimatised they begin nesting arrangements about the same time as canaries; but newly imported specimens are very irregular; they may begin at any time of the year. When they are about to do so the cock continually feeds the hen. It is very important to keep them well supplied at this time with green food.—A. D'A.

Lice on Canaries.—I have an excellent canary whose cage has lately become infested with small insects, which, I am afraid, will worry the bird. Will "A. D'A.," or some other correspondent inform me of a remedy?—L. R. F.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 3s to 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus, 4s to 9s; Pelargoniums (zonal), 3s to 6s.; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Camellias, 1s to 4s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses (forced), 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Deutzia gracilis, 9s to 18s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 3s 6d to 7s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 6d.

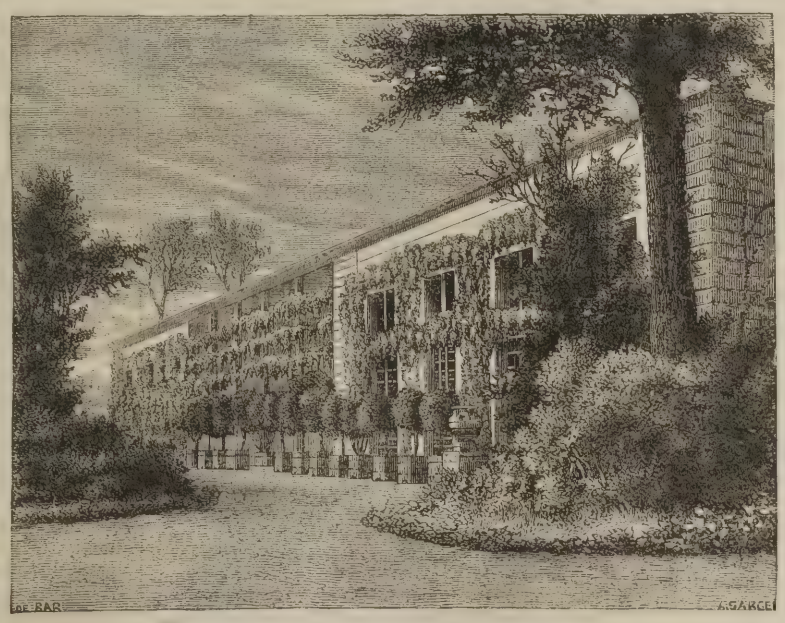
Vegetables.—*Per 100.*—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 9d to 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 3d to 5d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Saveys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

GARDENING ILLUSTRATED.

VOL. II.—No. 65. *SATURDAY, JUNE 5,* 1880. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

THE WISTARIA.

As this grand hardy climber is now coming into bloom, it seems an opportune time to say something of its culture. It is well known to be one of the finest hardy plants for covering walls, cottages, trunks of trees and other bare spaces, whilst when grown in pots in the form of standards for the decoration of large conservatories in early spring it is an excellent plant. When the Wistaria is used for covering the side of a house or to form a summer-house, or afford shade to a balcony, some definite system of training should be adopted in so far as to decide what piers or columns are to be covered, and whether the plant is to be trained along the cornice or to be carried yet farther upward to screen a window. When this is done and the necessary rods or wires have been provided, the proper shoots for the use required should be selected, and thereafter all others that may interfere with the design to be carried out should be rigorously cut away. A system of pruning nearly similar to that of the spur system in Grape Vine pruning should then be adopted—or rather a system combining that with the system generally adopted for fruit trees which bear their flowers and fruit on old spurs.



HOUSE COVERED WITH WISTARIAS.

The Wistaria, though a climbing plant like the Grape Vine, produces its flowers from old spurs like a Cherry, a Plum, a Pear, or an Apple tree. In July or August all shoots or eyes on the main or leading stems that may be reserved should be pinched back to within 1 ft. of the main stem, in order to check the rampant growth. These shoots will again break into growth from the buds just behind where the shoot was stopped off; and after they have grown a few inches in length they should also be stopped in the same way. The result will be the formation of flower spurs at the foot of the shoot first shortened. Early in the succeeding spring these shoots are to be cut back to within five or six eyes of the main stem, and the young shoots from these eyes are then to be treated in the same way as those of the previous year—and so on, year after year. By following this course of treatment, long continuous wreaths of flowers will be produced. When the leading stem or stems have reached the length it is intended they should attain, they should also be stopped, and the final effect will be an orderly and trim appearance of the plant, which yet will not appear formal and stiff. Treated thus, the Wistaria may also be grown on the lawn, or as a specimen plant in the shrubbery—either on single stems or as ordinary shrubs with several stems. The Wistaria will thrive in any ordinary garden soil, providing it is well drained. Like all other climbing flowering plants it well repays any little extra pains that may be bestowed on the planting. The soil should be taken out to a depth of 18 in. or 2 ft., and should be turned over several times at intervals of a week, so that it may become thoroughly sweet and mellow. At the same time some well-rooted manure may be added to it, and if the soil is naturally of a light description, an admixture of sandy loam would also prove beneficial. If, on the contrary, the soil is of a stiff, tenacious character, mix with it some leaf-mould or wood ashes, and if possible a little mortar rubbish, or small pieces of brick. In such a compost the Wistaria will grow amazingly. The width and length of the border thus made must be left to the discretion of the operator—who should, however, bear in mind that all plants are benefited by an extended root room in congenial soil.

CAMELLIAS OUT-OF-DOORS.

I HAVE been much interested in the articles of late upon the hardiness and culture of the Camellia. It is a matter of surprise that growers of this very beautiful evergreen do not exercise a little more courage than they have hitherto done, and follow the example of a gentleman residing here, who owns a property near the sea, and who has made the cultivation of the Camellia a speciality. In conversation with him he tells me he has the finest collection of Camellias in Europe, numbering something over 260 varieties. These I have had the pleasure of seeing on several occasions when in full bloom. Some of these Camellia trees—for I can call them nothing else—average from 25 ft. to 30 ft. high, and, during the spring months, are literally covered with splendid bloom. One in particular during my visit claimed my attention: it was the fine old C. alba plena. The worthy proprietor told me that he had attempted to count the blooms on this one tree that morning, and having got as far as 1500 he gave it up, feeling convinced that the tree had considerably over 3000 blooms upon it. Many of the trees in this lovely garden have boles 12 in. to 15 in. in circumference. I regretted much to see a fine row sawn down to make room—the roots and about 2 ft. of the stem being left, each of which measured 12 in. in circumference. The trees when growing averaged from 18 ft. to 20 ft. high. The bill-hook and saw are frequently in requisition, the trees making such free growth. I asked the owner about

the growth these Camellias made annually. He replied that it depended upon the sort; some were rather slow, but many made shoots 12 in. or more per annum. Being fond of the Camellia he has them trained against the walls; and here it is a sight once seen never to be forgotten. Some hundreds of yards of wall 12 ft. high are covered with every beautiful variety a refined taste can select, nothing inferior being allowed anywhere. Hundreds of visitors call, and are abundantly supplied with baskets full of perfect blooms, the esteemed owner being prodigal in his gifts of the Camellia. It is "cut and come again if you want more;" and yet with all this liberality no blanks or empty space is made. The soil of which this garden consists is a black loam, resting on a clay bed. The garden is well sheltered by various evergreen and deciduous trees, but withal the proprietor tells me that in some winters he has lost many evergreens, such as Laurels, Laurustinus, and Escallonias by frost, but never a Camellia, which has been equally exposed. This I can endorse, having seen several evergreens killed to the ground this severe winter; but in no case have I seen a Camellia suffer even so much as burnt foliage. There is no secret about the cultivation of the Camellia; it is simply planted out like any other shrub in the ordinary garden soil. For the first year the plant makes but little growth, owing to its having been grown under glass before purchasing. The second year the shrub moves a little faster; and by the third season it is fully established, and then grows as fast as a Laurel. These outdoor Camellias are more prolific of bloom, and for quality and shape are not to be equalled by any grown under glass. This may be due to increased vigour, but one drawback is their coming out when hoar-frost or heavy rains are frequent. Even with this disadvantage the Camellia, as an evergreen shrub or tree, in beauty of foliage, symmetrical growth, and hardiness, holds second place to no other; and though the expanded blooms may be injured by frost or rain, such is the abundance of buds that it is only for a day or two and the trees are beautiful again. I say to all readers of GARDENING ILLUSTRATED, try outdoor cultivation, and do not expect much for the first two or three years—it is not thought much to wait that time for many other trees to become established—then plant and have patience, and in due time you will reap your harvest of lovely Camellia blooms. OMEGA.

A Hardy Edging Plant.—As a permanent edging, from 1 ft. to 2 ft. in width, to beds or borders of shrubs, either in place of a Grass verge or margin, or just inside the turf when turf is used, Mahonia repens may be effectively employed. Two or three year seedlings, planted in two or more lines 6 in. apart, will, with a little attention and management, make an edging superior to Ivy and most other materials commonly employed. Although not at all particular as to soil, it, like everything else, does best when well treated; therefore the ground shonld be trenched up and well-prepared some time before planting. The plants may be planted deeper than is desirable with most hard-wooded plants, as it will soon strike root from the buried portions of the stems. It will bear trimming in with the shears, but it is far better to do the necessary pruning with the knife, as the leaves that remain are left intact, and will not present a ragged appearance as when the shears are used. It may be kept for years in a dwarf compact condition, by cutting well back every spring after flowering, and pinching out the point of a shoot occasionally during the summer. Of course, this close cutting back would prevent its fruiting; but, although this might in one respect be a loss, in others it would be a gain, as a heavy crop of fruit has a tendency to exhaust the plants, and might cause them ultimately to assume a ragged outline, which, in the case of a verge or edging of this kind, would not be desirable. Although I have only spoken of this plant as useful for verges or edgings to shrubberies, it might also, now that advantages of introducing more variety of a less ephemeral nature into the flower garden is beginning to be recognised, be used as edgings next the Grass, in either a straight or any other outline. If this and other plants of a kindred character were more used, there would not be such a dreary blank when the frost came; and with a few additions from the reserve garden of spiral-growing plants, with bulbs and annuals, a very respectable winter display might be got together with little expense. But when nothing but tender plants are used for bedding, and these have to be entirely replaced, any attempt at winter or spring gardening becomes expensive.—H.

Privet Hedges.—As a division between compartments in kitchen gardens or allotments there are few more serviceable hedges than those made of Privet kept cut down tolerably low, say so 3 ft. or 4 ft. If clipped early, say in the first or second week in June and again in August, they become densely furnished with young spray-like growth, and remain quite covered with green leaves the whole season; but if left uncut until the end of the summer the whole of the undermost leaves are lost, and after cutting, a bare stubby aspect is the result, altogether spoiling the general appearance of the hedge.—J.

VEGETABLES.

HOW TO GROW COLEWORTS.

IN mid-winter, when fresh green stuff is more or less scarce, the Colewort, owing to its tender juicy nature, proves a most delicious dish, and amply recompenses anyone for the little care that is necessary to procure it in good condition. Great exactitude is required as to the time of sowing; in this particular point lies the mainspring of success, and a little divergence in this respect either one way or the other will suffice to entail disappointment. In Colewort culture there is always a danger of running to extremes: either the plants may not have time to heart sufficiently, or they may run too much to head, in which case they are more susceptible of injury in inclement weather. Now, as the sowing time falls just in the height of summer, when the attention is apt to be distracted therefrom by press of work, it often happens that the proper moment passes unawares. Then, again, the weather being often very hot and parching, the seed, in the ordinary way of sowing, does not germinate quickly, thereby creating such a loss of time as cannot possibly be recovered. The seed should be sown not later than the first week in July, and it is not advisable to be much earlier in so doing, as if the sowing and planting be done then, there will be just the proper time to bring the heads to the desired substance.

The seed should be soaked for forty-eight hours before sowing; in the meantime, let a piece of good mellow soil be prepared, and draw some drills therein about 9 in. apart. If the weather be very dry, water the drills well before sowing the seed in them, which it is not well to do very thickly, as, if the seed be good, nearly every grain will come up. When sown, the bed should be covered with a few boughs, which will exclude birds and help the soil to retain its moisture. In a few days the seed will be coming through, when the shading must be removed. By this manner of sowing success is ensured, even in the most trying weather; in fact, owing to the heat of the soil, germination takes place more rapidly in a dry time. As soon as the plants have acquired sufficient strength, they should be planted out upon a piece of moderately rich ground, in rows about 1 ft. apart and 9 in. from plant to plant. It is as well to make two plantings, drawing out the strongest plants first, and leaving the remainder for a week to gain strength. It sometimes happens, too, that it is hardly possible to attend to them all, but if a portion be thinned out the rest may stand without injury until it is convenient to plant them.

A good watering now and then in the earlier stages of growth will be found beneficial, and the soil should be well stirred amongst them, keeping them free from weeds. They are liable to the attacks of a brown grub, which eats them off at the collar. When this is perceived they must be looked over now and then and the maggot destroyed; it will generally be found concealed just under the soil close to the stem. A dressing of soot is of great service in keeping them away. A few plants should always be kept in hand to fill up the blanks thus created. In mild and ordinary winters the Colewort will stand uninjured, and may be cut fresh and tender the whole winter through. There sometimes comes a season, however, when they get entirely destroyed. Those who would like to save their crops which they have been at the pains to grow should endeavour to secure a little protection for them. This is best effected by taking them up and laying them in a sheltered place where they may be covered in very severe weather by a few shutters or some Fern. This really delicious vegetable is worth taking some pains to secure, and it is no small satisfaction in a severe winter, when green vegetables generally are scarce and of poor quality, to be enabled to keep up a supply of tender Cabbages.

Radish Roots and Pods.—Although these are commonly used in mixed pickles, it is rare that they enter into the ordinary pickling conserves of the domestic household. They are, however, singularly pleasant eating even in a raw state, and might be well mistaken for crisp young Radishes, as they have the flavour and gentle stimulating heat of that root when in its young state. The seed pods of the long white Californian kind are peculiarly good, and would make, if served up when young, a useful adjunct to the breakfast or tea table. To have these in abundance at this time of the year seed of this Radish should be sown in a drill about the middle of September, and the plants will get large enough to stand the winter well. In good ground the produce of pods in the spring will be so considerable that it may with frequent gatherings be extended over several weeks, whilst the plants will need Pea sticks or cords for their support. In pickling, nothing further is necessary than to strip off the points of the pods, and then treat them as Gherkins, Onions, or other subjects, are prepared. To get good roots of the white Californian Radish, seed should be sown at midsummer, as it will then be found that large fleshy roots for winter consumption can be had in abundance. Grown quickly, it is very crisp and pleasant, and makes a capital winter salad.—A.

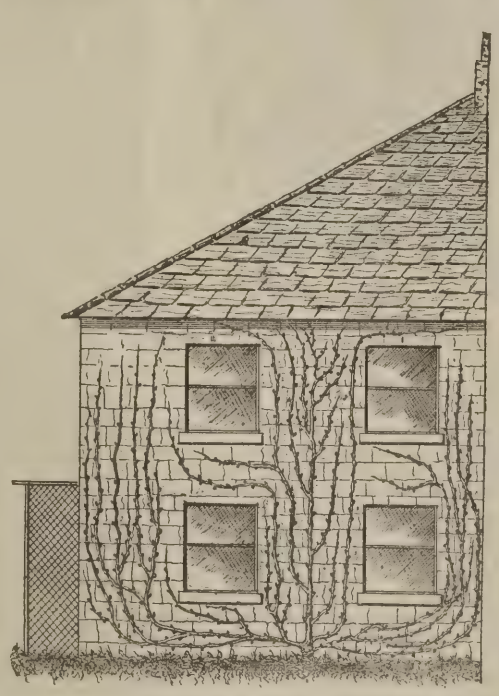
Vegetable Marrows.—These are plants the culture of which might be profitably extended in small gardens, not only for use as vegetables in summer, but also when fully grown and ripe to form a preserve for tarts and puddings during the winter. Where land is scarce they may be planted near to and trained over the faggot-heap, or up the sides and over the roof of any low building with a favourable aspect. Open holes for them from 6 ft. to 8 ft. apart, and 3 ft. in diameter by 2 ft. deep; fill up with anything that will ferment, and furnish a slight bottom-heat in which to start them; and that will be sufficiently decomposed when the plants commence bearing and require support to supply them with food. There is nothing better than the manure from a pig-stye or cow-house, and this may be eked out with weeds, short Grass, or trimmings of any kind that can usually be met with in every garden. When the holes are filled in level with the surface and made firm, the earth should be formed into a hill with a hollow in the centre, into which the plants or seeds should be set. If there be a frame or pit, the seeds may be sown in small pots about the middle of April, and planted out about the middle of May. It is hardly advisable to sow them in heat, the probable effect of which treatment being to draw the plants up weakly, unless they are removed to a cool frame as soon as they

are up. There is a far better prospect of a crop from strong vigorous young plants raised in a cold frame than from larger plants raised in heat. Where there is no convenience in the way of glass the seeds may be sown on the hills—three seeds to each hill—in May, and an inverted flower-pot placed over them; or plants can generally be purchased for a few pence. When the young plants break through, the flower-pots must be removed in the daytime and replaced over them at night until all danger from frost is over, until they become too large to be so covered. There are other simple contrivances that may easily be improvised to shelter in spring not only Vegetable Marrows, but many other subjects requiring protection. When the plants begin to run they should be pegged out, and the strongest shoots occasionally stopped, so as to fill up all vacant spaces. It is an excellent plan to mulch the ground occupied by the Marrows with long littery manure, or anything that will keep the earth cool and moist—which treatment will save labour and materially benefit the crop. In dry weather copious waterings, with occasional supplies of liquid manure, will be very serviceable to the plants; they will add much to their productiveness and discourage the attacks of mildew. But there will be less necessity for this if the ground can be heavily mulched. The Long White Vegetable Marrow is the best and most profitable kind to grow. When used as a vegetable it is best cut before it gets too large. Later on in the season two or three may be left for preserving for winter use, but the large ones rob the plants more than the same weight of small ones do; therefore they should not be allowed to attain a large size till the plants are very strong and well able to support them.

FRUIT.

VINES ON OPEN WALLS.

In reply to your request to explain Hoare's (long rod) system of growing the Grape Vine on open walls, I propose to commence with the accompanying sketch, showing how Vines are usually trained on small suburban or country houses. One entire side of a house is thus commonly given up to a single plant, and it is not uncommon to see two and sometimes three sides covered in like manner, the greater part of the growth being beyond the reach of a person standing on the ground. By training as in this sketch ("How not to do it") the cultivator has the maximum of trouble and labour and the minimum of fruit; as with such an array of old wood on the walls, all of which has to be annually nourished, the young canes upon which the fruit is borne are too much sheltered to be properly ripened, and the most of the small quantity of fruit that is grown is borne upon the canes farthest removed from the root, and the most inaccessible to the cultivator for the purpose of thinning, bagging, &c.



How *not* to do it. Fig. 1.

The instances of large crops of Grapes taken from Vines covering a large extent of walling are very rare. I know several Vines reputed to have yielded a hundredweight of Grapes in one year, but have never seen one that could be estimated at more than a third of that quantity. Moreover, instead of being an annually increasing crop, as it must be by Hoare's system, it is known that a good return ought only to be expected occasionally, when the Vine has had a few years' rest, and when an exceptionally hot summer occurs. In the above sketch the pruning by the spur method would take about 400 cuts with the pruning knife unless the operator had the sense to substitute a few of the best young canes for some of the old wood, leaving from fifteen to twenty eyes in each, instead of shortening them like the smaller twig-like growths to two or three eyes. But it must be remembered that whether 300 or 400 wounds are thus made the effect on the constitution of the plant is very serious, and this cannot be shown to be necessary.

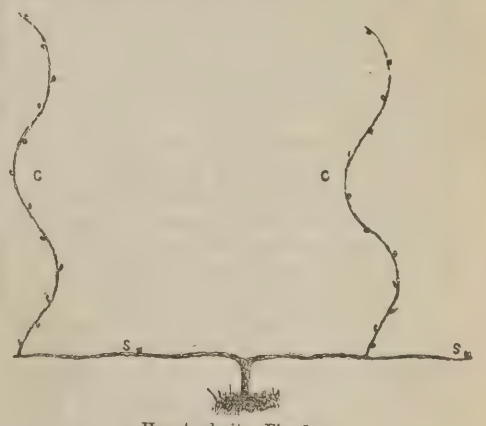
Let me suppose that your readers have planted some young Vines last October. By Hoare's system they should then have been pruned to two eyes only. The cut is to be made from the opposite side from the second bud, and 1 in. beyond it, in an upward direction, with a very sharp knife. One of the two shoots that push from these buds is to be retained after July 1 next, and the other then cut out. Any other shoots which may appear are to be rubbed off. On Nov. 1 the Vine is to be again cut down to two eyes. The roots should be covered with manure from November 1 till March 1. The next year is the third year of the Vine's age, and the same management has to be pursued as the previous year on July 1, choosing the best of the two canes, and sacrificing the other. If any fruit shows pinch it off immediately. On Nov. 1, the Vine being 2 in. in circumference at the ground, it is to be pruned to three eyes, as two shoots are to be permanently retained for next year. The roots require again to be covered with manure till March 1. The fourth year the young shoots must be very carefully trained to the wall, and on July 1 the weakest of the three is to be cut out. On September 1, pinch off the tops of the shoots. This will cause the buds remaining to gain strength until November 1. when the shoots are to be pruned to seven eyes. The Vine now consists of stem and two canes, and requires no more old or parent wood until it is nearly twenty years old. The girth of its stem is now 3 in., and in the next year it may be permitted to bear fruit not exceeding 5 lb. weight.

As encouragement to adopt this system, I may mention that an annual increase of girth amounting to ½ in. may be expected, and that every such ½ in. means another 5 lbs. of Grapes; so that at 16 years of age the Vine should be 8½ in. in circumference, and mature 60 lb. weight; and this leads me to point out that Mr. Hoare claims that the Vine is the only fruit tree that will in this climate in the open air, south of 54° latitude, produce its annually increasing crop without fail.

The young Vine may now be said to enter on its fifth year, and consists of a short stem of old wood and two young canes each containing seven buds. On February 1, or as soon as the weather is open, remove these canes carefully from the wall, and cut out the first, second, fourth, fifth, and sixth buds; then bend these shoots down to a horizontal position and securely nail them to the wall, as shown in figure 2. On May 1 train the two shoots that push from the buds 3 and 7, as the dotted lines 1, 2, 3, 4. On September 1 pinch off the tops of the shoots to let the sap accumulate in the buds below. Take your 5 lb. of fruit from the shoots Nos. 2 and 4; I recommend this as in

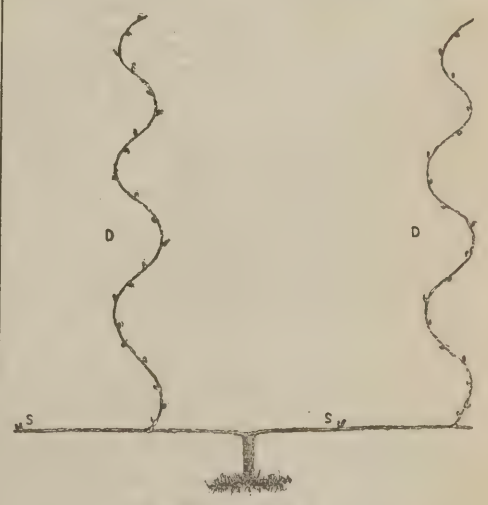
Fig. 2.

harmony with Hoare's teaching, although he does not give this instruction. These shoots have to be cut out, all but the lowest bud, as soon after October 1 as the fruit is ripe. Nos.



How to do it. Fig. 3.

1 and 3 are to remain on the wall all the winter, and be the fruit bearers of the following year; and what is necessary is to have their wood and buds well ripened; therefore I recommend that



How to do it. Fig. 4.

they be not allowed to bear fruit the first fruit-bearing year, but that function assigned on Nos. 2 and 4 exclusively.

Liquid manure may be applied every second or third day during hot weather; blood is very valuable, but it must be quite fresh, and I think on one day in the year—say about June 1—quite enough. The best manure is bones—uncooked ones for choice—placed liberally along

with brickbats and old lime and mortar under the Vine when planting. Some time between October 1 and November 1, you cut out Nos. 2 and 4, leaving only the lowest bud on each; and you shorten Nos. 1 and 3 to, say twelve buds each. Ten would represent the proper number, as I shall try and show in my next, but say twelve in case of accidents. This makes twenty-four buds on these two canes, which, having been trained close to the wall during their growth, and only shaded by their own foliage, are thoroughly ripe, and can be depended upon for their 10 lb. of Grapes in the next (the sixth) year. On March, 1 the sixth year, the shoots or canes Nos. 1 and 3 are to be trained as in figure 3, where they are serpentined on the wall, as marked cc—to prevent the sap flowing too quickly to the furthest buds, and to ensure the lower ones their full share of nourishment.

I have always trained mine after the fourth year in this serpentine fashion while green and tender, and find the result such as to warrant my recommending it. It is difficult to bend and secure canes on the wall in a different shape from that in which they are grown; and few amateur gardeners would possess the skill and patience necessary to do so without injuring the precious buds.

But here we have arrived, as in figure 3, "How to do it," at the proper permanent shape of the Vine in full bearing. This sixth year the young canes are carefully trained which push from the spurs ss, occupying a clear space on the wall, not interfering with the fruiting shoots of last year's canes, cc, and not interfered with by them, and are carefully trained at full length until September 1st, when their tips must be pinched off to stop their growth, and prepare for the pruning or shortening in the following month.
